Subject: WTC Transportation Hub EIS

Hi,
I am looking for the Final EIS for the World Trade Center Transportation Hub. Would you be able to send me a copy or direct me to where I can find it?
Thank for your help.

Sincerely,
Alie

New York, NY 10271

Re: Freedom of Information Reference No. 15535

Dear Ms. Baumann:

This is in response to your December 3, 2014 request, which has been processed under the Port Authority's Freedom of Information Code (the "Code", copy attached) for a copy of "the Final EIS for the World Trade Center Transportation Hub."

Material responsive to your request and available under the Code can be found on the Port Authority's website at http://www.panynj.gov/corporate-information/foi/15535-WTC-1.pdf. Paper copies of the available records are available upon request.

Please refer to the above FOI reference number in any future correspondence relating to your request.

Very truly yours,

Daniel D. Duffy
FOI Administrator

ABSTRACT

The Federal Transit Administration (FTA) and The Port Authority of New York and New Jersey (PANYNJ), have completed a Final Environmental Impact Statement (FEIS) and Section 4(f) Evaluation for the Permanent World Trade Center (WTC) PATH Terminal, a project involving the reconstruction of a permanent terminal at the WTC site in Lower Manhattan for the Port Authority Trans-Hudson (PATH) system. The Permanent WTC PATH Terminal is proposed to be a full service, regional transportation hub that would be coordinated with the existing and future transportation infrastructure, WTC site development, and the surrounding area. The project is needed to re-establish and enhance transportation facilities and infrastructure that existed at the WTC complex prior to September 11, 2001 and to ensure the long-term accessibility and economic vitality of Lower Manhattan.

The FEIS has been prepared pursuant to the National Environmental Policy Act (NEPA). The alternatives considered in the FEIS include a No Action Alternative, and a Preferred Alternative. The Preferred Alternative is carried forward for detailed evaluation in this FEIS after careful consideration of a range of alternatives as part of the planning for a Permanent WTC PATH Terminal and following public comments during the scoping process and public comment period for the DEIS. The analyses and impact assessments in the FEIS consider potential effects on transit service and transportation, land use and local planning, social and economic conditions, historic and archaeological resources, urban design and visual resources, air quality, noise and vibration, infrastructure and energy, contaminated materials, natural and water resources, coastal zone management, safety and security, and cumulative effects. Environmental Performance Commitments, preliminary sustainable design guidelines, and mitigation measures to reduce impacts, including stipulations set forth in the Project's Memorandum of Agreement pursuant to Section 106 of the National Historic Preservation Act are described in the document.

✳

A. INTRODUCTION

The Port Authority of New York and New Jersey (PANYNJ), a municipal corporate instrumentality and political subdivision of the States of New York and New Jersey, is proposing to undertake, in cooperation with the United States Department of Transportation (USDOT), through the Federal Transit Administration (FTA), a project involving the reconstruction of a permanent terminal at the World Trade Center (WTC) site in Lower Manhattan for the Port Authority Trans-Hudson (PATH) system. The Permanent WTC PATH Terminal is proposed to be a full service, regional transportation hub that would be coordinated with the existing and future transportation infrastructure, WTC site development, and the surrounding area. The project is needed to re-establish and enhance transportation facilities and infrastructure that existed at the WTC complex prior to September 11, 2001 and to ensure the long-term accessibility and economic vitality of Lower Manhattan.

The Project would be funded as part of the Federal government's $4.55 billion Lower Manhattan Transportation Recovery Effort, which was committed to New York City following the terrorist attacks of September 11, 2001. The FTA will be the federal lead agency for the environmental review of this project to be undertaken in cooperation with PANYNJ. As such, this Environmental Impact Statement (EIS) is being prepared in accordance with the National Environmental Policy Act (NEPA; 42 USC §§4321 et seq.) of 1969 and the applicable regulations implementing NEPA as set forth in 23 CFR Part 771, 40 CFR Parts 1500-1508, and 49 CFR Part 622. This EIS is also being prepared in accordance with Section 106 of the National Historic Preservation Act (NHPA; 16 USC §470(a)) of 1966 and Section 4(f) of the USDOT Act of 1966 (49 USC §303) and other environmental laws and regulations.

B. PURPOSE AND NEED

Trans-Hudson transit service between New Jersey and New York has long been an integral part of the Lower Manhattan transportation system. Prior to the terrorist attacks of September 11, 2001, the WTC PATH Terminal served some 67,000 daily boardings and was the gateway to Lower Manhattan for most commuters from west of the Hudson River. However, the attacks resulted in extensive damage to the PATH system including the destruction of its WTC Terminal. As a result, the system lost a significant portion of its capacity to serve commuters throughout the New York and New Jersey region and mass transit access to Lower Manhattan was severely hindered.

PATH is an electrified, heavy-rail transit system with a total of 13 stations in New York and New Jersey. It is a wholly-owned subsidiary corporation of PANYNJ and is recognized as a commuter rail system under the oversight of the U.S. Department of Transportation, Federal Railroad Administration (FRA).

The WTC PATH Terminal, which opened in 1971, was located beneath the WTC's office and retail space, in the portion of the site referred to as the "bathtub." Its platform level contained three 10-car platforms and five tracks. Trains entered the station from New Jersey via the south Hudson River tunnel (Tunnel F) and exited to New Jersey via the north tunnel (Tunnel E). Thus, the platform level formed the loop in the PATH system allowing trains to enter and leave Manhattan without changing the location of the train's engineer or conductor. As a result, trains could have a short dwell time at the Terminal.

A mezzanine was located above the platforms, housing vertical circulation, fare equipment, and accessory retail and food stalls. The retail concourse, known as PATH Square, provided for all-weather connections between PATH, the office buildings on the WTC site, the World Financial Center, New York City Transit (MTA/NYCT) subways, and street level.

The WTC PATH Terminal and a seven-car PATH train were destroyed as a result of the terrorist attacks of September 11, 2001. Tunnels E and F under the Hudson River were flooded, and PATH's Exchange Place Station in Jersey City, New Jersey, was damaged and rendered inoperable because the track configuration would not allow trains to turn around before entering the Hudson River tunnels.

PANYNJ began construction of a temporary PATH station at the WTC site in July 2002, shortly after control of the site was returned by the City to PANYNJ. The station opened on November 23, 2003. It is located in the WTC "bathtub" and has five tracks and three 8-car platforms. Street level access is through a single entry/exit at the intersection of Fulton and Church Streets. There are also direct connections to two MTA/NYCT subway stations.

Although the temporary WTC PATH station allows for service to Lower Manhattan, it does not fully restore the pedestrian connections or the capacity that existed before September 11, 2001.

PROBLEM IDENTIFICATION

ECONOMIC RECOVERY

Transportation links have been critical to the commercial development of Lower Manhattan. Service between New Jersey and New York has been integral to the movement of employees to and from their Lower Manhattan offices. More recently, employment centers have emerged in Jersey City and Newark. These businesses depend on PATH to deliver workers from New York City and other points east of the Hudson River. Furthermore, several major businesses have located facilities in both Lower Manhattan and Jersey City, allowing for office expansion while maintaining a close connection between company functions on both sides of the River.

A successful economic redevelopment of Lower Manhattan requires the replacement and enhancement of transportation facilities that were lost or damaged on September 11, 2001. Some 15 percent of Lower Manhattan's workforce lived in New Jersey prior to September 11, 2001 and the WTC PATH Terminal was the busiest of downtown's transit stations. Although other currently planned transportation projects would improve access to and from Lower Manhattan for those commuting to and from New Jersey, none offers the direct and high-capacity linkage that can be served by PATH and the proposed Permanent WTC PATH Terminal.

In a survey of 25 executives of major employers located in Lower Manhattan, a Permanent WTC PATH Terminal was identified as "extremely" important to the future economic health of Lower Manhattan (Alliance for Downtown New York, Inc., April 2003). If such a facility were not provided, the full potential of Lower Manhattan's revitalization may never be realized.

RIDERSHIP GROWTH

Lower Manhattan is a vital component of the New York economy. It is second only to Midtown Manhattan in terms of gross floor area of office space, and it is a growing residential neighborhood and retail destination.

Prior to September 11, 2001, businesses in the area south of Canal Street employed more than 388,000 workers. Approximately 15 percent of Lower Manhattan's workforce commuted from west of the Hudson River and transit was their predominant mode of travel. The physical loss of office and commercial space on September 11, 2001, coupled with a general economic downturn, resulted in a reduction of 80,000 jobs in Lower Manhattan. Most of the office space damaged or destroyed on September 11, 2001 will be replaced by 2015. In addition, a memorial, cultural facilities, and retail space will be constructed on the WTC site that will attract visitors in addition to the anticipated return of office workers.

It is estimated that PATH's daily ridership at the WTC would be 175,000 by 2025, which would exceed the capacity of the temporary station. Therefore, without a permanent terminal, the PATH system cannot adequately support the planned redevelopment of the WTC and the overall revitalization of Lower Manhattan.

COMMUTING TO LOWER MANHATTAN WITHOUT PATH

Immediately following September 11, 2001, commuters formerly using the PATH WTC lines were forced to seek other routes or modes of travel to reach destinations in Lower Manhattan. As a result, there were significant ridership increases on Trans-Hudson ferries, uptown PATH lines, and NJ Transit commuter rail. Although these modes have enabled commuters to reach Lower Manhattan, they do not have the capacity or the flexibility to serve as a long-term alternative to a Permanent WTC PATH Terminal.

Although ferries have served as an important interim mode of travel for Lower Manhattan's commuters, they would not serve long-term travel needs between New Jersey and Lower Manhattan. Ferries have a much lower capacity than heavy-rail. While the location of ferry terminals may be convenient for those who work along Water Street and at the World Financial Center, others must walk much farther to reach interior destinations than was required with PATH service. Furthermore, most ferry passengers must transfer to one or more additional modes within New Jersey during their commute. During heavy rain storms or when the waters of the Hudson are icy, the ability to maintain ferry service is constrained.

Following the destruction of the WTC PATH Terminal on September 11, 2001, ridership at PATH's Christopher and 9th Street Stations doubled during peak periods. Both the Christopher and 9th Street Stations have a limited capacity. To immediately address these problems, PANYNJ had to limit station access during certain hours. Although upgrades are planned for these stations, they will not have adequate capacity to support general PATH system growth if a Permanent WTC PATH Terminal is not constructed.

Following the terrorist attacks, ridership on NJ Transit commuter rail increased by approximately 30 percent, requiring additional trains on its routes serving New York's Pennsylvania (Penn) Station, precluding certain service enhancements planned for that system. For example, the full opening of the Secaucus Transfer, which provides a link between the Northeast Corridor line serving Penn Station, and the Main and Bergen County lines that serve Hoboken, was delayed until temporary PATH service was restored. Furthermore, NJ Transit and Amtrak share the rail lines that traverse the Hudson River between New Jersey and Lower

Manhattan and service is limited by the capacity of the single rail tunnel. Thus, if permanent PATH service is not restored to Lower Manhattan, there may not be additional capacity to support passengers that would be diverted to commuter rail, thereby reducing the utility of the Secaucus Transfer and potentially limiting options for future system improvements.

LIMITATIONS OF TEMPORARY PATH SERVICE

To expedite the restoration of PATH service to Lower Manhattan, PANYNJ designed and built, on a fast-track basis, a temporary station. The temporary station was a commitment to restore the facilities damaged by the terrorist attacks and it was determined to be a catalyst to restore and redevelop Lower Manhattan by providing commuter service from west of the Hudson River. To ensure the speedy restoration of PATH service, the temporary station was constructed in essentially the same location as the pre-September 11, 2001 Terminal. This allowed PANYNJ to reuse certain infrastructure elements including the 1 and 9 underpass, portions of the retail concourse, and the MTA/NYCT subway station connections that remained on the WTC site. Furthermore, design documents could be advanced more quickly since track and platform configurations and other station elements could be constructed based on pre-September 11, 2001 plans. However, to achieve this commitment within two years after the attacks, PANYNJ compromised certain elements of the pre-September 11, 2001 Terminal with regard to operational capacity, service amenities, and pedestrian connections.

Because PANYNJ could use as-built plans from the pre-September 11, 2001 Terminal to design and construct the temporary station, extensive survey work was not needed. Designers could lock in the station and track configuration both horizontally and vertically. As such, steel detailing could be expedited and steel sizing accelerated. Since it was intended as a temporary station, platforms were designed to be removed and not integral to the platform walls; interior drainage was less than desired since only the outer bay of the station has interior drains; and, roof insulation was minimal since it is an outdoor facility open to the elements.

The temporary station has 8-car platforms as compared to the 10-car platforms that were part of the pre-September 11, 2001 Terminal, resulting in 20 percent less operational capacity. Prior to September 11, 2001, PANYNJ was studying the extension of stations along its Newark-WTC route to provide for 10-car train service. These improvements were in response to ridership levels that were reaching maximum capacity on this route during peak periods.

Some of the infrastructure elements within the station have a limited service life. The vertical elements, while ADA-compliant, do not provide a sufficient level of service to accommodate future demand. Escalators from the platform to the mezzanine level and from mezzanine level to the MTA/NYCT 1 and 9 subway line underpass were not provided. The station's design does not allow for new construction above, as planned for the WTC redevelopment, nor can it easily support connections to future buildings on the WTC site or other off-site destinations.

To expedite service restoration, the temporary station's tracks and platforms are located outdoors in the WTC "bathtub." Weather protection is provided, but the station is not fully enclosed and is not climate-controlled. Local radiant heating is provided in waiting areas, but many portions of the station complex are not heated during winter months or cooled during summer months.

The temporary station includes security and fire protection equipment, but advanced passenger amenities are not provided. The station is ADA-compliant, but its configuration requires four separate elevator rides to reach street level. Emergency exits are provided, but they lead

passengers either to Church Street or to the WTC bathtub area with access to the street via the temporary access ramp and a temporary stairway to West Street.

Because construction of the WTC site is ongoing, pedestrian access to the temporary station is limited as compared to the pre-September 11, 2001 Terminal. All patrons enter and exit at street level near the intersection of Church and Fulton Streets at the eastern boundary of the WTC site. Thus, patrons traveling to the World Financial Center must double-back along Vesey or Liberty Street. The temporary station has connections to MTA/NYCT's E, R, and W lines, but access to 1 and 9 subway line is not available because MTA/NYCT's Cortlandt Street Station has not yet reopened. As such, two fewer subways are served compared to pre-September 11, 2001 conditions.

CURRENT PLANNING CONTEXT

Since September 11, 2001, several projects have been planned that are independent of the Permanent WTC PATH Terminal but that also aim to redevelop and revitalize Lower Manhattan. Presently, four environmental reviews have been prepared under NEPA independent of this EIS as follows:

- World Trade Center Memorial and Redevelopment Plan: The U.S. Department of Housing and Urban Development (HUD) and the Lower Manhattan Development Corporation (LMDC) have prepared an EIS for the redevelopment of the WTC site, which includes a memorial and memorial-related improvements, commercial, retail, and hotel space; museum and cultural facilities; new open space; new street configurations; and certain infrastructure improvements at the WTC site and adjacent parcels. HUD and LMDC published a Final Generic Environmental Impact Statement for the World Trade Center Memorial and Redevelopment Plan in April 2004, and a Record of Decision was issued in May 2004.

- Fulton Street Transit Center (FSTC): FTA and the Metropolitan Transportation Authority (MTA) have prepared an EIS for the Fulton Street Transit Center project, which would rehabilitate, reconfigure, and enhance the multilevel complex of subway stations serving nine different lines in the area of Fulton Street and Broadway. The facility's proposed Dey Street concourse would connect with the MTA/NYCT subway station at Cortlandt Street (R and W lines), the WTC site, and the Permanent WTC PATH Terminal. FTA and MTA published a Final Environmental Impact Statement for the FSTC in October 2004 and a ROD was issued in November 2004.

- Route 9A Project: The U.S. Department of Transportation, Federal Highway Administration (FHWA) and the New York State Department of Transportation (NYSDOT) are considering alternatives for the reconstruction of Route 9A south of Chambers Street. This project would include at-grade improvements or a below-grade bypass for vehicular through traffic. A supplemental EIS is currently being prepared for this project. FHWA and NYSDOT published a Draft Supplemental Environmental Impact Statement for the Route 9A Project in May 2004. FHWA has not yet formally determined a Preferred Alternative for the Route 9A project. The State of New York has recently indicated a preference for the Route 9A At-Grade Alternative. A FEIS on this project is expected to be published in late spring or summer 2005 and select a preferred alternative. This FEIS addresses environmental impacts of the range of alternatives identified in the Route 9A DEIS.

- South Ferry Terminal: FTA and MTA are preparing an Environmental Assessment for the reconstruction of the South Ferry Terminal on the 1 and 9 line. This project would increase

both the capacity of the Terminal and the 1 and 9 line during peak periods. FTA and MTA published an Environmental Assessment for the South Ferry Terminal in May 2004 and a Finding of No Significant Impact was issued in August 2004.

Before September 11, 2001, several projects were planned downtown that are still under study. These include residential development projects and commercial buildings at Battery Park City and within the Washington Street Urban Renewal Area, open space and cultural institutions, and modest commercial development. Following September 11, 2001, federal, state, and local initiatives have been implemented to encourage private development in Lower Manhattan. These programs provide funds for commercial and residential and encourage the construction of community facilities, open space, and infrastructure in support of the area's redevelopment and recovery.

Although these projects would rehabilitate transportation facilities and would support an economic recovery for the area, none of them offers a high-capacity link between New Jersey and Lower Manhattan.

PROJECT GOALS

The Permanent WTC PATH Terminal would be a full-service, regional transportation hub that would be coordinated with existing and future transportation infrastructure, WTC site development, and the surrounding area. The project is needed to re-establish and enhance transportation facilities and infrastructure that existed at the WTC complex prior to September 11, 2001 and to ensure the long-term accessibility and economic vitality of Lower Manhattan. To that end, the selected project alternative must successfully address four goals.

- Effectively restore long-term PATH service between New Jersey and Lower Manhattan;
- Establish an intermodal transportation facility in Lower Manhattan;
- Plan and construct a Terminal that would support the redevelopment of Lower Manhattan; and
- Minimize adverse impacts to the environment.

C. PROJECT ALTERNATIVES

Project Alternatives for a Permanent WTC PATH Terminal were identified as part of early planning studies conducted by the PANYNJ following the terrorist attacks and through the public scoping process for this EIS. After careful consideration of these options, three alternatives were carried forward for further study in the Draft EIS (DEIS) as follows:

- No Action Alternative;
- Terminal with Liberty Plaza Connection Alternative; and
- Terminal without Liberty Plaza Connection Alternative.

The planning and design of a Permanent WTC PATH Terminal is being closely coordinated with the other Lower Manhattan recovery efforts described above. In order to plan for potential changes in these independent projects that may require alterations to the construction and/or operation of the Permanent WTC PATH Terminal, the DEIS identified design options for the Terminal. These design options and their potential environmental effects were described in the DEIS.

Furthermore, under the guidance of various federal agencies, the sponsors of the Lower Manhattan recovery efforts have coordinated to develop Environmental Performance

Commitments (EPCs) and Green Design and Sustainability Guidelines to be incorporated as part of their individual projects. These measures aim at proactively addressing potential adverse effects to the environment in order to reduce the impacts to the local community and the region as a whole.

Following the public comment period on the DEIS, FTA and PANYNJ selected a Preferred Alternative for the Permanent WTC PATH Terminal. The selected alternative was the "Terminal without a Liberty Plaza Connection" with some modifications to reflect current planning for the WTC site as well as the design options that would be part of the Project.

ALTERNATIVES DEVELOPMENT PROCESS

LOCATIONS FEASIBILITY ANALYSIS

While planning for the restoration of temporary PATH service to Lower Manhattan, PANYNJ was concurrently planning for a permanent facility, including tracks, platforms, mezzanines, pedestrian concourses, and a terminal building on or near the WTC site. Not only did PANYNJ intend to restore the capacity and connectivity that existed within the pre-September 11, 2001 WTC PATH Terminal but also wished to enhance pedestrian connections through the site and adjacent properties and to create a world-class transportation hub for Lower Manhattan. To that end, PANYNJ conducted an analysis of alternatives for transit service between New Jersey and Lower Manhattan.

Although the WTC Terminal was destroyed and the Hudson River tunnels were damaged as a result of the terrorist attacks, much of the PATH system remained intact. Thus, PANYNJ made the early decision to preserve as much of the PATH system as possible as part of their long-term planning for service to Lower Manhattan. It was decided that future service to Lower Manhattan should use the existing Hudson River tunnels and their projections within the WTC site. Because an alternate mode of transit would not be compatible with the remainder of the system, it was also decided that future service should be heavy-rail with PATH's specifications. Furthermore, PANYNJ considered constraints on PATH's alignment from other infrastructure within Lower Manhattan. Given these constraints, the only reasonable alternatives would be alternate locations for a Lower Manhattan PATH terminal.

Once PANYNJ identified that restoration of PATH was the only reasonable alternative for transit service between New Jersey and Lower Manhattan, they began planning for a location for the facility. To facilitate this process, planning guidelines were developed to further refine the Project's goals and objectives that were identified above. These planning guidelines allowed location options to be closely compared in order to weigh the benefits and potential shortcomings. Ultimately, a successful terminal location would not only restore service but would provide for enhancements as compared to the pre-September 11, 2001 facility. These planning guidelines were as follows:

- Create a World-Class, Transportation Facility;
- Support the Redevelopment of Lower Manhattan;
- Provide for Improved Pedestrian Connections;
- Provide for Advanced Security;
- Enhance Pre-September 11, 2001 PATH Operations;
- Support 10-Car PATH Trains, in order to support ridership growth;
- Minimize Impacts to Temporary PATH Service during Construction;

- Minimize Impacts to the Local Environment during Construction; and
- Minimize Construction Cost and Duration.

PANYNJ initially identified four sites of an appropriate size and configuration for a permanent PATH terminal. These locations are shown in Figure S-1 and are described below.

- Location 1, WTC "Bathtub" would restore service in the location of the pre-September 11, 2001 station by overbuilding the tracks, platforms, and mezzanines atop the temporary PATH station.
- Location 2, Church Street, would be a new facility in the approximate location of the former H&M Terminal.
- Location 3, Broadway-Nassau would be a new facility located east of the WTC site under Dey Street and beneath the FSTC.
- Location 4, Vesey Street, would be a new facility located on the northern portion of the WTC "Bathtub" along Vesey Street.

After careful consideration of these sites, it was determined that the construction at Locations 3 and 4 would result in long-term disruption of temporary PATH service. Furthermore, Location 3 would reduce the operating capacity of the PATH system and may require acquisition and/or demolition of existing buildings. Because these locations would not meet the Project's goals and objectives, they were considered seriously flawed and were not carried forward.

Location 1 (WTC "Bathtub") and Location 2 (Church Street) were evaluated more closely to determine their comparative benefits and faults. It was determined that Location 1 would be less expensive with a shorter construction duration than Location 2, and it would allow for more flexibility in the redevelopment of the WTC site. However, Location 2 would have closer proximity to many of Lower Manhattan's major destinations and transportation facilities and would have superior operations as compared to Location 1.

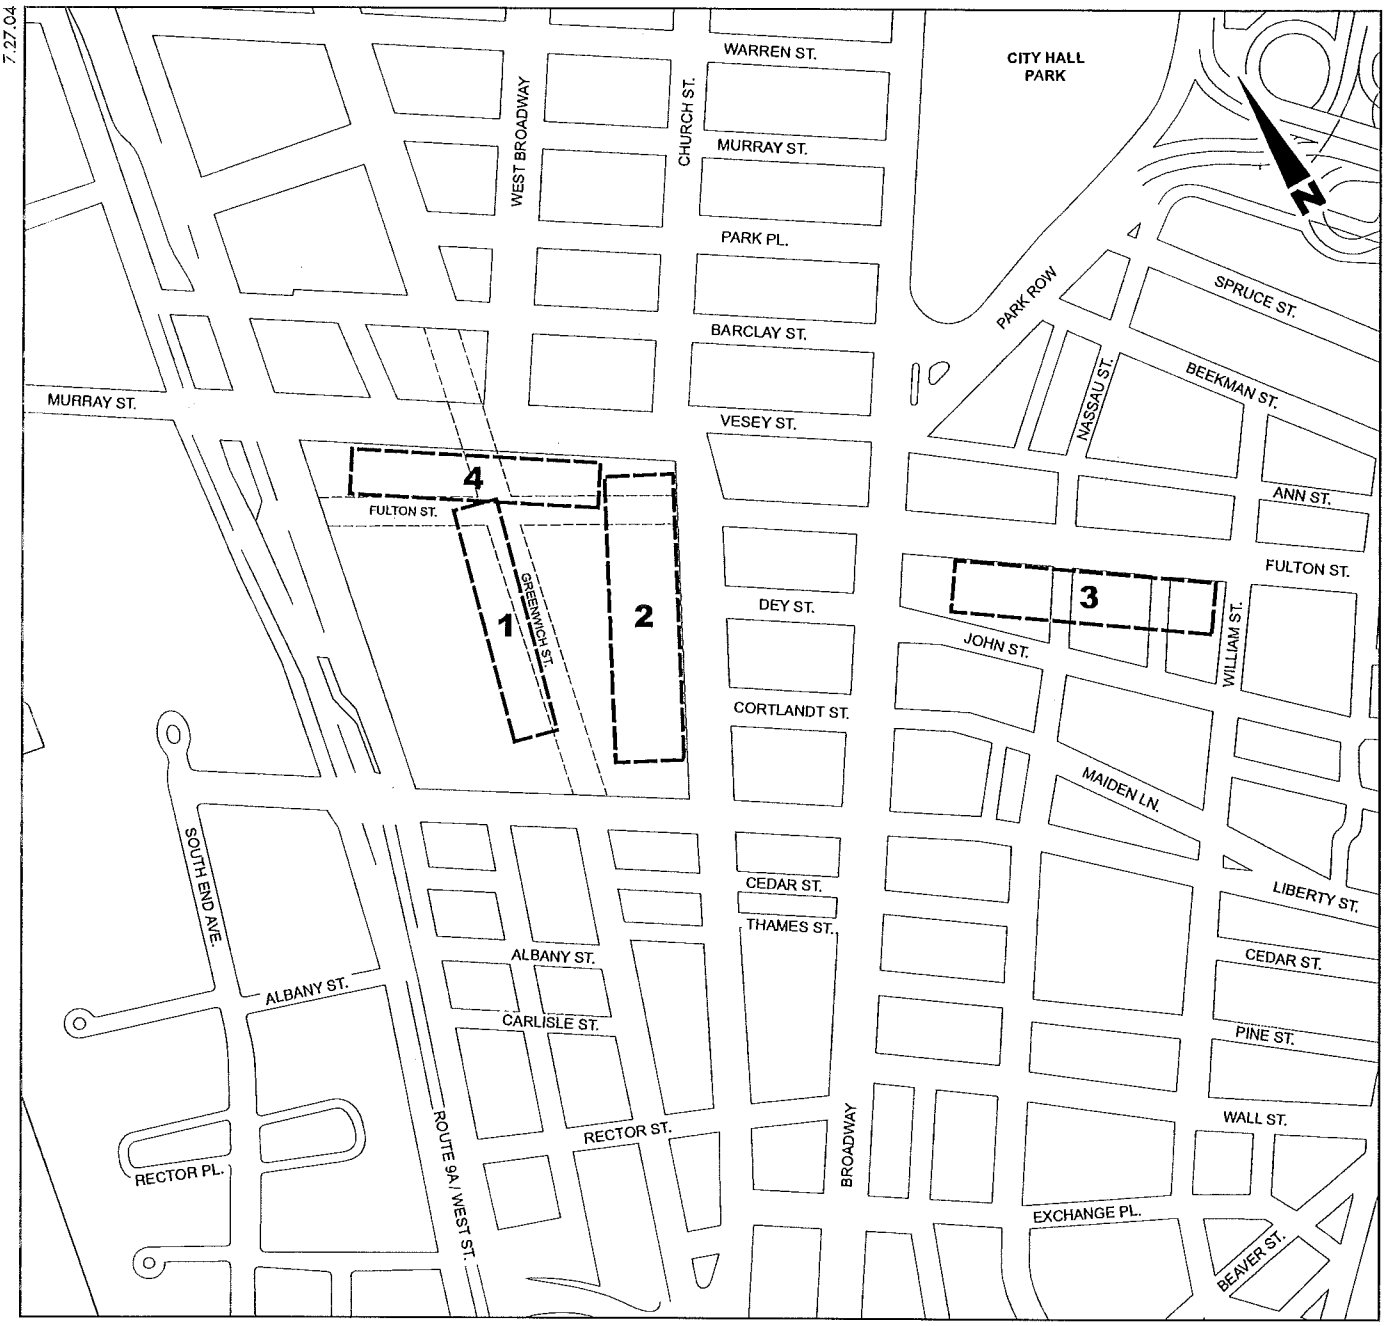
In recognition of the respective benefits of both Locations 1 and 2, PANYNJ worked to develop a plan that would combine the flexibility for overall site redevelopment with superior pedestrian connections and operations. As the master plan for the WTC site was advanced, the Permanent WTC PATH Terminal plan was revised to combine elements of both Locations 1 and 2. Under the "hybrid" option, the PATH tracks, platforms, mezzanine, and portions of its pedestrian concourses would be located in the WTC "Bathtub". The remaining portions of the pedestrian concourses and the terminal building would be located on the eastern portion of the WTC site along Church Street. Because this option balanced goals of the WTC site redevelopment with superior PATH operations, it was carried forward for further consideration in this EIS.

ALTERNATIVES CONSIDERED AND ELIMINATED

PATH-6 Train Connection

During the scoping process, public interest groups and local elected officials suggested an alternative that would connect the PATH system with MTA/NYCT's 6 line. PANYNJ considered their proposal and determined that a number of critical engineering and design issues would need to be resolved to make this alternative feasible which would likely delay the completion of this project, result in substantial alterations to existing and planned transportation infrastructure in Lower Manhattan, and have potential short- and long-term adverse impacts on

7.27.04



1 Alternative Location and Reference Number

Proposed New Street (To be Constructed by Others)

PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure S -1
Alternative Locations

historic resources. Due to these constraints, this alternative was not considered to reasonably meet the goals and objectives and was, therefore, not carried forward for further consideration.

Terminal with Liberty Plaza Connection Alternative

The DEIS considered a Terminal with a Liberty Plaza Connection Alternative. Generally, the Terminal with a Liberty Plaza Connection Alternative would result in the same facility as described below for the Preferred Alternative. However, it would include an additional pedestrian connection under Church Street between the WTC site and Liberty Plaza Park. The analysis presented in the DEIS showed that the Terminal with a Liberty Plaza Connection Alternative would result in vibration impacts on a greater number of historic structures, would result in temporary lane closures and pedestrian diversions on Church Street, and would have increased emissions and noise levels during construction as compared to the Preferred Alternative. In the long term, the Terminal with a Liberty Plaza Connection would divert pedestrians from street-level to a sub-grade concourse, which could detract from local businesses, and it would reduce the availability of open space within Liberty Plaza Park.

During the public review process for the DEIS, public officials and concerned citizens stated that the Liberty Plaza Connection would adversely impact community character. A public goal for the rebuilding of Lower Manhattan has been to revive its retail and to ensure its longevity as a 24-hour community. Citizens and agency officials believed that the diversion of pedestrians from street-level to the underpass would detract from this goal. Upon further consideration, PANYNJ decided to eliminate the Liberty Plaza Connection as part of the Preferred Alternative.

DESIGN OPTIONS CONSIDERED AND ELIMINATED

The DEIS presented options for the design of certain components of the Permanent WTC PATH Terminal. As planning has advanced, certain components of the project have been finalized such that design options could be dropped from further consideration. The following describes the options previously presented and the outcome of the design process that has occurred since publication of the DEIS.

Stand-Alone Terminal

The construction of the Preferred Alternative would be closely coordinated with the construction of elements of the WTC Memorial and Redevelopment Plan. However, a Stand-Alone Terminal option was developed to determine the design and cost implications absent elements of the WTC Memorial and Redevelopment Plan. However, a Record of Decision was issued for the *WTC Memorial and Redevelopment Plan, Generic Environmental Impact Statement*, in May 2004 and LMDC has been developing plans for the Memorial and uses on the eastern portion of the WTC site. PANYNJ has been working closely with LMDC to coordinate the subgrade infrastructure to ensure that the construction of the Preferred Alternative would not preclude future uses on the WTC site. As such, the Permanent WTC PATH Terminal would be coordinated with elements of the WTC Memorial and Redevelopment Plan. However, given that WTC site development plans may be delayed or may change over time, PANYNJ may advance certain components of the Terminal as integrated and others as stand-alone. This Final EIS (FEIS) generally considers the benefits and impacts of an integrated Terminal; however, where Permanent WTC PATH Terminal elements may be stand-alone to advance its design and construction, the potential environmental effects are noted.

Route 9A Pedestrian Bridge

The design of the Permanent WTC PATH Terminal's connection to the World Financial Center must be coordinated with the selected alternative for the Route 9A Project. As described in the DEIS for the Permanent WTC PATH Terminal, PANYNJ considered a pedestrian bridge over Route 9A as an alternative to a subgrade concourse in the event that the relocation of utilities beneath Route 9A would not be undertaken by NYSDOT. However, since publication of the DEIS, PANYNJ has determined that a subgrade concourse could be constructed at a lower elevation, which would avoid utility relocation regardless of the selected alternative for the Route 9A Project. As such, the Route 9A pedestrian bridge has been eliminated from further consideration as part of this FEIS.

South Ventilation Structure

The DEIS identified two options for the location of the Terminal's south ventilation structure—Route 9A median and Deutsche Bank. Under the Deutsche Bank option, PANYNJ would construct the ventilation system within the new office tower planned for the former location of Deutsche Bank. The vent would be at a minimum height of 40-feet above ground and would likely be constructed within a mechanical level of the future building. Because of the proposed building's distance from the PATH tunnels, a vent structure at this location would not be collocated with emergency egress. Therefore, PANYNJ would need to provide for an emergency stairway with access from the planned plaza adjacent to the office tower or within the north or south sidewalk along Liberty Street. As such, this option would result in additional PATH structures and may increase the overall project cost. Subsequent to the publication of the DEIS, PANYNJ has selected the Route 9A option for the south vent as the Preferred Alternative.

NO ACTION ALTERNATIVE

Under the No Action Alternative, PANYNJ would retain temporary PATH service between New Jersey and Lower Manhattan until either 1) elements of the WTC Memorial and Redevelopment Plan would preclude operations, 2) the station would not safely accommodate passenger demand, or 3) the major elements of the station would exceed their useful service life. It is assumed that as redevelopment efforts occur in and around the WTC site, modifications to the physical characteristics and operation of the station would be required to maintain temporary PATH service to the extent possible. These modifications, which would not involve federal funding, may include the construction of additional egress locations, new ventilation structures, and minor modifications to passenger areas.

As future increases in ridership place demand beyond the temporary station's design capacity, PANYNJ would need to implement operational adjustments to safely accommodate passengers. Two options would be considered to extend temporary service beyond its design capacity—reduced service and peak hour restrictions. Reduced service would reduce congestion and allow the platforms to be cleared of passengers before the next train arrives. Restricted access would prohibit customers wishing to travel from Lower Manhattan to New Jersey in the morning peak period from using the system in order to accommodate a greater number of passengers traveling from New Jersey. These options may result in the diversion of PATH customers to other modes of travel to and from Lower Manhattan.

Under the No Action Alternative, construction activities associated with the WTC Memorial and Redevelopment Plan, the Fulton Street Transit Center, South Ferry Terminal, the Route 9A Project, and certain private developments would occur on or near the WTC site. As such, certain

modifications may be required to maintain temporary PATH service and to ensure the safety of PATH riders as construction occurs around and above the station complex. Further modifications may also be necessary to extend the station's service life, but such activities would be comparable to the ongoing station maintain that occurs throughout the PATH system. Thus, the potential impacts of the No Action Alternative during the construction period would be far fewer and much lesser in magnitude that would be associated with the other project alternatives.

For purposes of analysis, it is considered that the temporary WTC PATH station would continue to operate in 2009 under the No Action Alternative. However, given the constraints identified above, it is not considered feasible to operate the temporary station through 2025. Thus, at some point between 2009 and 2025, the temporary WTC PATH station would be closed and PATH service between New Jersey and Lower Manhattan would cease to exist.

PREFERRED ALTERNATIVE

A coordinated effort between PANYNJ and LMDC was undertaken to develop a master plan for the WTC site to program uses for above and sub-grade levels. This effort was necessary to identify and assess the multiple interfaces and coordination required to fully redevelop the site. The elements of the future WTC site, including the Permanent WTC PATH Terminal and the WTC Memorial and Redevelopment Plan, would be fully coordinated both in terms of their function and their construction. Close coordination between the individual parties responsible for site components would be essential to effectively construct and operate the site. In many cases, construction activities would be planned to support two or more elements of the overall master plan. Although these projects are being pursued independently, they will continue to be closely coordinated.

The Preferred Alternative would result in a new Permanent PATH Terminal on the WTC site. This alternative was developed through an evaluation of the benefits and constraints of two Terminal locations, WTC "Bathtub" and Church Street, and it combines an above-grade terminal building and sub-level pedestrian concourses on the eastern portion of the WTC site with additional pedestrian concourses, tracks, platforms, and a mezzanine on the western portion of the site (see Figure S-2).

PRELIMINARY DESIGN

The Preferred Alternative would have five levels—platform, mezzanine, concourse (main), concourse (balcony), and street-level.

The platform level would be located immediately west of MTA/NYCT's 1 and 9 train line and atop the concrete slab at the base of the WTC "Bathtub." The platforms and tracks would have a north-south orientation to complete a loop with the Hudson River tunnels, similar to the configuration of the temporary WTC PATH station. The Preferred Alternative would have four platforms (Platforms A through D) and 5 tracks (Tracks 1 through 5). The four platforms would be long enough to accommodate 10-car trains in accordance with PATH's long-range goal to increase the operational capacity of its system.

The mezzanine level would have a north-south orientation and would be located directly above the platform level. This level would house fare equipment, vertical circulation to the platforms and concourse level, and up to approximately 5,000 square feet of retail services, such as newsstands and food stalls. The mezzanine level would have two entrances/exits to the above concourse level. An east entrance/exit would direct passengers beneath MTA/NYCT's 1 and 9

line to the eastern portion of the WTC site. A west entrance/exit would direct passengers beneath Route 9A toward BPC and the World Financial Center.

The concourse consists of a main level and a balcony. The concourse's main level would connect to the mezzanine's east and west entrances/exits via escalators and elevators and would provide connections to offices and retail on the WTC site, FSTC's Dey Street Underpass, and the World Financial Center via a new underpass beneath Route 9A. The balcony level would provide connections to MTA/NYCT's Cortlandt Street (1 and 9), Cortlandt Street (R and W), and WTC (E) subway stations.

The street-level, terminal building, would be constructed on the eastern portion of the WTC site along Church Street near its intersections with Dey and Fulton Streets. It would provide access from Church Street and proposed elements of the WTC Memorial and Redevelopment Plan, including Greenwich Street and a public plaza. The building would also provide for natural light to the concourse level.

Prior to September 11, 2001, PATH had two ventilation structures within the median of Route 9A, which were used for both smoke evacuation and piston relief. These vent structures were located immediately above the PATH tunnels and contained evacuation stairs for emergency egress. As part of their program to enhance security within and around the WTC site, PANYNJ plans to reconstruct the ventilation structures to be 40 feet tall. Ideally, the future vents would serve the combined purpose of piston relief, smoke evacuation, and emergency egress. PANYNJ would construct the new ventilation structure in nearly the same location as before September 11, 2001.

NYSDOT is currently evaluating its plans for the reconstruction of Route 9A. Although PANYNJ prefers to locate the PATH vents in the future Route 9A median, it may be necessary to seek other locations (i.e., within the future Memorial Center or west of Route 9A) if NYSDOT cannot accommodate the vents as part of the ultimate design of the roadway. This FEIS identifies the Route 9A median as the Preferred Alternative for the ventilation structures. However, if the future plans for the Route 9A Project mandate an alternative location for the vents, FTA and PANYNJ would assess the alternative location through the appropriate NEPA process.

In addition to the emergency egress that would be provided via the vent structures, PANYNJ would construct emergency egress from the Terminal's track/platform and mezzanine levels. Egress stairways would be located near the north and south ends of the Terminal and would provide emergency access to Greenwich Street. The Permanent WTC PATH Terminal would share its emergency egress with the other facilities on the WTC site. PANYNJ plans to collocate one of these stairways within the proposed Performing Arts Center in the site's northwest quadrant and the other in the southwest quadrant within a museum or building that would be part of the WTC Memorial.

PANYNJ would reinforce the roof of the Terminal's east-west pedestrian concourse. The roof of the Terminal's east-west concourse would also serve as the road bed for the future extension of Fulton Street between Route 9A and Greenwich Street. The reinforced roof would consist of hardened, reinforced concrete to enhance the security of the east-west concourse below. The actual paving, landscaping, and opening of Fulton Street would be undertaken as a separate action.

The Preferred Alternative includes funds for the reinforcement of the basement walls, which form the "bathtub" within the WTC site. This work is necessary to ensure the structural integrity

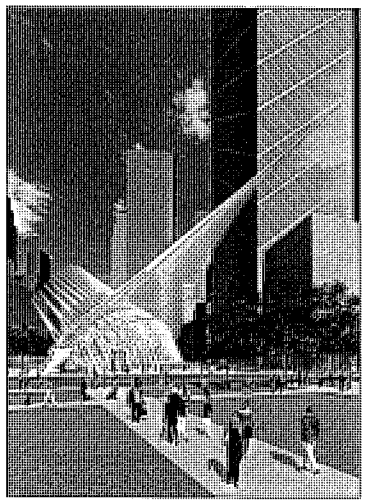
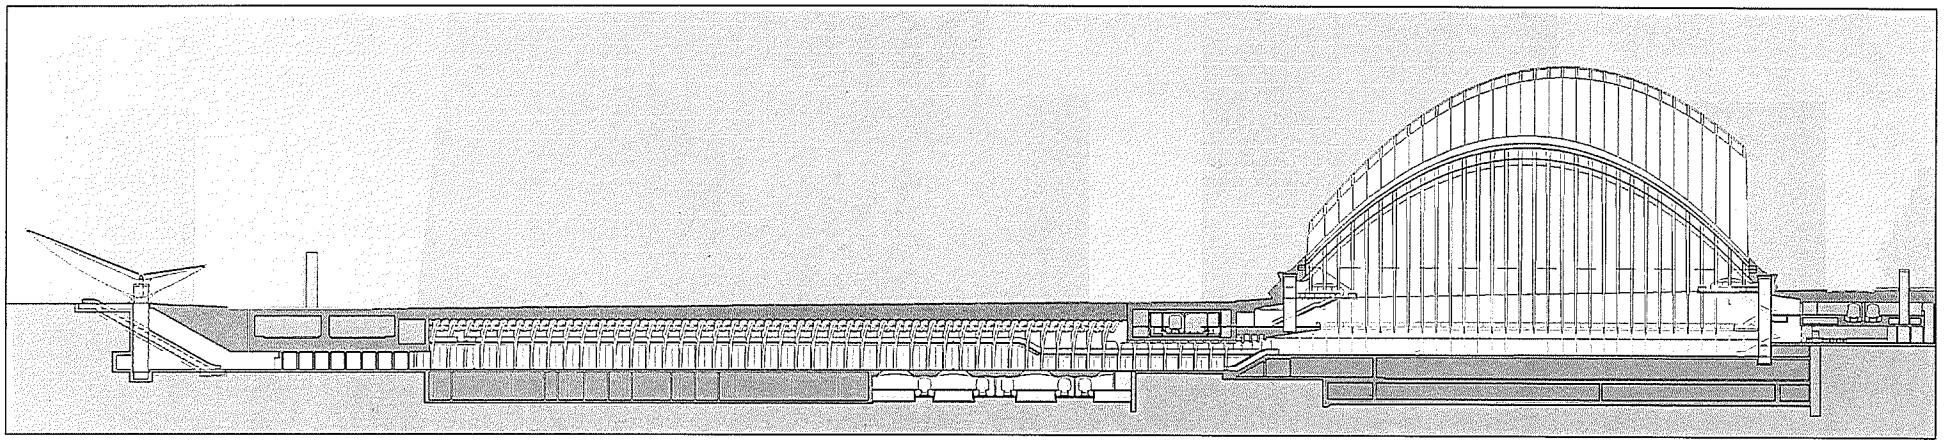
Concourse Level



Street Level



Elevation

PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure S-2
Proposed Terminal Plan

of the walls and to support future redevelopment of the WTC site, including the Permanent WTC PATH Terminal. As part of the Permanent WTC PATH Terminal's construction, PANYNJ could reinforce the entire west bathtub wall except for portions that would remain visible as part of the WTC Memorial. PANYNJ would also reinforce portions of the east bathtub wall abutting MTA/NYCT's 1 and 9 line that were not previously reinforced. If other development on the WTC site does not move forward according to current schedules or plans, it may also be necessary to reinforce portions of the north bathtub wall east of Freedom Tower and portions of the south bathtub wall above the existing PATH substation.

Construction of the Terminal may also require the demolition and excavation of remaining structures within the eastern portion of the WTC site between MTA/NYCT's 1 and 9 line and Church Street, which includes all portions of the former H&M Terminal. This work would also support the future development of the site by others.

The DEIS noted that the removal of portions of the northwest remnant sub-grade structures on the WTC site may be undertaken as part of the Terminal's construction. However, subsequent to the publication of the DEIS, the removal of the northwest remnant sub-grade structures have been undertaken as an independent action pursuant to the stipulations of the Programmatic Agreement prepared for the WTC Memorial and Redevelopment Plan.

SUSTAINABLE DESIGN COMMITMENTS

As part of the construction and design of the Permanent WTC PATH Terminal, PANYNJ would implement Environmental Performance Commitments (EPCs). These EPCs were developed through a cooperative effort of the various project sponsors of the Lower Manhattan recovery effort. Divided into six resource areas, the EPCs are intended to reduce both short-term (construction) and long-term (operational) impacts to the environment. PANYNJ would implement the EPCs through specific actions identified in its public involvement and governmental entities coordination plan, construction environmental protection plan, design documents, and contracts. The specific EPCs and strategies for their implementation are described in Table S-5 and Section E below.

Per the guidance of the EPCs, the Terminal's design would incorporate sustainable/"green" design guidelines. PANYNJ is studying measures for the Terminal's initial design which are organized into six component areas: urban considerations, site, water, energy, materials, and indoor environment. These guidelines, which are consistent with industry standards, promote the use of techniques to reduce the demand for resources while promoting the capture and reuse of energy and materials, whenever possible. These measures would include the use of natural lighting, energy-efficient design, and renewable energy sources for heating and cooling.

One of the major sustainable/"green" design guidelines developed for the Permanent WTC PATH Terminal is the ability to use river water for cooling the Terminal's heating, ventilation, and air conditioning (HVAC) system. River water cooling was used prior to September 11, 2001 and its reuse is an economical and energy-efficient method to provide cooling for the components of the Permanent WTC PATH Terminal. The system's intakes, pumps, outfalls, and associated pipelines remain largely intact; river water provides lower supply temperature than other alternatives, resulting in greater energy efficiency; and river water cooling reduces the demand on the city's infrastructure. PANYNJ has filed an application with the New York State Department of Environmental Conservation to renew the State Pollution Discharge Elimination System (SPDES) permit for the WTC's river water cooling system. This application is being reviewed under an independent action.

CONSTRUCTION METHODS, SCHEDULE, AND COST

As shown in Figure S-3, the construction would begin in 2005. The Terminal would be completed in phases with an initial opening in 2009 and full completion in 2010.

The construction of the Permanent WTC PATH Terminal is comprised of five major elements as described below.

- North/South Temporary Access: Beginning in late 2005, PANYNJ would construct temporary access to the temporary WTC PATH station. Temporary access would be located on Vesey and/or Liberty Streets and would allow for the continued use of the temporary station as construction of the Permanent Terminal proceeds. The temporary access points would be maintained until the Terminal Hall and other street-level access can be provided. The duration for the construction of this element is 15 months.

- East-West Concourse: During this phase, PANYNJ would construct the east-west pedestrian connection through the WTC site and beneath Route 9A as well as the headhouse adjacent to the World Financial Center. If NYSDOT pursues a short-bypass alternative for the Route 9A Project, then they would construct the east-west concourse in tandem with their construction of the roadway tunnels. If NYSDOT pursues an at-grade alternative for Route 9A, then the east-west concourse would be constructed at nearly the same elevation by PANYNJ; however, the concourse would be mined with spoils removed from within the WTC site or from a shaft near the World Financial Center that would eventually provide the vertical connection between the concourse and the street-level headhouse. Following the completion of the east-west concourse through the WTC site, PANYNJ would harden its roof, which would eventually become the road bed of Fulton Street between Route 9A and Greenwich Street. The hardening of roof would involve the laying and reinforcement of high density concrete. Upon completion, the hardened road bed would serve as staging for the construction of Freedom Tower, which is being undertaken independent of the Preferred Alternative. The full duration for the east-west concourse construction is 36 months.

- Platform D, Arch Columns, and Temporary Underpinning: This element of construction involves the preparation work needed to maintain PATH operations as components of the Permanent Terminal are construction. It includes the laying of a temporary Track 6 and the permanent Platform D within the WTC "bathtub." The temporary track is needed to allow for continuous PATH operations as other tracks are reconfigured for use in the Permanent Terminal. Platform D provides access to trains using Track 6 and is, therefore, the first permanent platform to be constructed. Track 6 would be removed once PATH service can be fully restored on Tracks 1 through 5. During this phase of construction, the column supports for the Terminal's arches would be placed. Also, temporary underpinning of the 1 and 9 Line would be undertaken to support the later widening of the passageway between the mezzanine level and the concourse level. The total duration of this element is 20 months.

- Permanent Platforms, Tracks, and Mezzanine: This component of construction includes the major structural and finishing work for the platform and mezzanine levels of the Terminal. It includes placement of the structural arches, mezzanine construction, the underpinning of the 1 and 9 Line and construction of the passageway between the mezzanine and concourse levels, the lengthening and upgrade of Platforms A, B, and C, the completion of Platform D, and the construction of PATH's ventilation structures in the median of Route 9A. Grouting beneath the existing 1 and 9 subway tunnel would be performed from within this tunnel to protect the existing subway tunnel from the subsequent excavation work. Grouting is used in

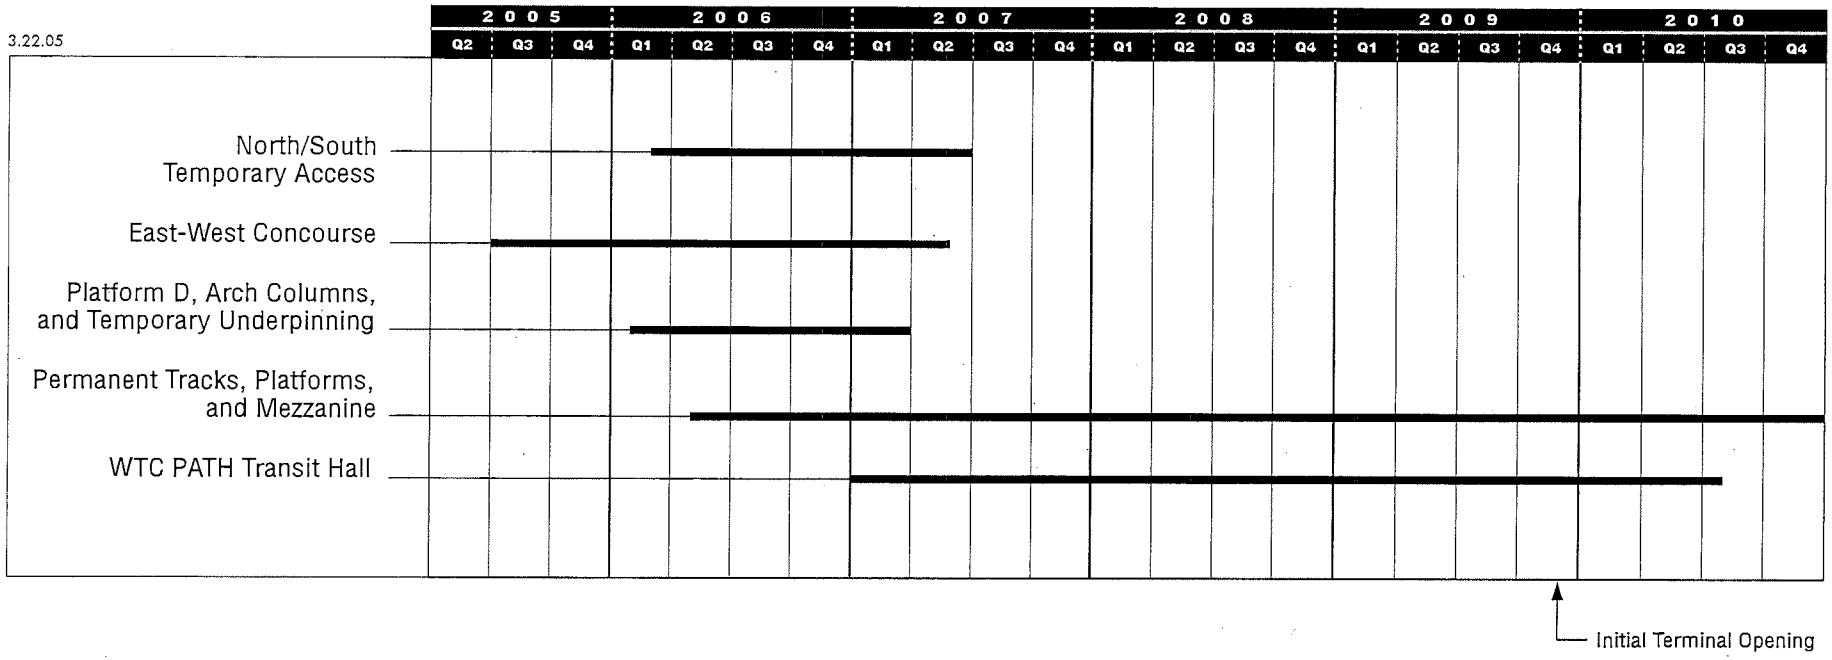


Figure S-3
Construction Schedule

soft soil to stabilize surrounding soils as a tunnel is excavated. In this case, a machine would be used to stabilize the surrounding soils by injecting cement or a similar material to form a hard tunnel shell. It would involve the use of compressed air operated drill rigs and grout pumps. Excavation and tunneling beneath the subway would occur from the west bathtub and proceed east. Tunneling would be accomplished via conventional mining techniques (e.g., shield with hand or mechanical excavation) and would require removal of existing piling supporting the subway tunnel and replacement with new piles/foundations. Spoils would be removed via the existing ramp to Liberty Street or by lifting to the surface with a crane and skip box. Demolition of temporary and construction of the permanent tracks, platforms, and mezzanine would occur alternating between northern and southern portions of track, platform, and mezzanines. To maintain train service and passenger safety and access, only one half (either the northern or southern half) of the platform would be demolished and converted, then the second half would follow. This stage of activity would continue until all tracks and platforms are converted. All work would occur within the west bathtub of the WTC site with access from the existing ramp from Liberty Street. No street closings are anticipated for this work to take place. The Terminal's two ventilation structures with emergency egress would be constructed within the median of Route 9A, and would also involve the installation of fans. The total duration for this phase of construction is 45 months.

- WTC PATH Transit Hall: This element consists of construction of the PATH terminal building, which includes the construction of all sub-grade and above-grade levels, the north-south pedestrian concourse, and the Terminal's mechanical and support systems. A preliminary estimate for the duration for the construction of the building area is 42 months, from late 2006 through early 2010. Lane closings on Church Street may be required for materials delivery and for the erection of pre-fabricated trusses and for the structural steel framing.

Construction workers and supervisors would arrive on site in personal vehicles or via mass transit. Limited parking would be available on-site and would primarily be used by supervisors arriving in light trucks. Heavy and light trucks would be present during demolition and construction stages throughout all elements; however, the number and type of trucks would vary between elements.

Generally, the hours of construction would be Monday through Saturday from 7 AM to 6 PM in one 10-hour shift. A 10-hour work shift was assumed not only for the construction of the Permanent WTC PATH Terminal but was also assumed for the analyses being prepared for the other Lower Manhattan recovery efforts. The proposed hours of construction are consistent with New York City construction guidelines and allow for a consistent basis to assess cumulative effects for the Lower Manhattan recovery efforts. However, in some cases, it may be necessary to conduct construction activities at night, particularly when temporary lane closures would be needed or to coordinate and stage activities for the daytime shift. These nighttime activities would be limited throughout the construction period and would have fewer staff than the daytime shift. These nighttime activities would be required to meet the New York City Noise Control Code (NYC Administrative Code Title 24 §201 et seq.), which does not allow for activities and equipment that would exceed specific noise criteria.

The vehicles, primarily trucks, needed to deliver materials for construction activities and remove demolition debris would be required to adhere to established site ingress and egress truck routes.

For access to the site, trucks arriving and departing would use Route 9A, Broadway, Liberty Street, Church Street, and Barclay Street.

The Preferred Alternative would cost $2.138 billion. A total of $1.750 billion would be funded by the FTA through the Lower Manhattan Transportation Recovery Effort. The remaining $388 million would be funded by PANYNJ through their capital improvements budget.

D. ANALYSIS FRAMEWORK

To assess the potential impacts of the Project Alternatives, this EIS considers three analysis years—construction period, opening year (2009), and design year (2025). Given the unique circumstances leading to the need for and implementation of the Project Alternatives, this EIS considers potential environmental impacts as they relate to two baseline conditions—pre-September 11, 2001 and post-September 11, 2001. Furthermore, a more detailed evaluation of potential cumulative effects was prepared than is typically undertaken.

BASELINE CONDITIONS

To fully investigate the potential impacts, this EIS considers two baseline conditions to formulate future scenarios for the Project Alternatives.

Pre-September 11, 2001 Baseline

The pre-September 11, 2001 baseline condition reflects the built environment in Lower Manhattan prior to the terrorist attacks. The pre-September 11, 2001 baseline is used for the evaluation of potential future long-term environmental impacts and for the preparation of appropriate mitigation measures.

Because the terrorist attacks resulted in drastic differences in the physical and social characteristics of Lower Manhattan, the current environment in Lower Manhattan does not reflect the level of activity that existed prior to September 11, 2001. The planned redevelopment of Lower Manhattan would result in the replacement of much of the real estate and infrastructure that was lost, resulting in increased trips to the area. However, it is anticipated that the environment in the vicinity of the Permanent WTC PATH Terminal could continue to support the level of activity that existed before September 11, 2001. Therefore, the quantified analysis of future impacts and mitigation is based on a theoretical comparison that assumes the terrorist attacks had not occurred, in order to evaluate the future condition when Lower Manhattan has truly recovered and continues to grow.

The pre-September 11, 2001 baseline condition precludes the federally sponsored redevelopment and recovery projects in Lower Manhattan since it is assumed that the terrorist attacks had not occurred. Therefore, the future conditions developed based on the pre-September 11, 2001 baseline does not include the following projects: WTC Memorial and Redevelopment Plan; Route 9A; Fulton Street Transit Center; and South Ferry Terminal.

However, other real estate development is assumed to have been constructed whether or not the terrorist attacks had occurred. These projects, therefore, are accounted for in the future conditions based on the pre-September 11, 2001 baseline.

Post-September 11, 2001 Baseline

The post-September 11, 2001 baseline condition reflects the current environment in Lower Manhattan. This scenario considers the loss of the WTC and transportation infrastructure as well as changes in employment and land use resulting from the terrorist attacks.

Because the revitalization of Lower Manhattan would take more than a decade, the post-September 11, 2001 baseline condition is used to project future conditions in the interim (construction period and opening year) analysis years presented in this EIS. It also considers the numerous projects planned for the redevelopment of Lower Manhattan, including the $4.55 billion transportation recovery projects. In addition, this scenario is applied to the design year conditions without PATH service under the No Action Alternative, since the other recovery efforts would be pursued independently.

CONSTRUCTION ANALYSIS FRAMEWORK

The DEIS presented a construction schedule and phasing plan developed in October 2003. This plan was prepared in a coordinated effort to support the assessment of cumulative effects for the Lower Manhattan recovery projects. The phasing plan presented in the DEIS consisted of 6 Elements as follows:

- Element 1: Permanent Tracks, Platform Conversion, Mezzanine, and Concourse Construction;
- Element 2: Tunnels under 1 and 9 Line;
- Element 3: Route 9A Connection;
- Element 4: Liberty Plaza Connection;
- Element 5: Excavation/Deconstruction of the temporary PATH station; and
- Element 6: PATH Terminal Building.

Since the Liberty Plaza Connection is not being proposed as part of the Preferred Alternative, Element 4 of the DEIS phasing plan has been eliminated in this FEIS. Furthermore, since publication of the DEIS, project engineering and design have progressed allowing for a more refined assessment of the construction schedule and phasing.

The analysis in the DEIS assumed construction would begin in the first quarter of 2005, but it is now anticipated to start in the third quarter of 2005. Furthermore, the DEIS analysis of construction impacts assumed a more fast-tracked approach with the majority of activities occurring in 2006. Based on current engineering data, design considerations, and coordination issues with other separate undertakings on the WTC site, the construction activities would be more evenly distributed through 2006, 2007, and 2008. Since the analysis in the DEIS was based on a higher level of activity than is currently proposed, the corresponding construction-related impacts are higher than what is now expected. Assumptions in the DEIS regarding construction scheduling and phasing have not been revised for the FEIS, as they represent the maximum predicted truck trip generation, noise levels, and pollutant concentrations that could possibly occur under the most aggressive construction schedule. Mitigation measures developed with respect to these maximum predicted levels would be even more effective under the currently proposed, less aggressive construction schedule.

This construction analysis framework in the DEIS considered the peak period of activity when four elements of the Terminal would be in simultaneous construction, including the Liberty

Plaza Connection. Elements 1, 2, and 3 of this framework were not changed for the quantified construction-period analysis presented in this FEIS; however, Element 4, the Liberty Plaza Connection, was dropped since it is no longer considered as part of the Preferred Alternative.

The following briefly describes the activities included in Elements 1, 2, and 3 of the construction analysis framework.

- Element 1, Permanent Tracks, Platform Conversion, Mezzanine and Concourse Construction, consists of three seven-month stages over a total duration of 21 months. In each stage, one existing platform/track section of the temporary WTC PATH station would be demolished and reconstructed with new mezzanine/concourse connections. All work would occur within the west bathtub of the WTC site with access from the existing ramp from Liberty Street. No street closings were anticipated for this work to take place.
- Element 2, Tunnels under 1 and 9 line, would involve the driving of the mezzanine and concourse tunnels under MTA/NYCT's 1 and 9 subway line beneath Greenwich Street. The work would take place from within the existing subway tunnel and from within the existing west bathtub. The work would involve underpinning the subway tunnel followed by the excavation and construction of the underpasses. Estimated duration of tunnel driving and construction is 20 months. Tunneling would be accomplished via conventional mining techniques (e.g., shield with hand or mechanical excavation). Over the 20-month period, construction activities including spoil removal, grout injection, underpinning, concrete pouring, and steel installation would occur. During this period, it may be necessary to occasionally suspend 1 and 9 train service through the construction zone during off-peak periods. This work would be coordinated with MTA/NYCT to minimize potential disruption to commuters.
- Element 3, Route 9A Connection, would include construction of the concourse under Route 9A, which would be constructed near the northwest corner of the site. Slurry wall construction and cut and cover excavation would be employed to cross Route 9A. The estimated duration was approximately 15 months. This work would be coordinated with NYSDOT's proposed reconstruction of Route 9A.

Table S-1 shows the on-site equipment requirements in the peak construction year for Elements 1, 2, and 3. Table S-2 presents the daily delivery trips for each of these elements.

The Preferred Alternative would generate 294 daily vehicle trips during construction. Of these, 236 trips would be delivery and service trucks traveling to and from the site, and a total of 58 daily trips would be construction workers arriving in their personal automobiles.

APPROACH TO CUMULATIVE EFFECTS

The Permanent WTC PATH Terminal is part of a larger redevelopment plan for Lower Manhattan that includes transportation and development projects being sponsored by both public and private groups. Although funded and planned separately, these projects would have a cumulative effect on the character and quality of Lower Manhattan and the region as a whole both during and after construction. To guide the Lower Manhattan project sponsors in their analysis of cumulative effects under NEPA, FTA prepared its *Approach to Cumulative Effects Analysis for the Lower Manhattan Recovery Effort* (July 2003). The approach described in FTA's guidance ensures consistency between the federally-sponsored projects through a coordinated set of analysis assumptions and methodologies for all of the transportation recovery

Table S-1
Construction Analysis Framework – Summary of On-Site Construction Equipment in the Critical Analysis Year

Equipment	Element 1	Element 2	Element 3	Total
Air Compressor for Impact Wrenches	2	0	0	2
Air Compressor for Pavement Breakers	1	0	0	1
Air Operated Grout Drills	0	2	3	5
Backhoe	0	0	1	1
Crawler Crane	1	1	1	3
Hi-Lift (forklift)	2	2	2	6
Hydraulic All-terrain Crane	1	0	0	1
Hydraulic Excavator with Hoe Ram	1	0	0	1
Hydraulic Excavator with Thumb	1	0	0	1
Impact Wrenches	20	0	0	20
Pavement Breakers	4	0	1	5
Welding Machines	2	1	2	5

Table S-2
Construction Analysis Framework – Summary of Peak Daily Off-Site Vehicle Trips in the Critical Analysis Year

Type	Element 1	Element 2	Element 3	Total
Heavy Trucks	132	22	20	174
Light Trucks	42	10	10	62
Private Vehicles	34	12	12	58
Total	208	44	42	294

projects. As individual projects advance through the NEPA process, the analysis and any identified impacts are incorporated into the documentation of later projects to ensure a consistent, up-to-date, and comprehensive evaluation of potential cumulative effects.

The study of cumulative impacts focuses on subject areas most prone to potential cumulative adverse effects. The federal partners and local project sponsors identified five areas with the highest potential for cumulative effects—access and circulation; air quality; noise and vibration; cultural and historic resources; and economic factors. The local project sponsors have coordinated amongst themselves and with federal agencies to develop consistent methodologies, assumptions, data sources, and impact criteria for the evaluation of impacts for the five cumulative effects subject areas. Furthermore, the project sponsors agreed to a consistent set of EPCs for these resource areas to be implemented as part of their projects in order to minimize or avert adverse impacts.

The cumulative effects analysis considers both the potential short-term (construction period) and long-term (operational period) beneficial and adverse impacts. For short-term, construction period assessment, the analysis explicitly considers the cumulative effects of the five federally-funded Lower Manhattan Recovery Projects—Permanent WTC PATH Terminal, WTC

Memorial and Redevelopment Plan, Fulton Street Transit Center, South Ferry Terminal, and the Route 9A Project (see Figure S-4). Other privately-funded initiatives were considered but were not explicitly modeled. These projects were either too small to influence the outcome or were considered as part of the baseline from which cumulative effects were projected.

Since publication of the DEIS, the construction schedules for the WTC Memorial and Redevelopment Plan and the Route 9A Project have been delayed by approximately one year, and as described above, the schedule for the Permanent WTC PATH Terminal is also changed. Although, the peak activity levels for these three projects is expected to be similar to the analysis presented in the DEIS, the actual peak period is more likely to occur in 2007 and/or 2008 rather than in 2006. The construction schedules for the South Ferry Terminal and the Fulton Street Transit Center are similar to those presented in the DEIS, meaning that activities for these projects would peak in 2006. Although the Fulton Street Transit Center and South Ferry Terminal projects would have less overlap with construction of the Permanent WTC PATH Terminal, the peak daily equipment and truck activities for these projects were not changed in this FEIS. Thus, the cumulative effects analysis presented herewith is a conservative baseline for the development of mitigation measures since a lower level of activity is more likely to occur in the peak construction year for the Permanent WTC PATH Terminal.

E. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

ANALYSIS RESULTS

Summarized in this section are the findings of the environmental analyses performed for this FEIS. Analyses were performed to determine the potential for adverse and/or beneficial impacts in the following categories: land use, neighborhood character, and social conditions; economic conditions; visual and aesthetic considerations; historic resources; archeological resources; transportation; air quality; noise and vibration; energy; contaminated materials; water resources; wetland and terrestrial resources; and coastal zone management. Table S-3 provides a summary of the potential impacts during the construction period, while Table S-4 provides a summary of design year impacts. Where the potential for adverse impacts have been identified and mitigation measures are feasible, such measures are discussed below.

As described above, this EIS considers a 2009 opening year. The opening year analysis accounts for the continued operation of a temporary WTC PATH station, which is assumed to be closed by 2025. Furthermore, the redevelopment of the WTC site and the construction of several other private development projects in Lower Manhattan would not be fully completed in 2009 but would be achieved before 2025; therefore, there would be fewer trips to Lower Manhattan in the opening year than in the design year. Given these differences in the opening year and design year conditions, the 2009 analysis shows less pronounced benefits of a Permanent WTC PATH Terminal over the No Action condition than is reflected in 2025. However, in terms of the Terminal's potential impacts to cultural resources, noise and vibration, natural resources, and pedestrian circulation, the impacts in both 2009 and 2025 are nearly identical. Thus, the mitigation measures described below for the 2025 design year would also apply to the 2009 opening year.

MITIGATION

As described in Table S-3, the Preferred Alternative would result in impacts to cultural resources, vehicular traffic, air quality, noise and vibration, and contaminated materials during

3.31.05

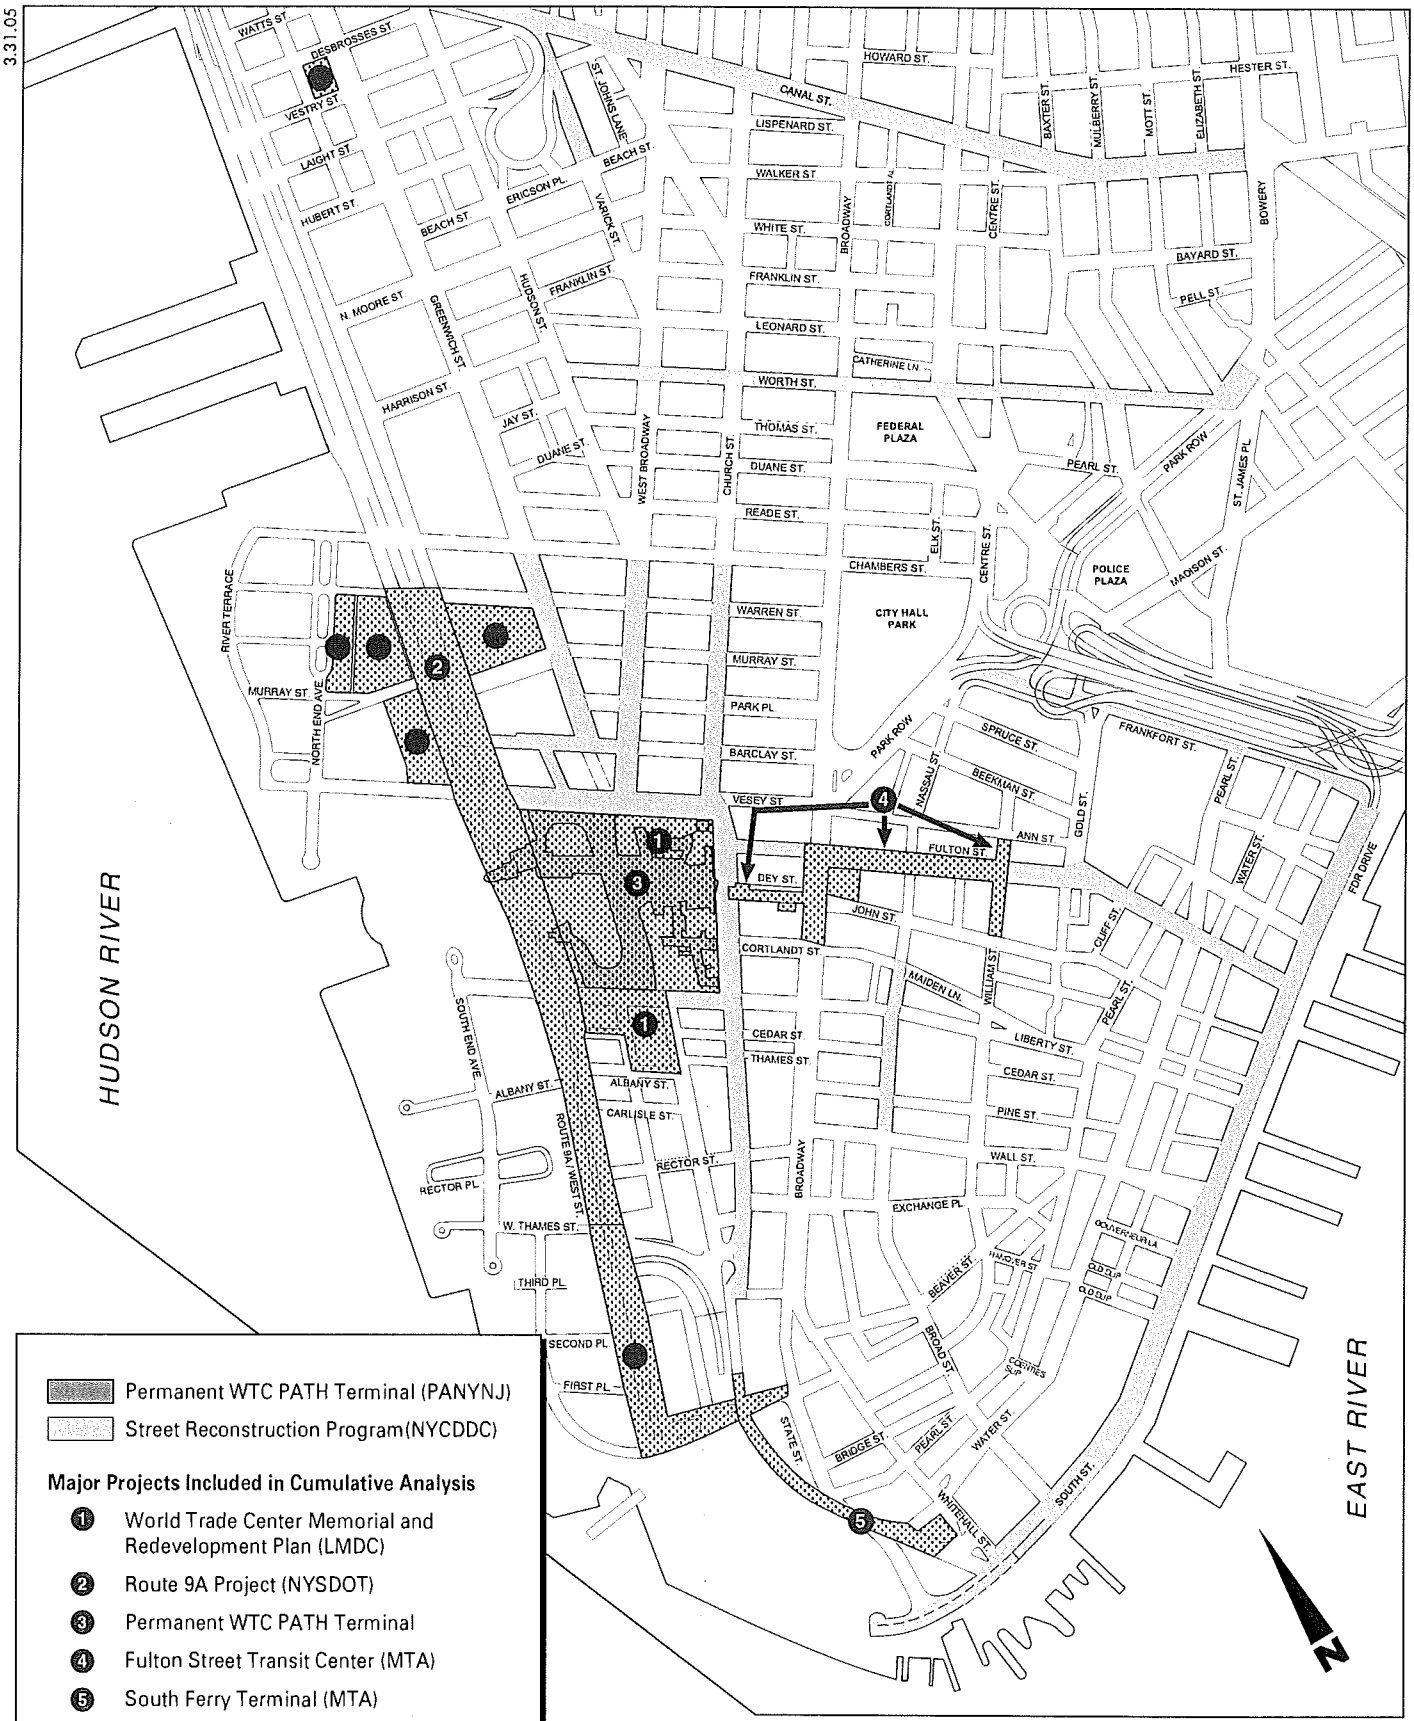

Figure S-4

Lower Manhattan Projects Planned for Construction in the Critical Analysis Year

the construction period. PANYNJ would implement Environmental Performance Commitments (EPCs) as part of the project to minimize or avoid adverse impacts during construction (see Appendix I). Although the EPCs would avert many of the adverse impacts identified in the FEIS, additional mitigation would be necessary. Table S-5 describes the EPCs and plans for their implementation, while the additional project-specific mitigation commitments are shown in Table S-6.

Generally, the Preferred Alternative would have greater environmental benefits than the No Action Alternative over the long-term, operational period. However, the analysis showed that the Preferred Alternative would result in adverse effects to cultural resources, on-street pedestrian circulation, noise and vibration, and natural resources (see Table S-4). Mitigation measures have been recommended to minimize these adverse impacts as shown in Table S-7.

The EPCs described in Table S-5 were developed through a coordinated effort of the Lower Manhattan project sponsors and are contained in a letter signed in September 2003 (see Appendix I). Throughout the DEIS and FEIS phases for the Permanent WTC PATH Terminal, the project sponsors developed and implemented a framework for construction coordination, which included several working groups to address issues that have been identified in the individual environmental documents and to further refine the EPCs. The sponsors established a Schedule Working Group, a Logistics Working Group, a Traffic Working Group, and a Standards Working Group. Through this coordinated approach to the evaluation of individual projects, the project sponsors strove to meet or exceed the EPCs and to investigate and remediate issues and concerns that could arise during the construction process.

Since the publication of the DEIS, Governor Pataki established, by way of an Executive Order, the Lower Manhattan Construction Command Center (see Appendix I). This entity will coordinate the construction of the Lower Manhattan Recovery Projects as well as any other construction projects in Lower Manhattan with a value in excess of $25 million through 2010. The Command Center will have an Executive Committee consisting of representatives from the various sponsoring agencies and other key state and local agencies. The Command Center and its Executive Committee will be managed by an Executive Director, who was appointed in February 2005.

As stated in the Executive Order, the functions of the Command Center will be:

- "Coordinating the work of the participants in the rebuilding process and ensuring that the construction in Lower Manhattan proceeds as scheduled by mediating conflicts in schedules and street and site access between construction projects, agencies, and the Lower Manhattan Community;"
- "Coordinating protocols, contract requirements and activities outside of individual project limits through planning on a daily basis throughout construction for government agencies, developers, construction managers, general contractors, and contractors;"

"Coordinating construction projects to minimize inconvenience for residents, workers, pedestrians, vehicles, and commuters;"

- "Ensuring that the Lower Manhattan area remains neat, clean and orderly throughout construction;"
- "Communicating with residents, businesses, and the general public through a communications director working with each agency's communications and public outreach

personnel; providing a central focus on issues critical to the local community and the construction industry, by coordinating initiatives, public outreach, and information;" and

- "Utilizing technology to facilitate coordination of projects."

Although the Command Center and the Lower Manhattan Construction Coordination Group will work to implement and enhance the EPCs for all of the Lower Manhattan Recovery Projects, PANYNJ will independently ensure that its EPCs are met. Coordination and circulation plans will accompany the Project's design documents, and the project's contract documents and construction specifications will include the EPCs and specific measures to monitor these commitments as construction moves forward.

Also, subsequent to publication of the DEIS, FTA and PANYNJ executed a Memorandum of Agreement (MOA) pursuant to Section 106 of the National Historic Preservation Act (see Appendix B). The MOA includes measures to avoid, minimize, or mitigate the Project's adverse impacts to historic properties both during and after construction. The MOA was developed through an extensive Section 106 consultation process that included the New York State Department of Parks, Recreation, and Historic Preservation; the U.S. Advisory Council on Historic Preservation; the New York City Landmarks Preservation Commission; and historic preservation, community, and public interest groups. The MOA establishes a process, which PANYNJ must follow as the Terminal's design moves forward. This process commits PANYNJ to incorporate certain remnants and structures on the WTC site into the Terminal's design to mitigate its adverse impacts and also includes stipulations to ensure ongoing coordination with the Section 106 consulting parties.

FTA will issue a ROD for the Permanent WTC PATH Terminal. The ROD will summarize the impacts of the Preferred Alternative and will include the mitigation commitments that would minimize or avoid these impacts. This would include the EPCs, the commitments set forth in the Project's Section 106 MOA, and all other mitigation measures identified in this FEIS.

SECTION 4(F) EVALUATION

Since the project is being funded by the FTA, an administration of the USDOT, it must comply with Section 4(f) of the USDOT Act of 1966. Under Section 4(f), the Secretary of Transportation is prohibited from approving any program or project that requires the "use" of 1) any publicly owned land in a public park, recreation area, or wildlife and waterfowl refuge of national state, or local significance, or 2) any land from a historic site of national, state, or local significance (collectively "Section 4(f) resources"), unless there is no feasible and prudent alternative to the use of such land and the project includes all possible planning to minimize harm to the resource.

With respect to the term "use", Section 4(f) considers three possible ways in which a project could involve a "use" of a resource:

- When land is permanently incorporated into a transportation facility;
- When there is a temporary occupancy of land that is adverse in terms of the statute's preservationist purpose; or,
- When there is a constructive use of land.

Constructive use occurs when the project does not directly incorporate land from a Section 4(f) resource, but the project's impacts are so severe that the protected activities, features, or attributes that qualify a resource for protection under Section 4(f) are substantially impaired.

Table S-3

Probable Impacts of the Project Alternatives—Construction Period

Resource Area		No Action Alternative	Preferred Alternative
Land Use, Neighborhood Character, and Public Policy		Under the No Action Alternative, any changes in land use and neighborhood character would be attributed to other independent actions. Because this alternative would not result in the coordinated construction of the Lower Manhattan Recovery Projects, it would be inconsistent with public policy initiatives.	Lane closures, trucking activities, and noise associated with construction may affect the quality of life for Lower Manhattan's employees, residents, and visitors; however, these disruptions would be temporary and no long-term effects to land use or neighborhood character would result.
Socioeconomic Conditions		The simultaneous construction of other independent transportation and development projects in Lower Manhattan, independent of the Project Alternatives, may have impacts to local residents and businesses. Temporary road closures, trucking activities, and construction noise may temporarily affect the quality of life for employees and residents in the vicinity of the WTC site. However, these construction activities are necessary to ensure the long-term vitality of Lower Manhattan; thus, this temporary adverse impact lends to long-term positive benefits for adjacent populations.	Construction of the Preferred Alternative would not result in residential or businesses displacement. The Maintenance and Protection of Traffic (MPT) plan would ensure that residents, employees, and visitors can access existing residences and businesses as well as the temporary WTC PATH station during the Preferred Alternative's construction. The Preferred Alternative's construction would yield a total of 19,965 person-years of employment and $3.86 billion in direct and indirect expenditures. The project would also generate nearly $50 million in tax revenues.
Cultural Resources	Historic Resources	The No Action Alternative would not directly alter or disturb historic resources within the area of potential affect. Thus, any changes to historic resources would be attributed to construction associated with other independent undertakings.	Construction of the Terminal would directly disturb or alter the Hudson River Bulkhead and remaining remnants on the WTC site. Vibrations created by project construction may adversely impact 5 historic buildings in the area of potential effect.
	Archaeological Resources	The No Action Alternative would not disturb known or suspected archaeological resources. Therefore, any potential impacts to archaeological resources would result from other independent undertakings.	Construction beneath Route 9A would have an adverse impact to the Hudson River Bulkhead, which is located beneath Route 9A. The project may also disturb as yet determined archaeological resources on the eastern portion of the WTC site; however, additional testing of these sites is recommended to determine their archaeological sensitivity.
Urban Design and Visual Resources		The temporary WTC PATH station would appear as is does today. Construction activities associated with the WTC Memorial and Redevelopment Plan would be occurring on the WTC site.	Above-grade construction of the Terminal Hall may temporarily impact streetscape features. However, the Preferred Alternative would not adversely impact visual resources and view corridors during the construction period.
Transportation	PATH	The No Action Alternative would not result in adverse impacts to PATH operations during construction. However, activities associated with other projects on the WTC site may result in off-peak and weekend service disruptions.	Construction of the Preferred Alternative would be staged to fully maintain peak period PATH service. Off-peak service disruption may be necessary for certain construction activities and in order to move equipment around the site.
	Vehicular Traffic and Parking	Because the project itself would not generate construction period vehicles, there would be no associated traffic impacts during the construction period.	Project-generated, construction period vehicle trips would result in an adverse impact at the intersection of Route 9A and Liberty Street during the PM peak hour.
	Transit	The construction of other projects (i.e. Fulton Street Transit Center, South Ferry Terminal, Route 9A, and World Trade Center Memorial and Redevelopment Plan) may result in temporary disruptions to subway and bus services during off-peak periods. However, the No Action Alternative, itself, would not adversely impact transit service during the construction period.	Construction of the Preferred Alternative would not impact access to other modes of transit in the vicinity of the WTC site. Where underpinning of MTA/NYCT's 1/9 and R/W subway lines would be required, construction would be limited to off-peak hours and would be coordinated with MTA/NYCT to minimize any potential service disruptions.
	Pedestrians	The construction of other projects (i.e. Fulton Street Transit Center, South Ferry Terminal, Route 9A, and World Trade Center Memorial and Redevelopment Plan) may result in temporary disruptions to on-street, pedestrian circulation in the vicinity of the WTC site. However, the No Action Alternative, itself, would not have adverse impacts to pedestrians during the construction period.	Pedestrian circulation in the vicinity of the project site would not change substantially as compared to the No Action Alternative since most diversions would be required for construction of other independent undertakings. The current access to the temporary WTC PATH station would be maintained until replaced by new access/egress points constructed as part of the Preferred Alternative. Sidewalks along Route 9A may be closed temporarily during construction; however, north-south pedestrian access would be maintained along the Route 9A alignment.
Air Quality		Under the No Action Alternative, emissions in the area would be highly influenced by the construction activity for the WTC Memorial and Redevelopment Plan, Route 9A Project, Fulton Street Transit Center, and other public and private development projects.	The Preferred Alternative's construction would result in increased emissions of carbon monoxide (CO), particulate matter ($PM_{2.5}$, PM_{10}), and nitrogen dioxide (NO_2) at receptor sites in close proximity to the construction zone. However, the increases in CO, PM_{10}, and NO_2 would not exceed National Ambient Air Quality Standards and, therefore, would not result in adverse impacts. However, the maximum increase in 24-hour $PM_{2.5}$ concentrations of 47.8 $\mu g/m^2$ would be substantial. These increased emissions would generally be highest in the vicinity of the Route 9A connection, but at distances in excess of a few hundred feet from the construction zone increases in project-generated emissions would not be substantial.
Noise and Vibration		Under the No Action Alternative, noise levels in the area would be highly influenced by the construction activity for the WTC Memorial and Redevelopment Plan, Route 9A Project, Fulton Street Transit Center, and other public and private development projects.	Construction noise levels would exceed FTA's recommended 8-hour threshold for residential uses at the Hilton Millennium Hotel and 114 Liberty Street and would exceed FTA's 8-hour and 30-day commercial land use thresholds at the World Financial Center. Vibrations created by project construction may adversely impact 5 historic buildings within 90 feet of the construction zone. Farther than approximately one to two blocks from the construction zone, noise and vibration increases from the Preferred Alternative's construction are not expected to be substantial.
Infrastructure and Energy		Under the No Action Alternative, any potential impacts to infrastructure or energy during the construction period would be attributed to other independent actions.	Energy needed to construct the Preferred Alternative would be supplied by the City's power grid or on-site generators. However, this energy demand is not anticipated to adversely impact the supply of utilities to Lower Manhattan. The Terminal's construction has the potential for conflicts with existing utility lines along Church Street. Where utility lines would interfere with permanent elements of the Terminal, they would be permanently relocated. Where construction activities have a high potential to disrupt utility lines, shoring or temporary relocation may be undertaken.
Contaminated Materials		Under the No Action Alternative, any potential impacts from contaminated materials during the construction period would be attributed to other independent actions.	The Terminal's platform, mezzanine, and portions of its concourse would be within the portion of the WTC site that was fully cleared of contaminants as part of the post-September 11, 2001 recovery efforts. Although some soils remain near PATH's tunnel projections, the top 18 inches were previously removed and replaced with clean fill. Portions of the WTC site east of the 1 and 9 line have the potential for residual contamination since debris and structures remain in this area. Excavation and tunneling activities beneath Route 9A has the potential to encounter fill materials with elevated levels of polycyclic aromatic hydrocarbons (PAHs) and metals, which is typical of fill soils in New York City. During the Preferred Alternative's construction, PANYNJ and LMDC would repair damaged portions of the WTC basement wall, which would essentially eliminate the invasion of overburden ground water through the wall into the WTC site.
Natural and Water Resources		Under the No Action Alternative, any potential impacts to natural resources and water quality during the construction period would be attributed to other independent actions.	The Terminal's construction is not expected to result in adverse impacts to terrestrial or aquatic species. Furthermore, floodplain control and stormwater management techniques that would be implemented as part of the project would avert any adverse impacts to water quality during construction.

Table S-4
Probable Impacts of the Project Alternatives—Design Year

Resource Area		No Action Alternative	Preferred Alternative
Land Use, Neighborhood Character, and Public Policy		The existing temporary WTC PATH station was constructed for use on an interim basis and would not support long-term development of the WTC site or Lower Manhattan, as a whole. The absence of a Permanent WTC PATH Terminal may reduce the desirability and marketability of those independent developments that are planned throughout the study area, including those at the WTC site itself. Existing Lower Manhattan businesses may relocate to other areas of Manhattan or leave New York City altogether. As a result, the revitalization of Lower Manhattan may not be as robust as would otherwise be expected and any benefits to neighborhood character would not be realized.	The Permanent WTC PATH Terminal is part of a major public policy initiative by federal, state, and city agencies to restore the Project Site as a functioning use and to reestablish a focal point of civic space and amenities for Lower Manhattan. PATH commuters would benefit area businesses, particularly restaurants and shops, well beyond the Project Site, improving neighborhood character. The Terminal is consistent with efforts to enhance Lower Manhattan to retain existing uses and to attract new businesses in the long term. Thus, this alternative would have beneficial effects on surrounding areas, and no adverse impacts to land use, neighborhood character, or public policy would result from this alternative.
Socioeconomic Conditions		The absence of a Permanent Terminal and possible disruption of or limitations to temporary WTC PATH service may reduce the desirability and marketability of Lower Manhattan and could lead existing Lower Manhattan businesses to relocate. Access between New Jersey and Lower Manhattan could be achieved by other modes, but these options are more time consuming, less convenient, and sometimes more expensive than direct PATH service. Thus, the No Action Alternative may have adverse effects on residents and employees and could have a lasting negative effect on its economic vitality.	The Preferred Alternative would not include residential or office uses nor would this alternative have adverse direct or indirect effects to residents or businesses. While PATH ridership would increase over time, this change would have positive impacts to businesses within the vicinity of the WTC site. It is expected that any effects of the Terminal would be a positive and that there would be no adverse impacts to social or economic conditions.
Cultural Resources	Historic Resources	Since the No Action Alternative would not directly result in changes to the WTC site or adjacent properties, any contextual impacts to historic resources would be the result of other independent actions.	The area of potential effect is composed of historic structures near more modern structures, such that many older buildings are immediately adjacent to contemporary glass and metal structures. Thus, the modern design of the terminal, including its ventilation structures and World Financial Center entrance, is not expected to result in adverse contextual effects to historic resources within the area of potential effect. FTA and PANYNJ have executed a Memorandum of Agreement (MOA) pursuant to Section 106 of the National Historic Preservation Act. Per the stipulations of the MOA, the Terminal would incorporate architectural treatments and other measures to minimize and/or mitigate the Project's long-term use of remaining remnants and structures on the WTC site.
	Archaeological Resources	Since the No Action Alternative would not have resulted in construction in areas with known or potential archaeological sensitivity, there would be no adverse impacts to archaeological resources.	Adverse effects to the Hudson River Bulkhead beneath Route 9A and potential adverse effects to potentially sensitive areas on the WTC site would be resolved during the construction period in consultation with SHPO. Thus, this alternative would not have adverse impacts to archaeological resources during the operation of the Permanent WTC PATH Terminal.
Urban Design and Visual Resources		It is assumed that infrastructure associated with the temporary WTC PATH station would be retained on the WTC site although certain alterations may be required to maintain PATH service to the extent possible. It is not expected that the No Action Alternative would have adverse effects to visual resources.	The Terminal's modern design would complement the structures planned for the WTC site. The terminal would likely become an important visual resource for Lower Manhattan, and would create a grand point of entry for the new transportation center. Similarly, the above-ground entrance to the Terminal from the World Financial Center would not have adverse impacts on the urban design or visual resources since it would be a modern design that complements the Winter Garden. The vent structures in the median of Route 9A would not block views or view corridors. They would be clad in reflective material that would blend them with their surroundings and would be in keeping with modern buildings in the immediate area. Thus, the vent structures would not have an adverse impact on view corridors or visual resources.
Transportation	PATH	Passenger volumes would surpass the safe and efficient design capacity of the temporary WTC PATH station before 2025. To continue service, PANYNJ would implement restrictive measures to ensure safety and reliable PATH operations, such as restricted peak hour access, reduced WTC train service, or, in the worst case, full closure. These measures would fail to serve passenger demand and would have operational repercussions throughout the PATH system. Absent WTC service, some passengers would divert to PATH's Christopher Street or 9th Street stations. The estimated addition of 2,300 AM peak hour passengers at each of these stations by 2025 would adversely impact their safe and efficient operation.	The Permanent WTC PATH terminal would provide added passenger capacity that would be required given the redevelopment of the WTC site. The Permanent WTC PATH Terminal would accommodate elements that the temporary WTC PATH station could not, including pedestrian linkages to surrounding buildings, all area NYCT subways lines, and more convenient access to trans-Hudson ferries. Multiple entrances and exits would reduce walking times to access and egress the new terminal, which would lead to shorter walking distances and commute times for many users. Thus, any potential impacts of the Permanent WTC PATH Terminal to its users and to PATH operations would be beneficial.
	Vehicular Traffic and Parking	The No Action Alternative may preclude PATH service to Lower Manhattan, resulting in upwards of 1,200 peak hour vehicle trips by 2025. These additional vehicle trips would result in possible adverse impacts at key locations, such as the Holland Tunnel and Route 9A. Furthermore, increased travel delays would be expected at key Lower Manhattan locations.	The Permanent WTC PATH Terminal would reduce traffic demand as compared to the No Action Alternative. Thus, the Preferred Alternative is not anticipated to result in adverse impacts to traffic operations.
	Transit	The No Action Alternative may preclude or impede PATH service to Lower Manhattan, resulting in the diversion of up to 158,000 daily trips to other modes of transit by the 2025 design year. These diverted PATH riders would increase congestion and hinder operations for these other transit modes. Added capacity could be provided on ferry and bus routes, but these additional boats and vehicles may result in additional adverse environmental impacts. New Jersey Transit commuter trains and PATH's uptown lines would experience extreme overcrowding and may not be able to provide for adequate capacity to meet ridership demand. Thus, the No Action Alternative would have long-term adverse impacts to transit service.	The Permanent WTC PATH Terminal would provide greater passenger capacity than the temporary WTC PATH station, which would serve to alleviate crowding on complementary transit services such as trans-Hudson ferry and bus service and downtown-bound subway service from Penn Station-New York. The Permanent Terminal would provide enhanced pedestrian connections between trans-Hudson ferries, NYCT subways, and PATH, which would improve transit access to, from, and within Lower Manhattan. Thus, the impacts of this alternative are expected to be beneficial.
	Pedestrians	Under the No Action Alternative, PATH customers may be diverted to other modes, which would change patterns of on-street circulation within the vicinity of the WTC site. Furthermore, absent the sub grade transit and building connections that are proposed as part of the Terminal, substantial volumes of commuters, office workers, and others would be diverted to street level, resulting in congestion on sidewalks and at street corners and crosswalks leading to and from the WTC site. It is anticipated that the No Action Alternative would result in pedestrian levels of service that would be worse than those in the area prior to September 11, 2001.	At the intersection of Church and Liberty Streets, the Preferred Alternative would add approximately 4,490 and 2,010 new pedestrian trips in the AM and PM peak hours, respectively. These trips would be added to a pre-September 11, 2001 baseline of 8,420 and 7,050 trips in the AM and PM peak hours, respectively, and would represent more than a 50 percent increase in volumes. This increase in trips would result in level of service (LOS) F conditions for the north and west crosswalks, which may cause pedestrians to spill into the opposing traffic travel lanes during the pedestrian signal. The loss in area per person would range from 1 to 10 SFP in the crosswalks, and from 1.3 to 12.4 in the northwest corner reservoir. The northwest corner reservoir LOS F in the AM peak hour would congest pedestrian flows when pedestrians are queued to cross away from the WTC/PATH site in the west and north crosswalks, and block pedestrians crossing inbound from the northeast and southwest corners of the intersection. Pedestrians normally crossing at Church and Liberty Street may divert to the Cortlandt or Cedar Street intersections, or illegally cross Church Street between Liberty and Cortlandt Streets. Pedestrians circulating through the northwest corner reservoir during surge conditions require more physical space than could be afforded in that area, which could force pedestrians to wait on the street in Liberty or Church Street vehicular travel lanes.

Table S-4 (Continued)
Probable Impacts of the Project Alternatives—Design Year

Resource Area	No Action Alternative	Preferred Alternative
Air Quality	Air quality in Lower Manhattan would improve upon the completion of construction of the Lower Manhattan recovery efforts. However, absent a Permanent PATH Terminal, there would be an increase in air pollutant emissions from the diversion of PATH customers to vehicular modes. By 2025, upwards of 15.7 tons of VOCs, 18.0 tons of NOx, 1.5 tons of PM10, and 236.0 tons of CO would be emitted by motor vehicles destined from New Jersey to Lower Manhattan if a Permanent WTC PATH Terminal were not built and temporary service was suspended..	The Preferred Alternative would reduce motor vehicle emissions as compared to the No Action Alternative. Therefore, the Preferred Alternative would have the beneficial impacts on air quality in the New York Metropolitan Area.
Noise and Vibration	In the design year, under the No Action Alternative, noise levels in the study area would be slightly higher than with the other Project Alternatives, due to the increase in vehicular traffic (autos and buses) expected to result from a reduction in, or the elimination of, PATH service. However, this expected increase in vehicular traffic would not likely increase noise levels substantially above current conditions.	The Preferred Alternative would not result in any operational transit noise or vibration impacts for uses that currently exist on the project site. However, this alternative would exceed the FTA criteria for ground-borne noise, for the most sensitive uses defined by FTA—concert halls, TV studios, recording studios, auditoriums and theaters. These uses were conservatively used to assess potential impacts at the WTC Memorial site. However, the WTC Memorial and the Preferred Alternative are being planned and designed cooperatively to ensure that transit noise from PATH operations would not adversely impact the WTC Memorial
Infrastructure and Energy	Because the No Action Alternative may generate new vehicle trips to Lower Manhattan, there would be additional fuel consumption and energy use.	Although the Preferred Alternative would be larger than the PATH facility that existed prior to September 11, 2001, advances in building materials and systems as well as the implementation of sustainable design measures are expected to result in energy demand that would be similar to or lesser than the pre-September 11, 2001 levels of consumption.
Contaminated Materials	It is unlikely that further development efforts in surrounding areas including the WTC site would cause any contaminated materials issues at the Project Site. Any soil contamination remaining on the WTC site would have been addressed independent of this alternative. Thus, the No Action Alternative would not have adverse impacts from the generation of or exposure to contaminated materials	Any contaminated materials encountered during construction would be removed from the WTC site. PATH uses limited quantities of hazardous materials and petroleum products, but such materials would not be stored on the WTC site. PANYNJ has established standard operating procedures, which include protocols for a hazardous material or petroleum spill. Thus, this alternative would not result in adverse impacts from the exposure to or generation of contaminated materials.
Natural and Water Resources	Any adverse impacts to natural and water resources under the No Action Alternative would result from the construction or operation of independent projects on or near the WTC site. The No Action Alternative itself would not result in adverse impacts to natural and water resources.	The use of glass as the primary material for the street-level terminal has the potential to result in day-time bird strikes. However, other above-grade elements of the Terminal are not expected to result in adverse impacts to terrestrial species. Stormwater generated on-site would be pretreated and would be discharged to the City's combined sewer system. Although elements of the Terminal would be located within the floodplain, its design and operation would incorporate floodplain control devices and would comply with a New York State Department of Environmental Conservation approved State Pollution Discharge Elimination Permit. The river water cooling system includes two existing intakes located on the eastern shore of the Hudson River near the World Financial Center. The New York State Department of Environmental Conservation is currently reviewing PANYNJ's application to renew their State Pollutant Discharge Elimination System (SPDES) permit for the river water cooling system. As part of this application, PANYNJ has prepared a Best Technologies Available (BTA) study that specifies measures to protect fish eggs and larve from entrainment and entrapment associated with the systems intake grates as follows: using 3 gallons per minute (gpm)/ton chillers; variable speed pumps; and modifying the intake structure with 2 millimeter (mm) wedgewire screens to reduce the approach velocity to 0.5 feet per second (fps) with a corresponding river water flow of 120,000 gallons per minute (gpm). While some level of impact to aquatic organisms due to entrainment of fish eggs (and much smaller numbers of larvae) is unavoidable utilizing the selected design, overall aquatic impacts are materially reduced from pre-September 11, 2001 conditions. The proposed system would eliminate the potential for impingement and would reduce entrainment of yolk-sac and post-yolk sac ichthyoplankton from pre-September 11, 2001 levels by an estimated 93 percent and 97 percent, respectively. In fact, virtually all (approximately 98 percent) of the entrained organisms are eggs, which are subject to high rates of natural mortality and fecundity. By excluding life stages of entrainable organisms with higher natural survival rates, the selected design minimizes the adverse environmental impact of the cooling water intake structures. The river water cooling system would be closed-circuit such that water extracted from the Hudson River would not be mixed with potable water or stormwater as it travels through the system. Therefore, the system would not alter the composition of Hudson River water. The BTA study specifies that the maximum designed change in temperature (ΔT) of the proposed river water cooling system is 10°F. Therefore, cooling water flow discharges would not result in temperatures in excess of the 90°F criterion, since the maximum ambient surface water temperature is 80°F, which is consistent with regulations set forth in 6 NYCRR Part 704. Therefore, the cooling water discharges would have no potential impacts to water temperature and water quality within the Hudson River.
Coastal Zone Management	Because the No Action Alternative would be inconsistent with long range development plans for Lower Manhattan and because it would not improve access between the WTC site and the waterfront, it would not fully support the policies of New York City's Local Waterfront Revitalization Program.	The Preferred Alternative would comply with a New York State Department of Environmental Conservation approved State Pollution Discharge Elimination Permit as well as agreements with the State Historic Preservation Officer to minimize or avert adverse impacts to water quality; cultural resources; and visual resources within the coastal zone. Therefore, this alternative would be consistent with the policies set forth in the New York City Local Waterfront Revitalization Program.

Table S-5
Environmental Performance Commitments

Commitment	Implementation Plan
Access and Circulation	
Establish a project-specific pedestrian and vehicular maintenance and protection plan.	PANYNJ will develop a Maintenance and Protection of Traffic Plan (MPT) as part of their contract documents for the Preferred Alternative. A Construction Traffic Management Plan (TMP) will also be developed for the Lower Manhattan Recovery Projects to address these issues in a broader sense. The TMP will be coordinated by PANYNJ, LMDC, MTA, NYSDOT, NYCDOT, the Lower Manhattan Construction Command Center, and others, as appropriate, based on updated construction scheduling and staging as the designs of individual projects are advanced.
Promote public awareness through mechanisms such as: a) signage; b) telephone hotline; and c) website updates.	The TMP will have a public outreach component to communicate traffic information, lane closures, access changes, and travel advisories for the duration of project construction.
Ensure sufficient alternate street, building, and station access during construction period.	For the Preferred Alternative, the MPT Plan included in the contract documents will be used to implement this EPC. The TMP will address the access issues for the Lower Manhattan Recovery Projects by coordinating the individual MPTs required and times for specific land uses and infrastructure (i.e. bus stops, transit stations, etc.).
Regular communication with New York City Department of Transportation and participation in its construction efforts.	PANYNJ will consult with NYCDOT to develop the MPT Plan for the Preferred Alternative. NYCDOT will be active in the development, update, and implementation of the TMP for the Lower Manhattan Recovery Projects.
Air Quality	
Use ultra low sulfur diesel fuel in non–road construction equipment with engine horsepower (HP) rating of 60 HP and above.	PANYNJ has developed specifications for non–road vehicles. The Authority would collect monthly samples of the ULSD fuel to verify compliance.
Where practicable, use diesel engine retrofit technology in non–road equipment to further reduce emissions. Such technology may include Diesel Oxidation Catalyst / Diesel Particulate Filters, engine upgrades, engine replacements, or combinations of these strategies.	In its contract documents, PANYNJ will require the use of DPFs or other measures with equivalent PM removal efficiency for all non-road diesel engines of 50 horsepower or greater wherever the implementation of such a device is technically feasible. In cases where such technology is not available, the use of DOCs will be required. (In the DEIS, the EPCs previously mandated controls only for engines of 60 horsepower or greater, and did not specify DPFs.) In cases where neither technology can be used effectively and the operation cannot be performed by another engine or other means, the use of diesel engines greater than 50 horsepower would be allowed without tailpipe reduction measures. In such cases, the constructor would submit a request for an exception for review and approval by PANYNJ prior to implementation.
Limit unnecessary idling times on diesel powered engines to 3 minutes	As part of the contract specifications, the contractor would provide a Diesel Emission Mitigation (DEM) Plan for review and prior approval by the Resident Engineer (RE). The DEM Plan shall address the control of emissions from all engines and vehicles including those that are not equipped with emission control devices.
Locate diesel powered exhausts away from fresh air intakes.	As part of the DEM, the contractor, as determined by the RE will be required to ensure diesel powered engines vehicles are located away from fresh air intakes.
Control dust related to construction site through a Soil Erosion Sediment Control Plan that includes, among other things: a) spraying of a suppressing agent on dust pile (non–hazardous, biodegradable); b) containment of fugitive dust; c) adjustment for meteorological conditions as appropriate.	PANYNJ has developed specifications for dust suspension, materials handing, and wheel washing. The specifications require the contractor to submit a Dust Control Plan which would be implemented 24 hours per day 7 days per week.
Noise and Vibration	
Where practicable, schedule individual project construction activities to avoid or minimize adverse impacts.	In accordance with Governor Pataki's November 22, 2004 Executive Order, PANYNJ will coordinate the scheduling and staging of construction activities through the Lower Manhattan Construction Command Center. The Command Center will review PANYNJ's plans in conjunction with other planned activities and will recommend schedule adjustments, as appropriate.
Coordinate construction activities with projects under construction in adjacent and nearby locations to avoid or minimize impacts.	Through the ongoing coordination efforts of the LMCCG and the Command Center, adverse noise and vibration effects on sensitive receptors will be minimized through scheduling and routing of deliveries, as well as coordination of street closures and placement of truck/equipment staging areas.
Consider condition of surrounding buildings, structures, infrastructures, and utilities where appropriate.	In accordance with the Project's executed Memorandum of Agreement, PANYNJ will perform pre-construction building conditions surveys of the potentially affected historic buildings within 90 feet of the Preferred Alternative's construction zone. These efforts would be coordinated with the other appropriate Lower Manhattan project sponsors for sites that may be affected by cumulative vibration.
Prepare contingency measures in the event established limits are exceeded.	The Permanent WTC PATH Terminal construction contractor will procure the services of a qualified acoustical firm (INCE certified or licensed Professional Engineer) to assist in the implementation of a Noise Control and Abatement Plan, which will include on-site noise monitoring during construction, and implementation of mitigation measures to ensure compliance with applicable noise exposure thresholds. Vibration monitoring specifications, and corrective actions in the event threshold levels are exceeded, will be included in the Construction Protection Plan pursuant to the Stipulations of the Project's executed MOA.
Cultural and Historic Resources	
Establish coordination among projects to avoid or minimize interruption in access to cultural and historic sites.	Access to cultural sites within the APE for the Preferred Alternative will be maintained, to the maximum extent feasible given public safety considerations, as part of the Preferred Alternative's Maintenance and Protection of Traffic (MPT) Plan. The TMP for all of the Lower Manhattan Recovery Projects will also coordinate access to cultural sites.
Initiate public information and involvement outreach with sensitivity to local cultural resources.	PANYNJ has coordinated with the Section 106 consulting parties to develop and execute a Memorandum of Agreement pursuant to Section 106 of the National Historic Preservation Act. The executed Memorandum of Agreement includes stipulations for ongoing coordination and consultation as the Preferred Alternative's design and construction moves forward. Materials pertaining to the Project's effects on cultural resources will made available on the project's website in accordance with the stipulations of the executed Memorandum of Agreement.
Identify public information outlets that will receive and provide current information about access during construction.	This EPC will be implemented through the Lower Manhattan Construction Command Center pursuant to Governor Pataki's Executive Order.
Consult with SHPO and LPC regarding potentially impacted, culturally significant sites. Monitor noise and vibration during construction at such sites as appropriate.	PANYNJ has and will continue to coordinate with the ACHP, SHPO, LPC, and the Section 106 consulting parties pursuant to the stipulations of the executed Memorandum of Agreement. As specified in the executed Memorandum of Agreement, PANYNJ will consult with SHPO and LPC to develop construction protection plans to monitor fragile buildings within the Preferred Alternative's APE and to stipulate measures to avert impacts to these structures. As described in the executed Memorandum of Agreement, PANYNJ will coordinate its CPPs with LMDC, MTA/NYCT, and/or NYSDOT, as appropriate, for those structures that may be cumulatively affected by construction vibrations.
Economic Conditions	
Coordinate with LMDC, Downtown Alliance or other entities to minimize residential and retail impacts as required through: a) relocation assistance, as applicable, to persons to businesses physically displaced by the project; and b) focus on essential business and amenities to remain in Lower Manhattan.	This would be implemented as part of the project's MPT Plan and the coordinated TMP. All businesses in the affected area would be mapped, in conjunction with the MPT and construction staging plans, to determine conflicts on business access. The MPT and TMP would then identify solutions to these conflicts.
Add appropriate signage for affected businesses and amenities.	This would be implemented as part of the project's MPT Plan.

Table S-6
Mitigation Measures—Construction Period

Resource Area	Mitigation Measures
Cultural Resources	The Project's executed Memorandum of Agreement (MOA) under Section 106 of the National Historic Preservation Act stipulates measures to avoid, minimize, or mitigate the Preferred Alternative's adverse impacts during and after construction. This section presents the stipulations pertinent to the construction period for effects to the WTC site, the Hudson River Bulkhead, and potential archaeology on the eastern portion of the WTC site. Measures to avoid or mitigate potential construction vibration impacts are described below under "Noise and Vibration," the measures to mitigate long-term impacts are described in Table S-7. HISTORIC RESOURCES WTC Site Documentation: PANYNJ will document the WTC site and its historic features to Level II standards of the Historic American Buildings Survey/Historic American Engineering Record (HABS/HAER) prior to the removal or alteration of any historic features from the WTC site in connection with the undertaking of the Permanent WTC PATH Terminal. This documentation will consist of large-format, black-and-white photography of the site and its historic features as they currently exist; large-format photographic reproduction of selected existing drawings of current conditions and of pre-September 11, 2001 conditions; and a written history and description of the site and its historic features using information previously generated for the Coordinated DOE for the WTC site as well as the Permanent WTC PATH Terminal's DEIS and FEIS. PANYNJ will coordinate the photographic effort with the photographic efforts related to LMDC's fulfillment of Stipulation 1 as set forth in the April 22, 2004 Programmatic Agreement among the ACHP, LMDC, and SHPO for the WTC Memorial and Redevelopment Plan. PANYNJ will consult with SHPO and HABS/HAER to determine whether particular features warrant measured drawings, and any such drawings will be prepared by an individual with demonstrated experience in the preparation of measured drawings to HABS/HAER standards. The completed documentation will be submitted to SHPO and HABS/HAER for consideration. The large-format photographs prepared to HABS/HAER standards will consist of the views itemized in Exhibit H, "Schedule of Photographs" of the Project's MOA (see Appendix B). Tower Perimeter Column Bases: Up to 4 column bases in the North Tower could be temporarily removed by work to install other Project structures and infrastructure. Of the 4 column bases that could be affected by the Project foundation, those column bases that remain in situ undisturbed or are temporarily removed and returned to their original locations will be accessible following the completion of these foundations. Removing column bases, on either a temporary or permanent basis, will be considered only after practical engineering design options pursuant to Stipulations I., 2a and 2b, to preserve column bases in place have been exhausted. Column bases that are removed will be returned to their original locations if practical engineering design permits. Permanent removal of column bases will only take place as a last resort, and these column bases will be removed and stored in accordance with the stipulations of the MOA. The temporary PATH track (in addition to the existing 5 tracks) and associated ballast that will be installed on a temporary basis during construction of the Project tracks and platforms will be removed upon completion of the permanent tracks and platforms to re-expose the North and South Tower perimeter column remnants and portions of the North and South Tower footprints that may be covered by the temporary track and ballast. The construction fill currently on the footprints has been temporarily removed for the purposes of documentation of the footprints pursuant to Stipulation I.A. of the MOA, and will be replaced with clean rounded gravel as required after the documentation in order to protect the footprints and column remnants from ongoing construction. Further treatments may be specified in the Project's Resource Protection Plan. Steel Beams in Cross Form: PANYNJ will relocate the steel column and crossbeam mounted on a concrete pedestal and currently situated within the WTC site near Church Street in accordance with Stipulation VI of the MOA. The object will remain in the custody and control of PANYNJ pending final disposition of these artifacts in accordance with the rights of the respective owners. Resource Protection Plan for the WTC Site: PANYNJ, in consultation with SHPO and in coordination with LMDC and MTA/NYCT, as appropriate, shall develop a WTC Resource Protection Plan for the Permanent WTC PATH Terminal. The plan will be prepared to protect elements of the WTC site that are to remain in situ from inadvertent damage during the Terminal's construction. It will detail the Project's construction procedures and other construction plans for the site. It will provide for an inspection and reporting of the existing condition of elements, establish protection procedures, establish a monitoring program, and establish methods and materials to be used for any repairs. A historic architect, who meets the Secretary of the Interior's professional qualifications standards (48 FR 44716) in historic preservation, will be part of the design/construction team and will have the opportunity to review design drawing and specifications prior to construction. The plan will empower the Project's historic architect in consultation with the Chief Engineer of PANYNJ to issue "stop work" orders to prevent any unanticipated damage to historic properties. Recommencement of work will only be permitted once the Chief Engineer of PANYNJ and the historic architect are assured that appropriate modifications have been made to construction techniques to assure that no further damage will occur. PANYNJ will furnish copies of the Plan to SHPO, ACHP, and the Section 106 consulting parties for review and comment prior to its implementation. ARCHAEOLOGICAL RESOURCES In consultation with SHPO and NYSDOT, PANYNJ will develop and implement a plan to locate and identify intact portions of the Hudson River Bulkhead that will be affected by construction of the Permanent WTC PATH Terminal's east-west pedestrian connection. In the event that the intact portions of the Hudson River Bulkhead are identified, PANYNJ will, in consultation with the SHPO and NYSDOT, prepare an Archaeological Resource Treatment Plan for those portions of the Hudson River Bulkhead to be affected by the Project. The Archaeological Resource Treatment Plan will be submitted to SHPO and Section 106 consulting parties for their review and comment prior to implementation Prior to any Project-related subsurface disturbance at any of the locations that have been determined to be sensitive for historic archaeological resources, PANYNJ will, in consultation with the SHPO, and LMDC as appropriate, locate, identify, and evaluate the National Register eligibility of any archaeological resources at these locations in accordance with 36 CFR 800.4. In the event that FTA, in consultation with SHPO, determines that National Register-eligible archaeological resources will be adversely affected by construction of the Preferred Alternative, PANYNJ would, in consultation with FTA, SHPO, and LMDC as appropriate, and the Section 106 consulting parties, develop and implement an Archaeological Resource Treatment Plan for the Project. The Archaeological Resource Treatment Plan and documentation will adhere to the standards established by the Secretary of the Interior's Standards and Guidelines for Archaeology (48 FR 44716),including the standards therein for professional qualifications The plan will be submitted to SHPO and Section 106 consulting parties for their review and comment prior to implementation.
Vehicular Traffic and Parking	Project-generated vehicle trips will result in one construction period impact during the PM peak hour at the intersection of Route 9A and Liberty Street. A modest transfer of 5 seconds of green signal time from the Liberty Street approach to Route 9A will mitigate this adverse impact. NYSDOT has committed to prepare a construction-period traffic circulation plan. PANYNJ will incorporate this mitigation into the Preferred Alternative's Maintenance and Protection of Traffic (MPT) Plan and will coordinate this project-specific mitigation with NYSDOT as part of the Transportation Management Plan for the Lower Manhattan Recovery Projects.

Table S-6 (Continued)
Mitigation Measures—Construction Period

Resource Area	Mitigation Measures
Air Quality	In addition to measures identified in the original EPCs, PANYNJ would implement the following mitigation to further reduce project-generated emissions during the construction period. • Ultra Low Sulfur Diesel Fuel (ULSD): As described in the EPCs, PANYNJ would require that contractors use ULSD for all non-road vehicles that operate with diesel engines. • Electrification: PANYNJ or its contractor would develop a plan, in consultation with Con Ed, as appropriate, to disperse grid power throughout the contraction zone for the Preferred Alternative. In its contract documents, PANYNJ would require all contractors and subcontractors to use electrically powered equipment for air compressors, pumps, mixing, desanding and grout plants, welding machines, and any other diesel powered equipment that can be replaced with an electrically powered version. However, this does not apply to the east-west pedestrian concourse beneath Route 9A if the concourse is built by NYSDOT, since NYSDOT has not yet finalized what level of electrification would be possible for its projects. Given current conditions, it is expected that at lest 50 percent of the air compressors, pumps, mixing, desanding and grout plants, welding machines, and other diesel powered equipment that can be replaced with an electrically powered version would operate on electric power sources. • Advanced Reduction Technologies: In its contract documents, PANYNJ would require the use of Diesel Particle Filters (DPFs) or other measures with equivalent PM removal efficiency for all nonroad diesel engines of 50 horsepower or greater wherever the implementation of such a device is feasible. However, there may be cases where DPFs would not be feasible for safety considerations, mechanical reasons, or where the technology would not function properly. In such cases, the constructor would submit a request for an exception for review and approval by PANYNJ prior to implementation, and in these cases, DOCs may be used. Only in cases where, for technical reasons, neither DPFs or DOCs can be used effectively, and where the operation cannot be performed by another engine or other means, would the use of diesel engines greater than 50 horsepower be allowed without tailpipe reduction measures, subject to the above described approval process. • Newer Engines: In its contract documents, PANYNJ would require the use of post-1995 fuel injection engines, which meet the Tier II engine emissions standards, as defined in Title 40, Part 89.112. Exceptions will be made only for specific engines that are not yet commercially available as Tier II, and where the task cannot be reasonably accomplished using alternative engines or means which do comply with these demands. In such cases, the contractor would submit a request for an exception for review and approval by PANYNJ prior to implementation. • Diesel Emission Mitigation (DEM) Plan: PANYNJ would require contractors to prepare a DEM Plan that shall address the control of emissions from all engines and vehicles including those that are not equipped with emission control devices. As described in the EPCs, the DEM Plan would limit idling times on diesel powered engines to 3 minutes and would require that contractors locate diesel powered engines away from fresh air intakes. • Dust Control Plan: As described in the EPCs, PANYNJ would require contractors to submit a Dust Control Plan. Among other things, the plan would contain protocols and procedures for the spraying of dust piles, containment of fugitive dust, and appropriate adjustment measures to accommodate changes in meteorological conditions. • Verification: The effectiveness of measures to reduce construction period emissions depends on compliance. To that end, verification procedures would be implemented through construction specifications and contract documents. PANYNJ would verify mitigation and would identify opportunities to expand its implementation as part of its ongoing oversight and auditing of the Project's construction. Furthermore, verification procedures would be implemented in accordance with decisions of the Lower Manhattan Construction Command Center, including procedures for reporting updates to the public. • Other Emissions Reduction Technologies: PANYNJ is and will continue to investigate additional means (e.g., fuel emulsions) to reduce NOx (NO and NO2) emissions, but it is not yet known whether these measures would reduce the effectiveness of the above described mitigation. Therefore, specific means to further reduce NOx have not been identified in the mitigation plan for the Preferred Alternative at this time. If this investigation results in additional means to reduce NOx without jeopardizing the PM reduction measures and if other constraints such as technological availability are resolved, then PANYNJ would implement these additional mitigation techniques, as appropriate.
Noise and Vibration	NOISE PANYNJ will require contracts to use specific equipment during phases of construction to reduce noise levels below the FTA impact criteria. During the permanent track, platform, and mezzanine construction contractors will be required to use Impact wrenches with noise emission level of 82 dBA at 50 ft and mufflers on pavement breakers. During the construction of the east-west concourse, contractors will be required to place air operated grout drills inside acoustical enclosure. VIBRATION PANYNJ, in consultation with SHPO and Section 106 consulting parties, and in coordination with LMDC, NYSDOT, and MTA/NYCT, where appropriate, shall develop a Construction Protection Plan (CPP) for the Preferred Alternative. The CPP will set forth measures for the protection and avoidance of structural and architectural damage to the 5 historic properties within 90 feet of the construction zone. The CPP will be based on requirements in the "New York City Department of Buildings Technical Policy and Procedure Notice (PPN) #10/88" regarding procedures for the avoidance of damage to historic structures resulting from adjacent construction. The PPN defines adjacent historic structures as being contiguous or within a lateral disturbance of 90 feet from a lot under development or alteration. The CPP will describe in detail the construction procedures of the Preferred Alternative, as well as the construction procedures associated with other projects under construction in the vicinity of each of these historic properties. It will also provide for the inspecting and reporting of existing conditions at these properties, establish protection procedures, establish a monitoring program to measure vertical and lateral movement and vibration, establish and monitor construction methods to limit vibration; and establish methods and materials to be used for any repairs. The plan shall also specify the implementation of special vibration protection measures to protect these historic properties from increased vibration levels associated with construction activities. The CPP will provide for a historical architect meeting the Secretary of Interior's Standards to supervise implementation of the CPP. The CPP will empower the historical architect, in consultation with the Chief Engineer of PANYNJ to issue "stop work" orders to prevent any damage to historic properties, and any recommencement of work shall only be permitted at such time that the Chief Engineer and historical architect have assurance that the appropriate modifications have been made to the construction technique to assure that no damage will occur to historic properties.
Contaminated Materials	PANYNJ will require contractors to prepare a Health and Safety Plan (HASP) as part of contract documents and will be in conformance with the above described goals/objectives and will include elements outlined in the following framework: • Identification of potential contaminants and, as necessary, development of a soil or ground water sampling plan to determine contaminant concentrations in environmental media; • Identification of thresholds or action levels for contaminants and development of procedures for modification or cessation of work activities based on field screening result; • Worker health and safety training including the identification of a project health and safety officer who will be responsible for overall oversight and will maintain all appropriate documentation of safe working conditions and permits/approvals for the management of construction related wastes and residuals; • Development and implementation of field screening for contaminant detection and worker health and safety; • Identification of PPE to be used (worn) during specified phases of construction; • •Development and implementation of a Soil Management Plan identifying the methods to be used in handling, staging, disposal, transportation, and decontamination of equipment and personnel in accordance with local, state, and federal regulations; • Development and implementation of a Ground Water Management Plan to address dewatering actions from ground water infiltration and overland stormwater and the methods to be used in handling, staging, disposal, transportation, and decontamination of equipment and personnel in accordance with local, state, and federal regulations; • Development and implementation of a Dust Management Plan to address dust generated through excavation or general construction activities; • Development and implementation of management plans to address PCBs and asbestos; and, • Identification of proposed licensed waste haulers and disposal/recycling facilities, for the transportation and disposal/recycling of waste materials generated from the project. The project specific HASP will be in accordance with all applicable local, state, and federal regulations and will document that safe conditions relative to onsite workers and the public are maintained throughout the project.

Table S-7
Mitigation Measures—Design Year

Resource Area	Mitigation Measures
Cultural Resources	As noted in Table S-6, the Project's executed MOA includes stipulations to avoid, minimize, or mitigate the Project's long-term use of the National Register-eligible WTC site. As such, the Terminal will incorporate certain design elements to preserve or acknowledge remaining remnants and structures as follows. Tower Perimeter Column Bases: Up to a total of 5 column bases in the North Tower and up to a total of 3 column bases in the South Tower may be temporarily or permanently removed to construct PATH Platform D. Where Platform D will intersect the northeast corner of the North Tower footprint, the platform will be clear of vertical obstructions and architectural treatments will be used to symbolically represent the location of the footprint. A minimum of 5 to a maximum of 7 column bases of the east column line of the North Tower will be visible from Platform D. The viewing area will consist of a glass wall tilted inward from the platform combined with a mirrored wall to the west to provide a view of the column bases from this area of the platform. Appropriate signage, graphics, and lighting will complete the viewing area. The locations of column remnants of the South Tower that may be removed or permanently obscured by PATH platforms B, C, and D will be symbolically represented on these platforms through architectural treatments that define and differentiate the portions of the infrastructure that are within the Tower footprint areas. These treatments may include color differentiation, texture differentiation, symbolic representation of Tower perimeter column remnants, and/or an emblematic marker designating the location of the historic resource. East-West Slurry Wall: The design for the Preferred Alternative will provide visibility from within the Terminal to a portion of the east or west slurry wall if the following criteria are met: the condition of the slurry wall evokes the image now understood to represent the historic nature of the wall (e.g. tiebacks are part of the area to be exposed, tiebacks project beyond the re-stabilized slurry wall); the exposure provided will enable a view of the slurry wall that is clear, recognizable, and respectful of the slurry wall; and the exposure will not pose a safety hazard to the public from exposed finishes of the wall or its components. The design for the east-west pedestrian concourse shall include a location from which the members of the public may view a plaque and photograph of the west slurry wall. Passageway to the NYCT Subway Station (E Train): The new pedestrian connection between the Permanent WTC PATH Terminal and the MTA/NYCT WTC E Subway Station will incorporate the existing E subway entrance, in its current location, in a manner that retains existing materials and features of this entrance, including, but not limited to, the handrails, the travertine flooring, the steps and doors separating the E train from the pedestrian connection, and overhead signage, to the extent possible and in accordance with current building codes and Americans with Disabilities Act requirements. The design will include, at a minimum, a plaque identifying the historic features of the E subway entrance.
Pedestrians	At the intersection of Liberty and Church Streets, LOS F conditions will result on the northwest corner reservoir, and in the north and west crosswalks in the AM peak hour. More aggressive mitigation will be required at this location, consisting of widening crosswalks by 11 feet and sidewalks by six feet. PANYNJ will coordinate these improvements along with other crosswalk widenings in the vicinity of the WTC site with LMDC and the New York City Department of Transportation.
Noise and Vibration	PANYNJ will incorporate acoustical and vibration treatments as part of the Terminal to reduce sound levels and prevent reverberation with the WTC Memorial. Examples of acoustical treatments include absorptive acoustical panels and enclosures, acoustical louvers, dampers, silencers, absorptive duct linings and plenums, and mufflers. Examples of vibration reduction treatments being considered for the PATH tracks include use of resilient fasteners, ballast mats, resiliently supported ties, and floating slabs.
Natural and Water Resources	TERRESTRIAL RESOURCES The preliminary design of the terminal building poses some concern for fatal strikes by migratory birds both during the day and at night. Measures that have the potential to reduce daytime bird strikes include: • Place attractants (such as feeders or vegetation) either within 1 foot of the glass surface so that birds that have been attracted to them do not build up enough momentum to sustain serious injury if they hit the glass upon departure, or more than 33 feet from the glass surface; • Transform glass into a recognizable obstacle by uniformly covering glass surfaces with a decorative grid with 2- to 4-inch intervals; • Angle windows such that the panes reflect the ground instead of surrounding vegetation and sky; • Minimize use of reflective glass; and • Minimize the illumination of interiors behind clear glass and the visibility of indoor plants from outside (Klem 1990b, Klem 1991 in Ogden 1996). Measures that have the potential to decrease bird strikes of nocturnal migrants include: • Minimize amount of light emanating upward during the migratory season; and • Minimize exterior floodlighting during the migratory season. Measures to reduce potential impacts to birds from striking the surface of the street-level terminal, such as those presented above, and to minimize the potential for birds to enter the building through an opening in the top of the structure, will be explored during final design. PANYNJ will explore all feasible, cost effective, and practical measures for reducing bird strikes that are in keeping with the Terminal's design concept. FLOODPLAINS Existing and rehabilitated flood protection measures will be implemented as part of the Preferred Alternative. As such, flood control will meet or exceed pre-September 11, 2001 conditions. Stormwater discharges will be managed with an approved Stormwater Pollution Prevention Plans (SWPPPs) and established regulatory programs to minimize potential impacts to floodplains, groundwater, water quality, and aquatic resources.

Substantial impairment occurs only when the protected activities, features, or attributes of the resource are substantially diminished.

For the Permanent WTC PATH Terminal, a Section 4(f) evaluation has been prepared for the following reasons:

- The Permanent WTC PATH Terminal would be constructed within the boundaries of the approximately 16-acre WTC site (National Register-eligible) and would have an effect on this historic resource;
- The project would an adverse effect on the Hudson River Bulkhead (State and National Register-eligible);
- The project may require alteration or removal of potential archaeological resources within the eastern portion of the WTC site; and
- The project's construction may result in vibration impacts to known historic buildings within 90 feet of the project's construction zone. These resources are as follows: Barclay-Vesey Building, Former East River Savings Bank; St. Paul's Chapel and Graveyard; Beard Building; and 114-118 Liberty Street.

Both of the Project Alternatives—No Action and the Preferred Alternatives—was evaluated for their potential use with respect to Section 4(f) rules and regulations, and it was determined that each would have adverse effects to one or more of the Section 4(f) resources identified above. Alternatives were explored to determine if the Project's goals and objectives could be met without the use of the Section 4(f) resources. Two alternatives, No PATH Service to Lower Manhattan and Relocate PATH Projections could avoid one or more of the Section 4(f) resources. Although the Draft Section 4(f) statement concluded that these alternatives were feasible, they were not prudent. The U.S. Department of the Interior concurred with this finding in a letter dated July 30, 2004.

Since it has been determined that no prudent and feasible alternative would avoid the use of all of the Section 4(f) resources, PANYNJ and FTA implemented measures to minimize harm through the medium of the project's MOA pursuant to Section 106 of the National Historic Preservation Act. As described above, the MOA stipulates measures to avoid, minimize, and mitigate the Project's effects to the WTC site and the Hudson River Bulkhead.

F. CUMULATIVE EFFECTS

Generally, the long-term cumulative effects of projects currently planned for Lower Manhattan are beneficial while some of the short-term effects are adverse. Because the Lower Manhattan Recovery Projects are either improvements to existing infrastructure or replacements of facilities destroyed on September 11, 2001, they have been planned with the specific purpose of economic recovery coupled with improvements to the environment of Lower Manhattan. This is particularly true with respect to transportation, since all five of the federal Lower Manhattan Recovery Projects include elements that would improve access to, from, and within Lower Manhattan as compared to pre-September 11, 2001 conditions. However, to attain these goals, the area would experience an intense level of construction over the next several years. Therefore, this cumulative analysis gives a greater focus to minimizing and mitigating of the potential adverse effects during construction of these projects.

As described above in "Approach to Cumulative Effects," construction schedules for the World Trade Center Memorial and Redevelopment Plan, Route 9A Project, and Permanent WTC PATH Terminal have been delayed such that there would be less overlap of the peak construction activities for the five Lower Manhattan Recovery Projects. The effects of the construction schedule changes was studied, and it was determined that the impacts would not change substantially as compared to the analysis presented in the DEIS. Furthermore, the mitigation measures that are proposed would continue to be sufficient.

CONSTRUCTION PERIOD

ACCESS AND CIRCULATION

Vehicular Traffic

The *WTC Memorial and Redevelopment Plan FGEIS* contains a comprehensive examination of expected traffic conditions in the peak construction year for Lower Manhattan Recovery Projects. The analysis of cumulative traffic effects considered a total of 24 intersections. Overall, future conditions with the construction activities for the Lower Manhattan Recovery Projects would result in adverse traffic impacts at 6 intersections as follows:

- Route 9A and Vesey Street (AM peak hour)
- Church Street and Chambers Street (AM and PM peak hours)
- Church Street and Barclay Street (AM peak hour)
- Church Street and Cortlandt Street (midday peak hour)
- Broadway and Canal Street (PM peak hour)
- Broadway and Worth Street (AM, midday, and PM peak hours)

The mitigation of cumulative traffic effects of the various Lower Manhattan construction activities would also be a coordinated effort under the auspices of NYSDOT and NYCDOT, since both agencies have jurisdiction over the affected roadways. As described in the Route 9A Project SDEIS, NYSDOT would prepare a Maintenance and Protection of Traffic (MPT) Plan on behalf of the Lower Manhattan project sponsors through the either the Command Center or the Lower Manhattan Construction Coordination Group, as appropriate. The MPT Plan would include input from PANYNJ, MTA/NYCT, LMDC, and NYCDOT and would specify measures to stage construction areas (e.g., lane and sidewalk closures) while ensuring the proper circulation of traffic through Lower Manhattan (e.g., traffic diversions, parking restrictions, signal timing adjustments).

Pedestrians

Generally, crosswalks in the vicinity of the WTC site would operate at level of service D (LOS) or better during the critical construction year, and there would be no change in LOS as compared to baseline conditions. However, there would be deterioration to LOS E conditions at the intersections of Church Street and Dey Street and at Church Street and Cortlandt Street in the AM and PM peak hours. As describe above, a MPT Plan will be prepared for the Lower Manhattan Recovery Projects. This plan will include measures to ensure that safe and efficient pedestrian access and circulation is maintained throughout the construction period. Such measures may include signal timing adjustments; protected pedestrian walkways, and crossing guards. It is anticipated that the MPT Plan would be administered by the Command Center in coordination with NYSDOT, NYCDOT, PANYNJ, LMDC, and MTA/NYCT.

AIR QUALITY

The analysis of the potential cumulative impact of activities related to the construction of the Permanent WTC PATH Terminal and the other Lower Manhattan Recovery Projects on air quality consider both stationary (e.g., on-site equipment) and mobile (e.g., trucks) sources. Since almost all stationary construction equipment and trucks use diesel engines, the main pollutants of concern for local analysis are particulate matter, and nitrogen dioxide, emitted both as engine exhaust and fugitive dust, and analyzed as $PM_{2.5}$ and PM_{10}, and NO_2. An analysis of the effects of truck traffic on carbon monoxide (CO) concentrations was also conducted.

The cumulative air quality assessment was modified since publication of the DEIS to reflect changes in the project commitments for the WTC Memorial and Redevelopment Plan as well as to describe both alternatives for the Route 9A Project. LMDC incorporated additional mitigation measures (e.g., electrification and diesel particle filters) in their ROD for the WTC Memorial and Redevelopment Plan. These measures were included in this cumulative effects analysis. Furthermore, analysis was prepared for both the at-grade and short bypass alternatives for Route 9A since construction methods for both Route 9A and PATH's east-west concourse would vary.

All diesel construction engines, excluding on-road trucks, would use ultra-low sulfur diesel (ULSD) fuel. Furthermore, per the guidance of the original EPCs, engines larger than 60 horsepower (HP) would include emissions reduction measures to reduce emissions of PM and volatile organic compounds (VOCs). For the purpose of the base case analysis (i.e. without additional mitigation beyond the original EPCs), it was assumed that PM emissions from all such engines would be reduced by 40 percent—the reduction achieved by using diesel oxidation catalysts (DOC).

Maximum predicted CO concentrations in the critical analysis year were predicted at two intersections along Route 9A. These locations are of concern because of the high level of traffic currently using the roadway and the potential for construction vehicles to adversely affect traffic flow and thereby increase CO emissions at critical intersections. The analysis includes all construction vehicles from the five major Lower Manhattan Recovery Projects, which totals approximately 2,000 per day. Approximately, a third of the construction vehicles would use Route 9A to access the WTC, PATH, and Route 9A construction work areas. Maximum predicted 8-hour average CO concentrations would increase by 0.6 parts per million (ppm) over the condition without any activity from the five major projects. With that increase, total CO concentrations would still be well below the National Ambient Air Quality Standards (NAAQS).

Under the Route 9A at-grade alternative, the maximum increase in PM_{10} concentrations would be 117.9 $\mu g/m^3$ on a 24-hour basis and 4.0 $\mu g/m^3$ on an annual basis in close proximity to the site. These potential maximums would occur at the temporary bikeway along Route 9A or at the intersection of Vesey and Route 9A. The incremental increase in the 24-hour PM_{10} concentrations would exceed the NAAQS; however, with the enhanced mitigation measures described below this exceedance would not occur. Increases in PM_{10} at other locations would be significantly lower, with a maximum increase at residential locations of 26.5 $\mu g/m^3$ and 2.5 $\mu g/m^3$ on a 24-hour and annual basis, respectively.

Under the Route 9A at-grade alternative, the predicted increase in maximum $PM_{2.5}$ concentrations in the immediate vicinity of the sites would be a maximum of 82.5 $\mu g/m^3$ and 2.4 $\mu g/m^3$ on a local 24-hour average and annual average basis, respectively. The annual average increase in neighborhood scale $PM_{2.5}$ concentrations would be 0.42 $\mu g/m^3$. The maximum predicted increase in $PM_{2.5}$ concentrations would exceed the interim guidance threshold values

established by the New York State Department of Environmental Conservation. Concentrations decrease rapidly with distance from the construction sites and exceedances would not be expected at approximately 1,300 feet from the sources. However, exceedances could occur at residential receptors in closer proximity if enhanced mitigation measures were not implemented. With mitigation, increases in $PM_{2.5}$ would be reduced by approximately 66 percent, and the potential exceedance of the interim guidance thresholds would be limited to a small area adjacent to Route 9A.

The NO_2 concentrations were predicted to increase substantially under the Route 9A at-grade scenario with a maximum increment of 21.5 $\mu g/m^3$ in the immediate vicinity of the site, with the total concentration, including background levels, potentially reaching 93.5 $\mu g/m^3$. Although exceedances of the NO_2 standard are not predicted, the U.S. Environmental Protection Agency expressed concern about NO_2 as it is a precursor to ozone. The mitigation proposed to reduce particulate matter (e.g. electrification) would also reduce NO_2 emissions.

Under the Route 9A short-bypass alternative the maximum 24-hour increase in PM_{10} concentrations of 86.5 $\mu g/m^3$ an annual increase of in PM_{10} 17.1 $\mu g/m^3$, and the annual 24.3 $\mu g/m^3$ increase in NO_2 would not exceed the NAAQS. However, the maximum annual increase in $PM_{2.5}$ of 2.4 $\mu g/m^3$ and maximum 24-hour increase of 68.4 $\mu g/m^3$ would exceed the interim guidance threshold values. Similar to the at-grade alternative for Route 9A, concentrations under the short bypass scenario decrease substantially with distance from the construction sites; however, without additional mitigation there would continue would be an exceedance of the $PM_{2.5}$ interim guidance thresholds at residential receptors.

Since publication of the DEIS, the Lower Manhattan project sponsors have committed to additional mitigation that was not originally contemplated with the EPCs. The following describes these commitments.

- Electrification: Certain construction engines that operate in a fixed or temporarily fixed position, such as welding machines and compressors, could potentially be connected to the City's power grid if available by Con Edison at the start of construction. The electrification of this equipment would eliminate the on–site diesel exhaust from these sources. However, in some cases, electrification may not prove effective due to the need for mobility, and some local power generation may be needed where connection points are not available. MTA/NYCT and PANYNJ would require all contractors and subcontractors to use electric power for all diesel powered equipment that can be replaced with an electrically powered version unless access to grid power is not available. However, this does not apply to PATH's pedestrian concourse beneath Route 9A if it is constructed by NYSDOT since NYSDOT has not finalized what level of electrification is possible for its project.

- Diesel Particle Filters (DPFs): Technologies are available that can achieve greater reductions in particulate matter emissions as compared to DOCs. DPFs, for example, can reduce particulate matter emission by at least 85 percent and as high as 98 percent. However, DPFs are not effective for every type of engine operation, and there may be technical difficulties in applying DPFs to some engines. The Lower Manhattan project sponsors would require the use of DPFs or other measures with equivalent PM removal efficiency for all nonroad diesel engines of 50 horsepower or greater wherever the implementation of such a device is commercially available. At this time, it is assumed that DPFs can be used on 75 percent of nonroad diesel engines and that the remaining 25 percent could employ DOCs.

- Newer Engines: The use of new construction engines would ensure that older, higher polluting engines are not operating on–site and would make the operation of added control technologies easier and more efficient. The Lower Manhattan project sponsors would require the use of post-1995 fuel injection engines, which meet the Tier II engine emissions standards, as defined in Title 40, Part 89.112. Exceptions will be made only for specific engines that are not yet available as Tier II, where the task cannot be reasonably accomplished using alternative engines or means to comply with these demands. However, given current technology, it is assumed that all engines would be Tier II compliant.
- The Lower Manhattan project sponsors are investigating the use of other methods to reduce NO_2 emissions. However, given the current uncertainty, additional NO_2 reduction techniques were not assumed as part of the cumulative mitigation analysis.

With these enhanced mitigation measures, the potential exceedance of the PM_{10} 24–hour, NAAQS would be eliminated. Furthermore, the cumulative $PM_{2.5}$ increment would be reduced by approximately 66 percent and the potential for exceedance of 24-hour, interim guidance thresholds for $PM_{2.5}$ would be reduced to a single location, the temporary Route 9A bikeway. As described above, the NO_2 NAAQS would not be exceeded during construction. However, the proposed electrification of motors would significantly reduce NO_2 emissions, and levels of NO_2 would be further reduced if NYSDOT commits to some level of electrification for the Route 9A Project.

NOISE AND VIBRATION

The analysis of cumulative construction noise considered twelve receptor sites in Lower Manhattan. Without mitigation, the predicted cumulative levels would exceed the recommended 8-hour L_{eq} and 30-day L_{dn}/L_{eq} thresholds at the Hilton Millennium Hotel, the World Financial Center, and 114 Liberty Street, and 4 Albany Street. Cumulative levels would also exceed the recommended 8-hour L_{eq} threshold at St. Peter's Church. The Preferred Alternative, itself, would result in significant adverse noise impacts at the Hilton Millennium Hotel, the World Financial Center, and 114 Liberty Street, but these project-generated impacts would be mitigated as identified above (see Table S-5). Although the Preferred Alternative would not contribute substantially to the cumulative noise levels at 4 Albany Street and St. Peter's Church, PANYNJ, in coordination with the other Lower Manhattan project sponsors, is investigating additional measures to reduce construction period noise as described below.

PANYNJ and the other major Lower Manhattan Recovery Projects are developing construction noise mitigation measures, examples of which are provided below. Implementation of these mitigation measures is expected to minimize or eliminate construction-related individual and cumulative noise impacts. The sponsors are coordinating their efforts through the Lower Manhattan Construction Coordination Group.

- The use of acoustic barriers and walled enclosures around certain construction activities. For example, noise tents/enclosures could be used around workers using jackhammers. A temporary noise barrier of 20 feet in height could be installed along the fence line/property line of the construction zone to reduce the noise levels. In addition, temporary barriers (e.g., wood panels on top of Jersey barriers) could also be positioned adjacent to and moved along slurry walls and other construction operations, etc.;
- The placement of construction equipment in shielded locations, such as below grade in the Project Site;

- The installation of silencers on jackhammers, air compressors, generators, light plants, and cranes to reduce noise levels at specific locations (i.e., adjacent to existing residential);
- The use of electrically operated equipment, rather than combustion equipment;
- The use of soil beds, timber planking and/or exterior rubber lining on truck body and aluminum carrying case to reduce rock impact noise during truck load/unloading operations;
- The use of drive-through street-level truck enclosures for truck loading and unloading;
- The use of sheds/enclosures at concrete pump sites during concrete truck unloading; and
- The placement of most loading/unloading inside the bathtub and away from areas at street level.
- The designation of central areas within projects for noisy activities, such as cutting steel or wood or use of noisy equipment such as impact wrenches. Use of pre-cut, pre-fabricated, or modular construction materials that minimize need for on-site fabrication or cutting methods.

Programmatic measures to control construction noise levels would be undertaken throughout the construction period. These programmatic measures would be administered through either the Command Center and/or the Lower Manhattan Construction Coordination Group and may include:

- Enforcement of designated truck routes during construction;
- Adherence to construction equipment noise performance standards specified by EPA and possible development of additional standards by the LMCCG;
- Noise monitoring before construction begins, to establish baseline noise levels, and ongoing monitoring during the various construction phases; and
- Evaluation of the noise reduction potential, and cost effectiveness, of alternative construction methods and/or changes to the sequencing of construction activities.

Cumulative construction of the Lower Manhattan Recovery Projects would result in varying degrees of vibration, depending on the stage of construction, the equipment and construction methods employed, and the distance from the construction to buildings and vibration sensitive structures. Construction equipment such as pile drivers can produce levels that exceed the 0.12 and 0.20 inches per second vibration damage threshold criterion for fragile buildings at distances of 50 feet. At distances closer to the construction zone (20 feet or less), additional equipment such as clam shovel drop, caisson drilling, and large bulldozers can produce levels exceeding the vibration threshold criterion for fragile and some extremely fragile buildings. Predicted vibration levels would be 0.23 or greater at the historic/fragile buildings within 50 feet from the construction area, during activities such as pile driving. The structures most prone to potential cumulative vibration impacts are located along Fulton and Dey Streets between Church Street and Broadway, on Liberty Street west of Church Street, and on West Street near Vesey Street.

As described in the executed MOA for the Permanent WTC PATH Terminal, PANYNJ, in consultation with the State Historic Preservation Officer (SHPO) and in coordination with other Lower Manhattan project sponsors, as appropriate, would develop a Construction Protection Plan (CPP) based on the requirements laid out in the "New York City Department of Buildings Technical Policy and Procedure Notice #10/88." The CPP would avoid or minimize vibration for historic resources within 90 feet of the Terminal's construction zone.

CULTURAL AND HISTORIC RESOURCES

The Permanent WTC PATH Terminal's Area of Potential Effect (APE) contains 21 resources that are listed or are eligible for listing on the National and New York State Registers of Historic Places and/or as a New York City Landmark. The assessments of potential impacts identified 9 sites within the APE that may be impacted by the Permanent WTC PATH Terminal's construction. Because construction of the South Ferry Terminal would occur outside the APE for the Permanent WTC PATH Terminal, there is no potential for cumulative construction-period impacts from the combination of these projects. However, construction of the WTC Memorial and Redevelopment Plan, Fulton Street Transit Center, and the Route 9A Project would have cumulative construction-period effects to seven resources within the APE that may also be impacted by the Permanent WTC PATH Terminal as follows:

- Hudson River Bulkhead, Battery to 59th Street;
- Barclay-Vesey Building, 140 West Street;
- St. Paul's Chapel and Graveyard;
- Former East River Savings Bank Building, 26 Corlandt Street;
- 114-118 Liberty Street;
- Beard Building, 125 Cedar Street; and
- The WTC site.

The cumulative construction of the Permanent WTC PATH Terminal, Fulton Street Transit Center, Route 9A Project, and World Trade Center Memorial and Redevelopment Plan may generate ground-borne vibration impacts at the Barclay-Vesey Building, St. Paul's Chapel and Graveyard, Former East River Savings Bank Building, 114-118 Liberty Street, and the Beard Building. Per the stipulations of the executed MOA for the Permanent WTC PATH Terminal, these potential impacts would be resolved through a coordinated CPP, which would establish the sensitivity of fragile structures and provide stipulations to protect them during construction of the Lower Manhattan Recovery Projects. As per the guidance of the EPCs, PANYNJ would coordinate with the SHPO, the New York City Landmarks Preservation Commission, the appropriate Lower Manhattan Project Sponsors, and Section 106 consulting parties to develop and implement these plans.

The Hudson River Bulkhead may be cumulatively affected by the construction of PATH's east-west concourse and Route 9A. As described in the executed MOA for the Permanent WTC PATH Terminal, PANYNJ would develop and implement a plan to locate and identify intact portions that would be affected by the concourse's construction. This plan would be developed in consultation with SHPO and in coordination with NYSDOT. In the event that intact portions of the Bulkhead are identified within the vicinity of the east-west pedestrian concourse, PANYNJ, in consultation with SHPO and in coordination with NYSDOT, would prepare an Archaeological Resource Treatment Plan for these portions of the Bulkhead.

The executed MOA also provides for stipulations to address potential cumulative effects from construction on the WTC site. As described in the MOA, PANYNJ would request that all agencies constructing projects within the WTC site submit preliminary and pre-final documents to PANYNJ. PANYNJ and its designated historic preservation consultant would consult with SHPO and the Lower Manhattan Emergency Preservation Fund to asses whether there would be potential for a cumulative adverse effect from the Permanent WTC PATH Terminal and other WTC site projects based on the preliminary and pre-final plans. If SHPO and PANYNJ, agree that planned or completed activities would result in cumulative adverse effects on the WC site,

then PANYNJ would consider measures with respect to the Permanent WTC PATH Terminal to mitigate or minimize these effects, including technical or financial measures for the protection, stabilization, or repair of resources and/or modifications to the Preferred Alternative's design. PANYNJ would make its documentation of potential cumulative effects and accompanying mitigation plans available for review by the National Park Service, the Advisory Council on Historic Preservation, the Lower Manhattan project sponsors, and the Section 106 consulting parties. PANYNJ's plans to minimize or mitigate adverse cumulative effects would also consider the stipulations within the Programmatic Agreements for the World Trade Center Memorial and Redevelopment Plan, the Route 9A Project, and the Fulton Street Transit Center.

ECONOMIC CONDITIONS

The Lower Manhattan Recovery Projects would create thousands of construction jobs. Not only would these projects spur employment in Lower Manhattan, but they would provide jobs for the region, as a whole. These projects would also directly enhance the local economy with the expenditure of dollars for labor and materials, the generation of tax revenues, and induced benefits to local businesses in the vicinity of construction sites.

Construction activities in general have the potential to disrupt business and retail operations as a result of restricted access for pedestrians (customers) and vehicles (deliveries). The Permanent WTC PATH Terminal is unlikely to directly restrict business access for extended periods of time during construction since most activities would be contained within the WTC site. However, some access restrictions may occur on streets surrounding the WTC site with construction of the PATH's Route 9A connection as well as periods of construction for the WTC Memorial and Redevelopment Plan.

The Fulton Street Transit Center would include cut-and-cover construction with potential restrictions to access on Dey Street, Church Street, and Fulton Streets. However, a detailed staging plan is being prepared to ensure that street and sidewalk traffic can be maintained in these areas, to the extent possible.

As currently planned, NYSDOT would maintain four lanes of traffic through their construction zone during most periods of the day. In addition, NYSDOT has completed a pedestrian bridge across Route 9A at Vesey Street that connects to an at-grade, protected pedestrian walkway along Vesey Street. Together these temporary measures would maintain access between Church Street and Battery Park City for businesses, workers, commuters, and residents.

The sponsors of the Lower Manhattan Recovery Projects are working with NYSDOT and NYCDOT to develop a Construction Management Plan (CMP) for Lower Manhattan that would coordinate the MPT plans of the individual projects. The CMP would ensure access is maintained through the area as individual projects proceed into their construction phases. This coordinated plan would help to minimize the potential adverse economic effects to businesses during the construction period.

The sponsors of the Lower Manhattan Recovery Projects would also provide for temporary signage to direct vehicles and pedestrians to businesses within the construction zone. These efforts would be coordinated between the sponsors and with the effected businesses to ensure that the maximum visibility for these businesses would be achieved.

DESIGN YEAR EFFECTS

NO ACTION ALTERNATIVE

The No Action Alternative could generate up to 1,200 new vehicle trips into Manhattan in the AM peak hour by 2025. These new vehicle trips would congest area roadways and would limit access to businesses for customers and deliveries. The No Action Alternative would also increase on-street pedestrian congestion since it would not provide for sub-grade concourses through the WTC site. Thus, there would be significant crowding of crosswalks and sidewalks on and near the WTC site, resulting in reduced traffic flow. Furthermore, the larger volume of pedestrians that would cross Route 9A would limit the future roadway's ability to process vehicular traffic and may necessitate the construction of a pedestrian bridge.

Because the No Action Alternative would increase vehicular traffic in Lower Manhattan, it would increase emissions and noise levels. The cumulative effect of a No Action Alternative for the Permanent WTC PATH Terminal may degrade air quality and noise levels as compared to pre-September 11, 2001 conditions. Over the long-term, increased traffic congestion, reduced air quality, and higher noise levels would degrade the quality of life for Lower Manhattan's residents and workers.

Increased congestion associated with the No Action Alternative would limit access to, from, and within Lower Manhattan. This would degrade the ability of visitors to access the areas many cultural sites and would reduce the capabilities of local businesses to process customers and deliveries. Because the No Action Alternative may limit or fully disrupt direct transit service between Lower Manhattan and New Jersey, it may force residents, commuters, and visitors to use more costly or more time consuming modes of travel. By reducing access to and from Lower Manhattan, the No Action Alternative has the potential to stagnate the overall recovery of Lower Manhattan, including the full redevelopment of the WTC site.

PREFERRED ALTERNATIVE

The Preferred Alternative has been planned and designed in cooperation with the Lower Manhattan Recovery Projects in its vicinity including the Fulton Street Transit Center, Route 9A Project, and the WTC Memorial and Redevelopment Plan. In the long-term, these projects would collectively provide for the integration of land use and transportation in the vicinity of the WTC site and would be an enhancement over pre-September 11, 2001 conditions.

The Preferred Alternative would form a critical sub-grade pedestrian link between Battery Park City and Church Street via the WTC site. The proposed connection between the Permanent WTC PATH Terminal and Fulton Street Transit Center's Dey Street Underpass would provide all-weather access between Tran-Hudson Ferries and the World Financial Center and the majority of the subway lines that serve Lower Manhattan. Furthermore, the Route 9A connection would reduce at-grade pedestrian trips during peak commuter periods. As a result, traffic circulation would be improved in the vicinity of the WTC site, which has resultant economic, traffic, air quality, and noise benefits.

The collection of transit services that would be offered by a Permanent WTC PATH Terminal in concert with a new trans-Hudson ferry terminal; a Fulton Street Transit Center; and other potential transportation projects, such as JFK airport access, would strengthen Lower Manhattan's role as a regional transit hub. As such, the area would attract scores of daily commuters and visitors who would frequent local retail establishments such as shops and restaurants. Further-

more, the integration of numerous transit services with the ability to serve residents throughout the region would increase the attractiveness of Lower Manhattan as a center of commerce.

G. PUBLIC PARTICIPATION AND AGENCY INVOLVEMENT

PUBLIC AND AGENCY INVOLVEMENT ACTIVITIES TO DATE

A comprehensive public involvement program was implemented for this project. The public involvement effort was designed to help provide complete information, to be early, timely in public notice, to be broad in public outreach, and to be responsive. The process requires extensive and intensive outreach to private citizens, local businesses and associations, development authorities, elected officials, affected government agencies and others in New Jersey and New York.

A project mailing list was developed for the distribution of outreach materials related to the environmental review process for the Permanent WTC PATH Terminal. The list currently contains approximately 500 addressees representing elected officials; federal, state, and local agencies; Technical Advisory Committee (TAC) members; Section 106 consulting parties; community and interest groups; local property owners and managers; and any members of the public who have requested mailings, including those who attended the public scoping meetings and the public hearings on the DEIS. Public outreach materials have been and will continue to be distributed throughout the environmental review process for this EIS. These activities and mailers include: flyers; mobile public information centers; newsletters; and postings to the project's website.

In addition, FTA and PANYNJ have organized formal and informal public meetings to inform elected officials, public agencies, community and interest groups, local stakeholders, and the general public of the progress of this environmental review process. These forums include:

- Federal Inter-Agency Review Team Meetings;
- Technical Advisory Committee Meetings;
- Section 106 Consulting Party Meetings;
- Congressional Briefings;
- Stakeholder Briefings;
- Community Board Briefings;
- Presentations to Community, Advisory, and Technical Interest Groups;
- Public Scoping Meetings; and
- DEIS Public Hearings.

As described previously, the Permanent WTC PATH Terminal is part of the larger, ongoing redevelopment effort in Lower Manhattan. Thus, the planning and construction of a project alternative for a Permanent WTC PATH Terminal must be coordinated with other current planning efforts in Lower Manhattan. To that end, FTA and PANYNJ have been active participants in a number of forums working with the other federal, state, and local agencies and groups having a role or interest in the overall redevelopment efforts. These forums have included:

- Coordinated Section 106 Consulting Party meetings for the WTC site;
- Federal Inter-Agency Review Team;
- Lower Manhattan Construction Coordination Group; and
- The Technical Advisory Committee to the Permanent WTC PATH Terminal.

Agency coordination efforts will continue throughout the further planning, design, and construction of the Permanent WTC PATH Terminal. As the Lower Manhattan Recovery Projects move from their early planning phases to design and construction, coordination efforts will focus both independently and through the Lower Manhattan Construction Command Center on the implementation of the EPCs, construction logistics, contract specifications, and ongoing public outreach. The goal of these efforts is to achieve the greatest long-term benefits for Lower Manhattan and the region as a whole while minimizing the short-term, adverse construction period impacts.

FTA AND PANYNJ CONTACTS

Chapter 1: Purpose and Need

A. INTRODUCTION

Trans-Hudson transit service between New Jersey and New York has long been an integral part of the Lower Manhattan transportation system. Prior to the terrorist attacks of September 11, 2001, the World Trade Center's (WTC) Port Authority Trans-Hudson (PATH) Terminal served some 67,000 daily boardings and was the gateway to Lower Manhattan for most commuters from west of the Hudson River. However, the attacks resulted in extensive damage to the PATH system including the destruction of its WTC Terminal. As a result, the system lost a substantial portion of its capacity to serve commuters throughout the New York and New Jersey region and mass transit access to Lower Manhattan was severely hindered.

Since September 11, 2001, those commuting between Lower Manhattan and communities west of the Hudson River have resorted to often less convenient, more time-consuming, and more expensive modes of travel. Although a temporary PATH station has been constructed on the WTC site, it will not support the future development planned for the area nor does it meet the long-term needs of commuters.

A Downtown Transportation Hub, herein referred to as the Permanent WTC PATH Terminal, is proposed to be a full service, regional transportation facility that would be integrated with the existing and future transportation infrastructure on and near the WTC site, future WTC site development, and the surrounding area. This Project is needed to reestablish and enhance transportation facilities that existed at the WTC complex before September 11, 2001 and to ensure the long-term accessibility and economic vitality of Lower Manhattan.

The U.S. Congress has committed $21 billion to New York City since September 11, 2001 to support a variety of programs including clean up and recovery efforts, economic aid to residents and businesses, survivorship benefits, human services and crisis counseling, health programs, and infrastructure (Public Laws 107-38, 107-117, and 107-206). This federal relief package contains four elements: FEMA assistance, Community Development Block Grants, Liberty Zone Economic Stimulus Package, and appropriations to specific agencies to fund programs for Lower Manhattan. The $4.55-billion transportation recovery effort, which includes funds for this Project, is being administered through FEMA and the FTA. Although the grant package would be jointly funded, FTA is serving as the lead agency as agreed to in a Memorandum of Understanding (August, 2002) and subsequent correspondence between the agencies (November 18, 2002).

This chapter provides background information on the PATH system, its WTC Terminal, and Lower Manhattan in general; characterizes PATH's ridership; defines the need for this Project; and outlines the goals and objectives that it would achieve.

B. HISTORICAL OVERVIEW

THE PATH SYSTEM

PATH is an electrified heavy-rail transit system with a total of 13 stations (see Figure 1-1 and Table 1-1). It is a fully owned subsidiary corporation of PANYNJ, which acquired the system as the Hudson & Manhattan (H&M) Railroad in 1962. PATH is recognized by the federal oversight agencies as a commuter rail system. Therefore, it operates according to policies and procedures set forth by the USDOT Federal Railroad Administration (FRA).

Table 1-1
PATH Stations and Connecting Transit Services

Station	Location	Connecting Service
9th Street	Sixth Ave. at 9th St., New York, NY	NYCT Subway, NYCT bus service
14th Street	Sixth Ave. at 14th St., New York, NY	NYCT Subway, NYCT bus service
23rd Street	Sixth Ave. at 23rd St., New York, NY	NYCT Subway, NYCT bus service
33rd Street	Sixth Ave. between 30th and 33rd Streets, New York, NY	Amtrak, NJ Transit and LIRR commuter rail, NYCT Subway; NYCT, and private bus service
Christopher Street	Christopher St. between Greenwich and Hudson Streets, New York, NY	NYCT Subway, NYCT bus service
Exchange Place	Montgomery St. at Hudson River, Jersey City, NJ	Hudson-Bergen Light Rail, NY Waterway ferry, NJ Transit, and local bus service
Grove Street	Newark Ave. between Grove St. and Luis Munez Marin Blvd., Jersey City, NJ	Coach, NJ Transit, and local bus service
Harrison	Frank E. Rodgers Blvd. between Somerset and Cape May Streets, Harrison, NJ	NJ Transit bus service
Hoboken	Hudson Place at River Street, Hoboken, NJ	NJ Transit and Metro-North commuter rail, Hudson-Bergen Light Rail, NY Waterway ferry, NJ Transit, and local bus service
Journal Square	Kennedy Blvd. between Pavonia and Sip Avenues, Jersey City, NJ	A&C, Bergen Avenue, Central Avenue, Community Lines Hudson, County Executive Express, Carefree, Red & Tan, Lafayette-Greenville, NJ Transit, and local bus service
Newark	1 Penn Plaza West, Newark, NJ	Amtrak and NJ Transit commuter rail, Newark City Subway, Greyhound, NJ Transit, and private bus service
Pavonia/Newport	Washington Blvd. at Pavonia Ave., Jersey City, NJ	Hudson-Bergen Light Rail, NY Waterway ferry, NJ Transit, and local bus service
World Trade Center	Fulton St. at Church St. New York, NY	NYCT Subway, NY Waterway and Water Taxi ferries, NYCT, and private bus service

Note: Information for the World Trade Center station reflects temporary PATH service.

PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure 1-1
PATH System

PATH has four routes: Newark-WTC, Hoboken-WTC, Journal Square-33rd Street, and Hoboken-33rd Street. Trains operate 24 hours a day, seven days a week, although routes are modified somewhat during late night and weekend hours.

PATH directly serves communities in Jersey City, Newark, Hoboken, and Manhattan but also provides connections for other west-of-Hudson residents. At Newark-Pennsylvania Station, PATH customers can access Amtrak, New Jersey Transit's (NJ Transit) Northeast Corridor, Raritan Valley, and North Jersey Coast commuter rail lines; the Newark City Subway; and bus and rail service to Newark Liberty International Airport. In Hoboken, PATH connects with Metro-North Railroad's Port Jervis line; NJ Transit Boonton, Morris & Essex, Main/Bergen County, Pascack Valley, and North Jersey Coast commuter rail lines; numerous NJ Transit bus routes; ferry service; and the Hudson-Bergen Light Rail. In New York, PATH stations are located in close proximity to New York City Transit (NYCT) subway stations serving a total of 20 subway lines. There are also connections to NYCT and privately operated bus routes, ferries, and commuter rail service.

HISTORY OF PATH SERVICE TO LOWER MANHATTAN

THE HUDSON & MANHATTAN TERMINAL

The Hudson & Manhattan (H&M) Railroad began operation of the Hudson Tubes to Lower Manhattan in 1909. The Hudson Tubes provided transit service between Hudson and Essex Counties in New Jersey and the Hudson Terminal in Lower Manhattan. The Hudson Tubes served both as a commuter service and as a connection to Manhattan for short- and long-distance rail customers arriving at Newark Pennsylvania Station, Hoboken Terminal, and Exchange Place.

The Hudson Terminal was located between Greenwich, Cortlandt, Church, and Fulton Streets parallel to the two subway lines. Above street level, the H&M constructed what was then the world's largest office building, consisting of two towers. Beneath the towers was the station itself, which occupied two city blocks. The station contained three levels: a pedestrian concourse with stores, restaurants, and services; a train level with five tracks; and a powerhouse level. The H&M Terminal formed a loop with the tunnels to and from New Jersey. Eastbound trains would enter the station from the south river tunnel and exit westbound through the north river tunnel.

When the H&M Railroad began to experience major financial difficulties, the States of New York and New Jersey looked to PANYNJ to assume control of the system. In 1962, the States enacted legislation authorizing PANYNJ to undertake a port development project consisting of 1) a World Trade Center; 2) the Hudson Tubes; and 3) certain extensions of the Hudson Tubes. PANYNJ was authorized to cooperate with other government agencies in the rehabilitation and redevelopment of the WTC, its environs, and the Hudson Tubes, for the purpose of renewal and improvement of these areas as part of the port development project.

The legislation of 1962 mandated that PANYNJ acquire, rehabilitate, and operate the rail transit property associated with the H&M Railroad and the Hudson Tubes, either directly or through a wholly owned subsidiary corporation. Accordingly, PANYNJ established the Port Authority Trans-Hudson (PATH) Corporation, which acquired, by condemnation, the railroad, its equipment, and its assets, including the Hudson Terminal building.

As mandated by the legislation of 1962, PANYNJ planned and constructed a WTC on an approximately 16-acre site that included the area bounded by Church Street, Liberty Street,

Route 9A, and Vesey Street, with an extension to the north to include the block that would become 7 World Trade Center (7 WTC). In connection with the construction of the WTC, PANYNJ razed the Hudson Terminal and replaced it with a new facility, which was located beneath the office towers of the WTC.

THE WTC PATH TERMINAL

The WTC PATH Terminal opened in 1971. It was constructed west of the original H&M Terminal in the portion of the WTC site referred to as the "bathtub" and was located beneath the office and retail space. The Terminal was fully compliant with the Americans with Disabilities Act (ADA; 24 USC §§12101 et seq.; 49 CFR Parts 27, 30, and 38), and it was the first station in the world to be fully climate controlled.

The platform level contained three 10-car platforms and five tracks. The orientation of the platforms and the track configuration was similar to the H&M Terminal such that trains entered the station from New Jersey via the south Hudson River tunnel (Tunnel F) and exited to New Jersey via the north tunnel (Tunnel E). Thus, the platform level formed the loop in the PATH system allowing trains to enter and leave Manhattan without changing the location of the train's engineer or conductor. As a result, trains could have a relatively short dwell time at the Terminal.

A mezzanine was located above the platforms, housing vertical circulation between the platforms and levels above, fare equipment, and accessory retail and food stalls. The principal access between the mezzanine and the WTC retail concourse was a bank of escalators that traveled upward under NYCT's 1 and 9 line. The escalators terminated in a portion of the retail concourse known as PATH Square.

As shown in Figure 1-2, PATH Square was located in the northeast portion of the WTC retail concourse. The retail concourse provided for all-weather connections between PATH, the office buildings on the WTC site, the World Financial Center, NYCT subways, and street level. From PATH Square, passengers could access three NYCT subway stations with connections to five NYCT subway routes (1, 9, E, N, and R) via the corridors of the WTC retail concourse. (The World Trade Center Station provided direct access to the E route, but connected with the Chambers Street Station on the A and C routes and the Park Place Station on the 2 and 3 routes.) The retail concourse had street-level access from Church, Vesey, Route 9A, and Liberty Streets. A second-level pedestrian bridge over Route 9A provided a connection between the retail concourse via 1 WTC and the World Financial Center.

On September 11, 2001, the WTC PATH Terminal and a seven-car PATH train were destroyed. Subsequently, Tunnels E and F under the Hudson River were flooded, and PATH's Exchange Place Station in Jersey City, New Jersey, was damaged and rendered inoperable because the track configuration would not allow trains to turn around before entering the Hudson River tunnels. As a result, the PATH system lost a substantial portion of its capacity to serve commuters throughout the New York and New Jersey region, and mass transit access to Lower Manhattan was severely hindered.

CURRENT PATH SERVICE TO LOWER MANHATTAN

Rescue and recovery operations began in and around the WTC site immediately following September 11, 2001. Work on the WTC site continued 24 hours a day, seven days a week, for approximately nine months. During this period, the New York City Department of Design and

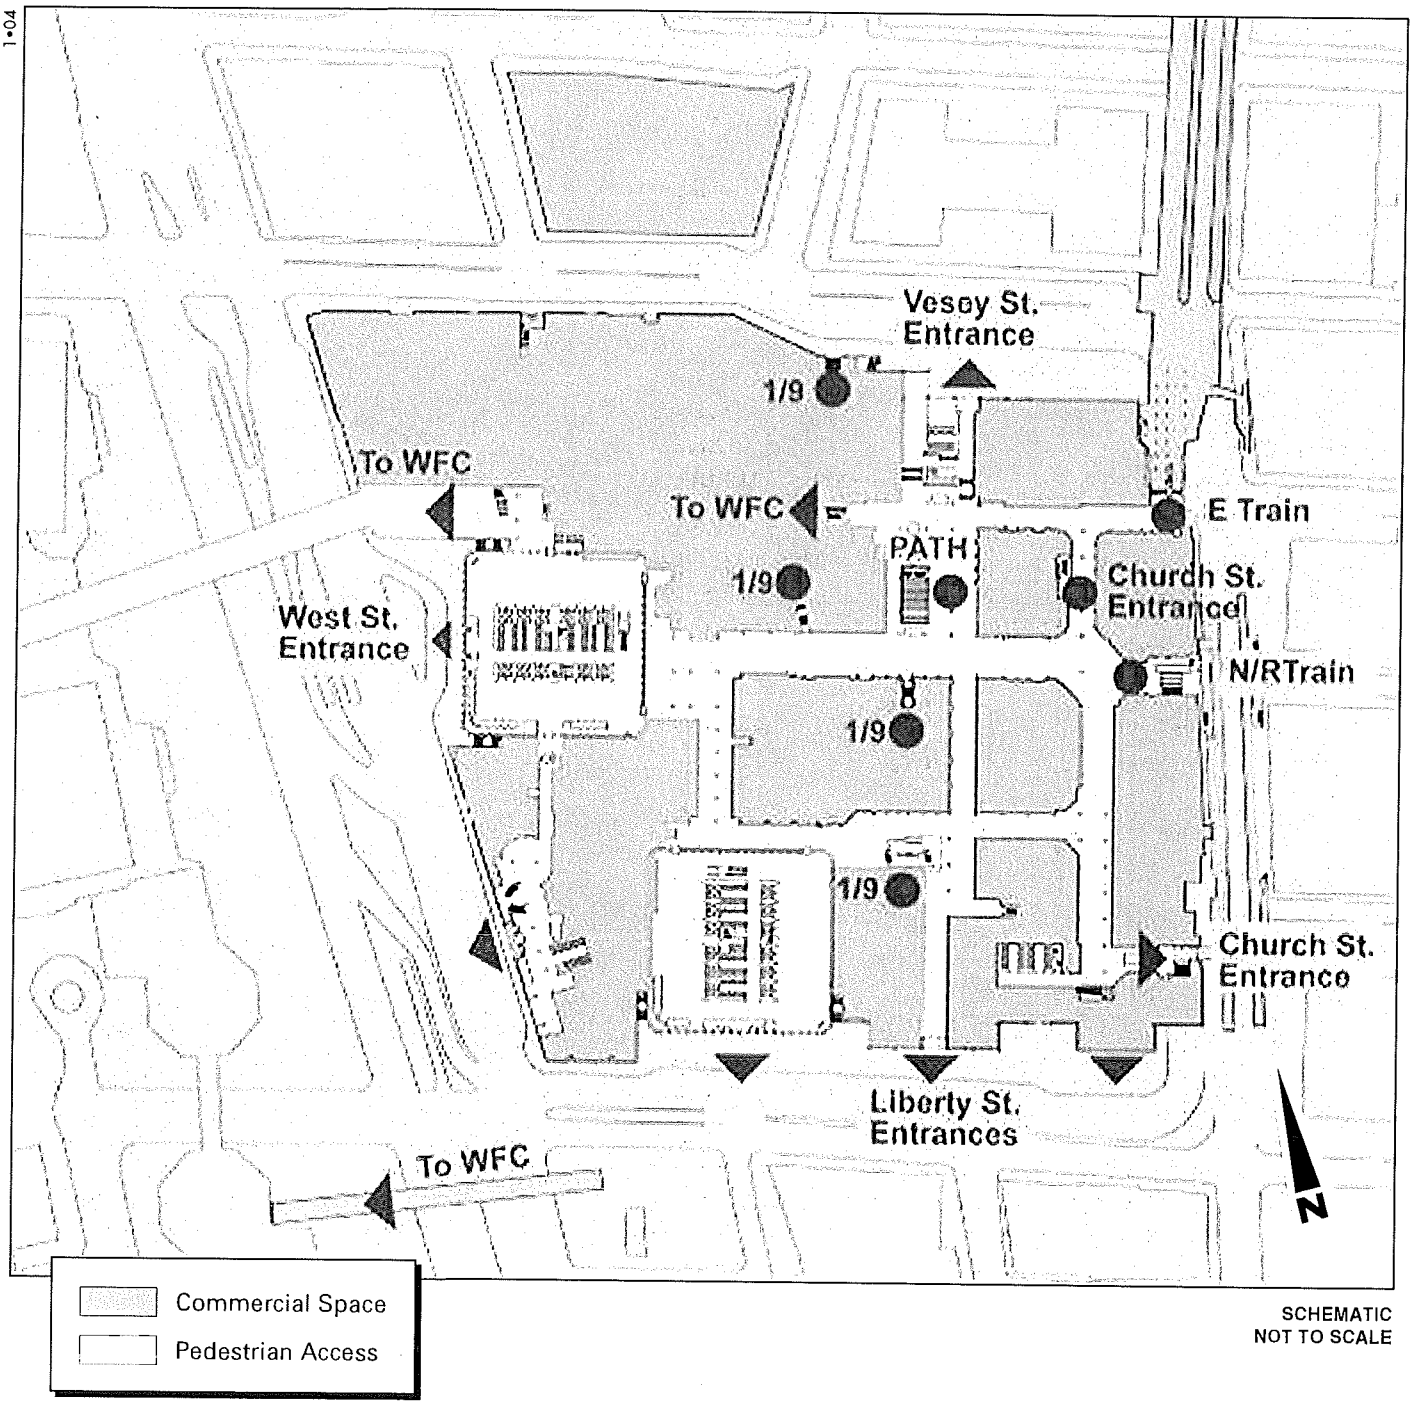

Figure 1-2

Pre-September 11, 2001
WTC PATH Terminal

Construction (NYCDDC) controlled the WTC site and was responsible for material removal, including contracting with private entities to provide such services in coordination with various federal and state entities. Control of the portion of the site that contained 7 WTC was returned to PANYNJ on May 7, 2002. The balance of the site was returned on June 30, 2002.

In February 2002, PANYNJ commenced work on the expansion of PATH's Exchange Place Station as well as repairs to the tunnels under the Hudson River. This work included electrical and signal replacements for components destroyed by water damage and excavation for new track crossovers and other improvements required to bring the station back in service. The Exchange Place Station was reopened to passengers on June 29, 2003.

PANYNJ began construction on a temporary WTC PATH station in July 2002, which was opened on November 23, 2003. The temporary station is located in the WTC "bathtub." It has five tracks and three eight-car platforms and provides street-level access through a single entry/exit at the intersection of Fulton and Church Streets. There are also direct connections to stations on NYCT's E, R, and W routes. (In February 2004, NYCT implemented long-term service adjustments that route N trains over the Manhattan Bridge and W trains over the local line to Whitehall Street. Thus, N trains no longer serve the Cortlandt Street Station.)

PATH RIDERSHIP

PRE-SEPTEMBER 11, 2001 REGIONAL TRAVEL TO MANHATTAN

The New York Metropolitan Transportation Council (NYMTC) periodically collects data to characterize daily trips to and from Manhattan's Central Business District (CBD). Referred to as hub bound counts, these data reflect regional travel to areas of Manhattan south of 60th Street. NYMTC classifies the data by cordon, which is the point where a person enters the Manhattan CBD. Five cordons have been defined: 60th Street, Brooklyn, Queens, New Jersey, and other (Roosevelt Island Tram and Staten Island Ferry).

The hub bound data reflects all trips into and out of the CBD, including work trips, non-work trips, and commercial vehicle trips. The New Jersey cordon includes all vehicular and transit trips into Manhattan for the modes and crossings south of 60th Street, including the Lincoln and Holland Tunnels, NJ Transit and Amtrak tunnels, PATH tunnels, and ferries. However, those entering the CBD via the George Washington Bridge are counted as part of the 60th Street cordon.

In the year 2000, the New Jersey cordon accounted for 14 percent of the approximately 3.9 million daily trips into the Manhattan CBD (see Table 1-2). During the AM peak period (7AM to 10AM), some 17 percent of trips crossed the New Jersey cordon, and in the AM peak hour, nearly 1 in 5 entered via the New Jersey cordon.

As shown in Table 1-3, transit riders comprised the majority of trips into Manhattan via the New Jersey cordon. The combined ridership of PATH, NJ Transit and Amtrak rail, commuter buses, and private ferries represented 62 percent of the total daily trips. The transit share was even higher at 75 percent and 81 percent during the AM peak period and AM peak hour, respectively.

PATH riders represented 30 percent of the total AM peak hour trips, 26 percent of the total AM peak period trips, and 23 percent of the total daily trips into Manhattan from the New Jersey cordon. As shown in Table 1-4, between 60 and 70 percent of these PATH trips used the downtown lines between Exchange Place and the WTC.

Table 1-2
2000 Weekday Hub Bound Trips by Sector

Sector	Peak Hour (8AM – 9AM)		Peak Period (7AM – 10AM)		24 Hour	
	Number	Percent	Number	Percent	Number	Percent
60th Street	155,130	25%	380,142	25%	1,482,768	38%

PRE-SEPTEMBER 11, 2001 PATH RIDERSHIP

Prior to September 11, 2001, the PATH system had approximately 257,000 boardings on an average weekday (see Figure 1-3). The WTC was the busiest of the 13 PATH stations with approximately 67,000 average weekday boardings. The WTC Terminal supported an average weekday two-way patronage of approximately 140,000 riders.

Volumes at the WTC Terminal were heaviest during the AM and PM peak hours. During these periods, the principal direction of travel was inbound to Manhattan in the AM and outbound to New Jersey in the PM; however, approximately 15 percent of riders commuted in the reverse direction. In the morning peak (8AM to 9AM), a total of approximately 26,000 riders used the station with 22,000 alighting and 4,000 boarding. In the evening peak (5PM to 6PM), the terminal accommodated 20,000 riders with 16,000 boardings and 4,000 alightings.

Table 1-5 shows the origins and destinations of PATH riders within Lower Manhattan during the AM and PM peak hours based on surveys conducted by PANYNJ in 1996. For those commuting to Lower Manhattan from New Jersey in the AM peak hour, the majority (61 percent) were destined to off-site buildings; 24 percent remained on the WTC site; and the remaining 15 percent connected to NYCT subways. For those leaving Lower Manhattan via PATH in the AM peak hour, some 65 percent accessed the system from NYCT subways; 3 percent from the WTC site itself; and another 32 percent from off-site buildings. Similar origins and destinations were observed for the PM peak hour.

Table 1-5
Pre-September 11, 2001 Origins and Destinations of Riders at the WTC PATH Terminal

Origin/Destination	Commuters to Lower Manhattan		Commuters from Lower Manhattan	
	AM Peak (Exit PATH)	PM Peak (Enter PATH)	AM Peak (Enter PATH)	PM Peak (Exit PATH)
NYCT Subways	15%	19%	65%	65%
WTC Site	24%	25%	3%	4%
Off-Site	61%	56%	32%	31%

Sources: Port Authority of New York and New Jersey

Table 1-6 shows the origins/destinations for those traveling between the WTC PATH Terminal and off-site developments. For those commuting to Lower Manhattan from New Jersey in the AM peak hour, the primary off-site destination was southeast from the WTC site toward the Financial District, representing about 40 percent of the total off-site trips. Trips to the north (Tribeca), northeast (Civic Center), and west (World Financial Center and Battery Park City) were fairly evenly distributed, each representing about 16 to 20 percent of the total off-site trips.

In the PM peak hour, there was a lower percentage of trips entering PATH from off-site; however, the distribution of these trips was similar to the AM peak hour.

Table 1-6
Pre-September 11, 2001 Off-Site Origins and Destinations of Riders at the WTC PATH Terminal

To/From	Commuters to Lower Manhattan		Commuters from Lower Manhattan	
	AM Peak (Exit PATH)	PM Peak (Enter PATH)	AM Peak (Enter PATH)	PM Peak (Exit PATH)
West (World Financial Center and Battery Park City)	20%	17%	5%	6%
North (Tribeca)	16%	21%	19%	28%
Northeast (Civic Center)	16%	22%	62%	53%
Southeast (Financial District)	40%	32%	13%	13%
South: Greenwich South	8%	6%	1%	1%
Sources: Port Authority of New York and New Jersey				

For those commuting from Lower Manhattan to New Jersey during the AM peak hour, the majority (62 percent of the total off-site trips) entered PATH from the northeast. Another 19 percent entered from the north (Tribeca); 13 percent from the southeast (Financial District); 5 percent from the west (World Financial Center and Battery Park City); and 1 percent from the south. A similar pattern of off-site trips was observed during the PM peak hour.

Approximately 5,900 and 5,700 commuters transferred between PATH and NYCT's subways during the AM and PM peak hours, respectively. The transfer to/from NYCT's WTC Station (E) was the most heavily used, representing approximately 55 percent of the transfer volume. One-third of the transfers were between PATH and NYCT's N and R trains, and the remaining 12 percent transferred to or from NYCT's 1 and 9 trains.

THE WTC CONCOURSE

The WTC retail concourse was an important, all-weather link to destinations within and around Lower Manhattan. Although PATH riders comprised the largest portion of pedestrians using the concourse during peak hours, thousands of other commuters traversed the facility en route to or from work. In both the AM and PM peak hours, some 19,000 non-PATH commuters entered or exited the concourse transferring between NYCT subways, buildings on the WTC site, and off-site developments.

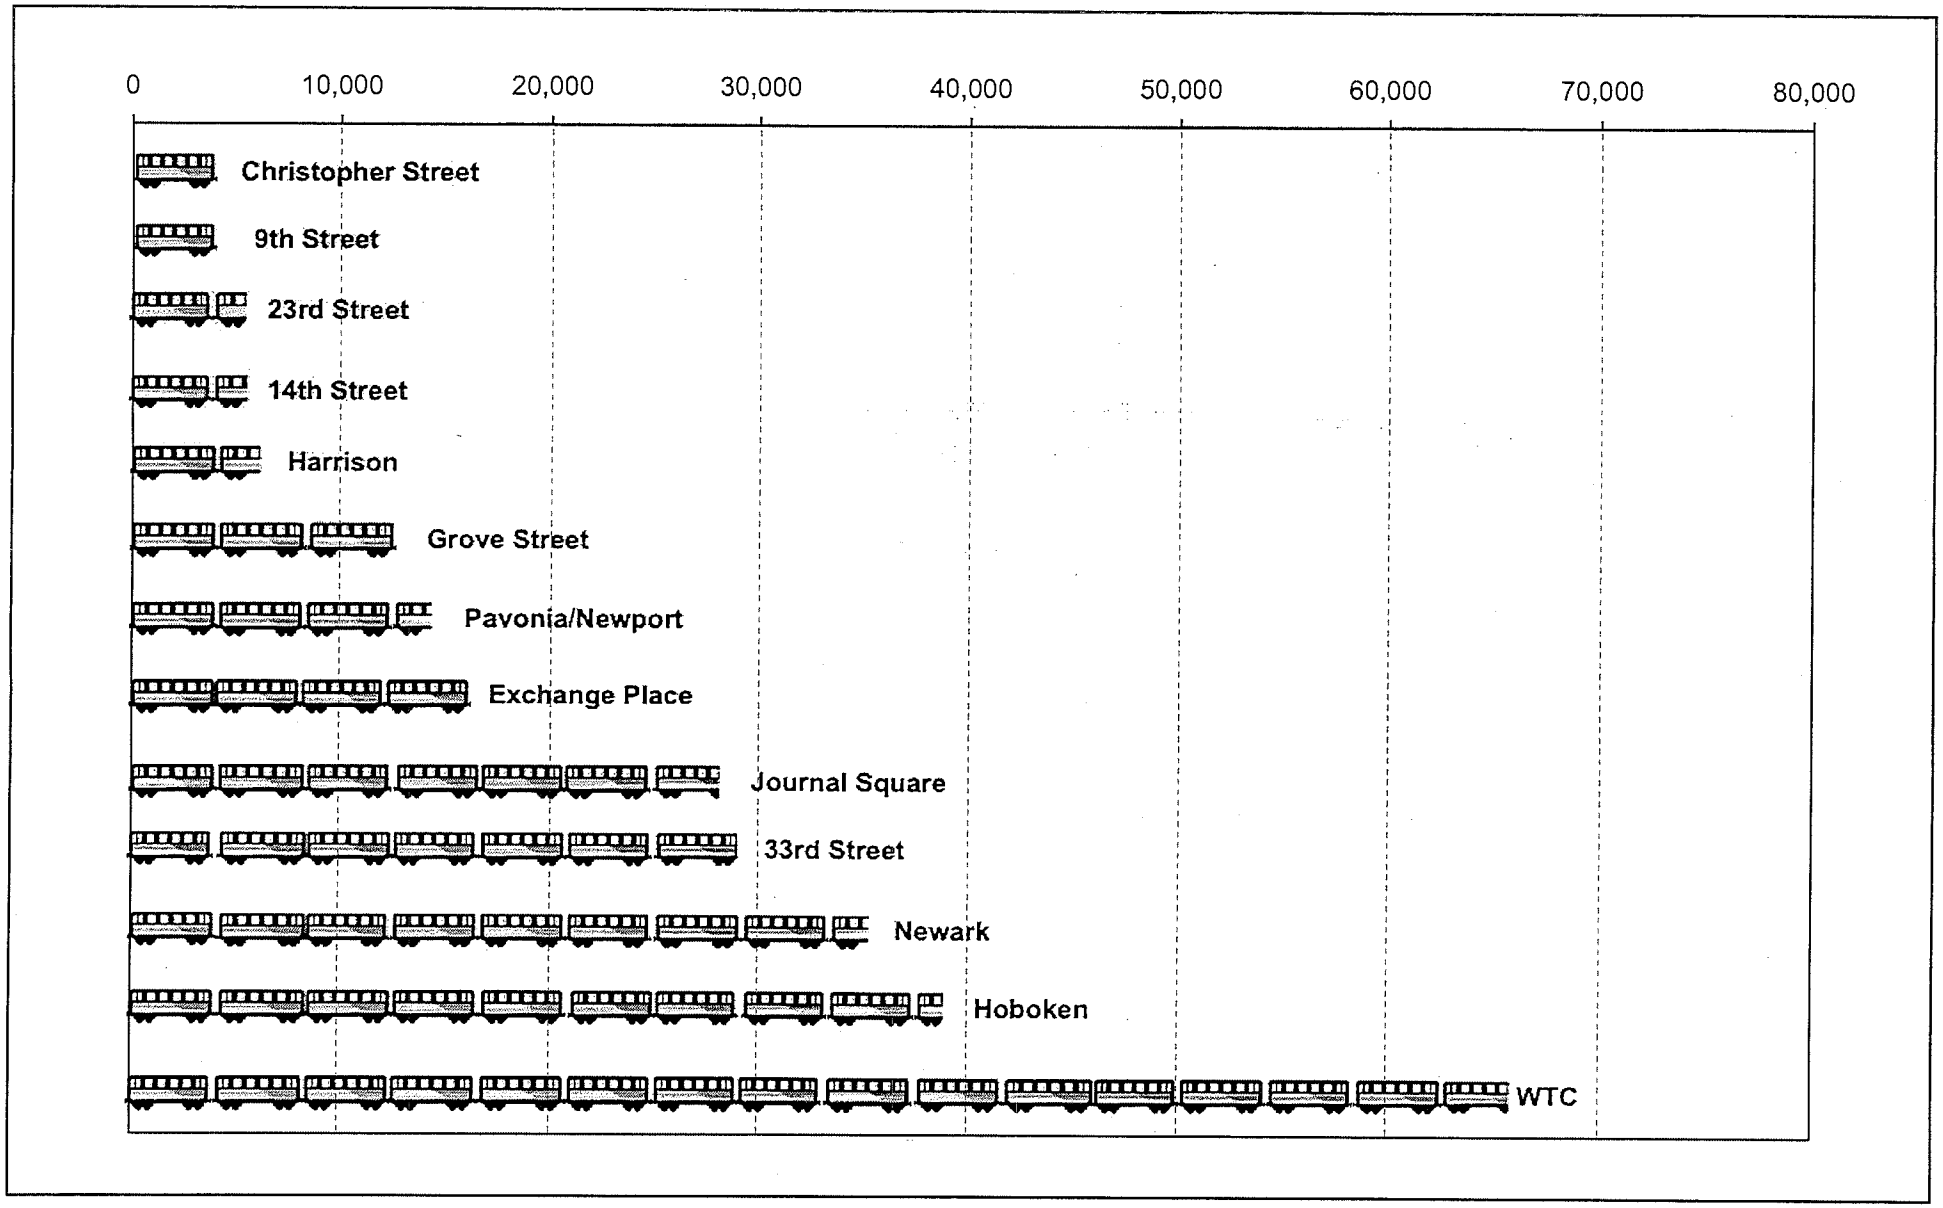
CURRENT PLANNING CONTEXT

LOWER MANHATTAN RECOVERY PROJECTS

Since September 11, 2001, several projects have been planned to redevelop and revitalize Lower Manhattan. Replacement and enhancement of transportation facilities, office, retail and hotel spaces, museum and cultural facilities, and open space are essential to the economic success of Lower Manhattan. Presently, four environmental reviews are being or have been prepared under NEPA independent of this Project, as described below.

World Trade Center Memorial and Redevelopment Plan

New York Governor George Pataki and New York City's then-Mayor Rudolph Giuliani formed the Lower Manhattan Development Corporation (LMDC) in November 2001, as a subsidiary of



PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure 1-3
Pre-September 11, 2001 Daily Boardings

the New York State Urban Development Corporation (UDC) which does business as the Empire State Development Corporation (ESDC), a political subdivision and public benefit corporation of the State of New York. LMDC will oversee the revitalization and rebuilding of Lower Manhattan, defined as the areas south of Houston Street.

LMDC is undertaking, in cooperation with the United States Department of Housing and Urban Development (HUD) and PANYNJ, a World Trade Center Memorial and Redevelopment Plan. The plan includes the construction of a WTC Memorial and memorial-related improvements, as well as commercial, retail, and hotel space; museum and cultural facilities; open space; new street configurations; and infrastructure improvements at the WTC site and adjacent parcels.

The World Trade Center Memorial and Redevelopment Plan is independent of this Project and is undergoing a separate environmental review. LMDC is conducting a coordinated environmental review of their proposed action, pursuant to federal statute, as the recipient of HUD Community Development Block Grant program funds (42 USC 5304(g)), and as lead agency under NEPA and the New York State Environmental Quality Review Act (SEQRA) and its implementing regulations (6 NYCRR Part 617). LMDC published a Generic Environmental Impact Statement for this project and a Record of Decision was issued in June 2004. Consult the project's website (www.renewnyc.com) for current information about the WTC Memorial and Redevelopment Plan.

Fulton Street Transit Center

The Fulton Street Transit Center is a project being proposed by the Metropolitan Transportation Authority (MTA). The Fulton Street Transit Center (FSTC) will rehabilitate, reconfigure, and enhance the multilevel complex of subway stations serving nine different lines in the area of Fulton Street and Broadway. The project will improve platforms, mezzanines, and connecting corridors, and will provide a new central concourse with an above-grade presence. The facility has a proposed Dey Street concourse to NYCT's Cortlandt Street Station (R and W) and the Permanent WTC PATH Terminal. The FSTC is projected for completion in 2008.

The FSTC project is independent of this Project and is undergoing a separate environmental review by the FTA and MTA. A Draft Environmental Impact Statement for the FSTC was published in May 2004 and a Final Environmental Impact Statement was published in October 2004. FTA issued a Record of Decision on the project in November 2004. Consult the project's website (www.mta.info) for current information about the FSTC project.

Route 9A Project

The New York State Department of Transportation (NYSDOT) is currently considering the reconstruction of Route 9A south of Chambers Street with either at-grade improvements or a below-grade bypass for vehicular through traffic. The reconstruction of Route 9A is independent of this Project and is undergoing a separate environmental review by the USDOT, Federal Highway Administration (FHWA), and NYSDOT. A Draft Supplemental Environmental Impact Statement was published in May 2004 and a Final Environmental Impact Statement will be published in spring or summer of 2005. Consult the project's website (www.route9A.com) for current information about the Route 9A Project.

South Ferry Terminal

MTA, in cooperation with FTA, proposes to reconstruct the South Ferry Terminal on the 1 and 9 line. Presently, South Ferry is a loop station with a single platform that can only accommodate

five-car trains. MTA proposes to replace the loop station with a stub-end terminal having two tracks and one platform able to accommodate 10-car trains. This project would increase both the capacity of the South Ferry Terminal and the 1 and 9 line during peak periods. This project is independent of the Permanent WTC PATH Terminal and is undergoing a separate environmental review by the FTA and MTA. A Environmental Assessment was published in May 2004, and a Finding of No Significant Impact was issued in August 2004. Consult the project's website (www.mta.info) for current information about the South Ferry Terminal.

OTHER DOWNTOWN PROJECTS

Before September 11, 2001, several projects were planned downtown that are still under study. These include commercial and residential buildings at Battery Park City and within the Washington Street Urban Renewal Area as well as offices, open space, cultural institutions, and modest commercial development throughout Lower Manhattan.

Federal, state, and local initiatives have been implemented to encourage private development in Lower Manhattan. The Liberty Bonds program provides federal funds for commercial and residential development in Lower Manhattan, which has resulted in the conversion or construction of several new apartment and condominium buildings. LMDC is overseeing Governor Pataki's short-term capital projects, which include temporary pedestrian connections across Route 9A, streetscape improvements, security improvements at the New York Stock Exchange, the reopening of Millennium High School, and public open space and art.

C. PROBLEM DEFINITION

ECONOMIC RECOVERY

Transportation links have long been critical to the commercial development of Lower Manhattan. In its early days, Lower Manhattan was the center of the region's sea commerce with its numerous riverfront ports. As its economy shifted to office-sectors, Lower Manhattan depended on modes of transportation that would deliver workers to and from the area. Formerly the Hudson Tubes and now PATH, the transit link between New Jersey and New York was and is integral to the movement of employees to and from their Lower Manhattan offices. More recently, employment centers have emerged in Jersey City and Newark. These businesses depend on PATH to deliver workers from New York City and other points east of the Hudson River. Furthermore, several major businesses have located facilities in both Lower Manhattan and Jersey City to allow for office expansion while maintaining a close connection between company functions on both sides of the River.

A successful economic redevelopment of Lower Manhattan requires the replacement and enhancement of transportation facilities that were lost or damaged on September 11, 2001. As described above, current plans, which are independent of this Project, call for the rehabilitation of vehicular and transit facilities throughout Lower Manhattan. Although these projects would improve access to and from the area for those commuting to and from New Jersey, none offers the direct and high-capacity linkage that can be served by PATH and the Permanent WTC PATH Terminal.

In a survey of 25 executives of major employers located in Lower Manhattan, a Permanent WTC PATH Terminal was identified as "extremely" important to the future economic health of Lower Manhattan (Alliance for Downtown New York, Inc., April 2003). As described below, 15

percent of Lower Manhattan's workforce lived in New Jersey prior to September 11, 2001 and the WTC PATH Terminal was the busiest of downtown's transit stations. It is expected that as the WTC and other sites are developed with future commercial workers, a similar pool of new employees would be drawn from New Jersey. Thus, a restored and enhanced WTC PATH facility would be needed to accommodate newly generated demand for employees and their commute to and from Lower Manhattan offices. If such a facility were not provided, the full potential of Lower Manhattan's revitalization may never be realized.

RIDERSHIP GROWTH

Lower Manhattan is a vital component of the New York economy. It is second only to Midtown Manhattan in terms of gross floor area of office space, and it is a growing residential neighborhood and retail destination.

Prior to September 11, 2001, businesses in the area south of Canal Street employed more than 388,000 workers. Based on 1990 reverse journey-to-work data prepared by the U.S. Bureau of the Census, approximately 15 percent of Lower Manhattan's workforce commuted from west of the Hudson River and, as with the majority of workers in Lower Manhattan, transit was their predominant mode of travel.

The terrorist attacks resulted in the loss of 12 million square feet of office space and 500,000 square feet of retail space south of Canal Street. This physical loss of space coupled with a general economic downturn resulted in a reduction of 80,000 jobs in Lower Manhattan. As described above, LMDC and PANYNJ are planning for the redevelopment of the WTC site, meaning that most of the office space damaged or destroyed on September 11, 2001 will be replaced by 2015. In addition, a memorial, cultural facilities, and retail space will be constructed on the WTC site that will attract visitors in addition to the anticipated return of office workers.

Prior to September 11, 2001, proposals had been made for the continued development of vacant or underutilized sites in Lower Manhattan with various office, retail, and residential projects. These projects combined with the anticipated return of workers to the area would increase the future demand for transportation infrastructure.

It is estimated that PATH's daily ridership at the WTC would be 175,000 by 2025, which would exceed the capacity of the temporary station. Therefore, without this project, the PATH system cannot adequately support the planned redevelopment of the WTC and the overall revitalization of Lower Manhattan.

COMMUTING TO LOWER MANHATTAN WITHOUT PATH

As described above, the WTC PATH Terminal was the gateway to Lower Manhattan for some 67,000 daily commuters. It was among the most heavily used transit facilities in the area, and it offered critical connections to destinations within downtown as well as NYCT subway service for access to other parts of New York City.

Immediately following September 11, 2001, commuters formerly using PATH's WTC lines were forced to seek other routes or modes of travel to reach destinations in Lower Manhattan. As a result, there were substantial ridership increases on Trans-Hudson ferries, uptown PATH lines, and NJ Transit commuter rail. Although these modes enable commuters to reach Lower Manhattan, they do not have the capacity or the flexibility to serve as a long-term alternative to a Permanent WTC PATH Terminal.

TRANS-HUDSON FERRIES

Following the terrorist attacks, demand for ferry service between New Jersey and Lower Manhattan increased by more than 100 percent. Ferry operators rushed to respond by implementing increased peak hour service and new routes. Although ferries served as an important interim mode of travel for Lower Manhattan's commuters, they would not serve long-term travel needs between New Jersey and Lower Manhattan:

- Ferries have a much lower capacity than heavy-rail. Thus, numerous additional boats and services would be required to accommodate the anticipated future transit demand to and from Lower Manhattan.
- Ferries to Lower Manhattan must dock along the Hudson or East Rivers. While the location of ferry terminals may be convenient for those who work along Water Street and at the World Financial Center, others must walk much farther to reach interior destinations than was required with PATH service. Furthermore, most ferry passengers must transfer to one or more additional modes within New Jersey during their commute. Additional transfers and longer walks within Lower Manhattan increase the overall commute time and, thereby, decrease the attractiveness of this mode of travel.
- Ferry service is limited during inclement weather. During heavy rain storms or when the waters of the Hudson are icy, the ability to maintain ferry service is constrained.

UPTOWN PATH LINES

Following the destruction of the WTC PATH Terminal on September 11, 2001, many commuters diverted to PATH's Midtown routes. Once in Manhattan, these passengers would connect to NYCT subways to reach destinations in Lower Manhattan. As a result, ridership at PATH's Christopher and 9th Street Stations doubled during peak periods.

Both the Christopher and 9th Street Stations have a limited capacity. Platforms are narrow, there is only one point of access/egress, and fare zones are too small to serve large numbers of commuters. To immediately address these problems, PANYNJ had to limit station access during certain hours. Although upgrades are planned for these stations (see Chapter 8, Section A, "PATH"), they will not have adequate capacity to support general PATH system growth if a Permanent WTC PATH Terminal is not constructed.

NEW JERSEY TRANSIT COMMUTER RAIL

Following the terrorist attacks, ridership on NJ Transit commuter rail increased by approximately 30 percent, requiring additional trains on its routes serving New York's Pennsylvania Station. Although this additional capacity could accommodate the demand generated by the absence of PATH service to Lower Manhattan, it precluded certain service enhancements planned for this system.

For example, NJ Transit recently completed construction of the Secaucus Transfer, which provides a link between the Northeast Corridor line serving Pennsylvania Station, and the Main and Bergen County lines that serve Hoboken. Prior to its opening, passengers on several NJ Transit commuter rail lines would travel to Hoboken and then connect to PATH trains or ferries to access Midtown Manhattan. With the Secaucus Transfer, these passengers can now connect to Penn Station-bound commuter trains, resulting in a shorter commute time. Although the project was completed in summer of 2003, its full opening was delayed until temporary PATH service

was restored. NJ Transit could not support the increased ridership associated both with diverted PATH passengers and the Secaucus Transfer. If PATH service is not permanently restored to Lower Manhattan, it is expected that capacity constraints would exist on NJ Transit, thereby reducing the utility of the Secaucus Transfer and potentially limiting options for future system improvements.

Furthermore, NJ Transit and Amtrak share the rail lines that traverse the Hudson River between New Jersey and Lower Manhattan. Although a second Hudson River Tunnel is currently being studied, the interim expansion of the NJ Transit system is limited by the capacity of the single rail tunnel. Thus, if permanent PATH service is not restored to Lower Manhattan, there may not be additional capacity to support passengers that would be diverted to commuter rail.

LIMITATIONS OF TEMPORARY PATH SERVICE

To expedite the restoration of PATH service to Lower Manhattan, PANYNJ designed and built, on a fast-track basis, a temporary station. The temporary station was a commitment to restore the facilities damaged by the terrorist attacks and it was determined to be a catalyst to restore and redevelop Lower Manhattan by providing commuter service from west of the Hudson River. To ensure the speedy restoration of PATH service, the temporary station was constructed in essentially the same location as the pre-September 11, 2001 Terminal. This allowed PANYNJ to reuse certain infrastructure elements including the 1 and 9 underpass, portions of the retail concourse, and the NYCT subway station connections that remained on the WTC site. Furthermore, design documents could be advanced more quickly since track and platform configurations and other station elements could be constructed based on pre-September 11, 2001 plans. However, to achieve this commitment within two years after the attacks, PANYNJ compromised certain elements of the pre-September 11, 2001 Terminal with regard to operational capacity, service amenities, and pedestrian connections.

Because PANYNJ could use as-built plans from the pre-September 11, 2001 Terminal to design and construct the temporary station, extensive survey work was not needed. Designers could lock in the station and track configuration both horizontally and vertically. As such, steel detailing could be expedited and steel sizing accelerated. Since it was intended as a temporary station, platforms were designed to be removed and not integral to the platform walls; interior drainage was less than desired since only the outer bay of the station has interior drains; and, roof insulation was minimal since it was an outdoor facility.

The temporary station has 8-car platforms as compared to the 10-car platforms that were part of the pre-September 11, 2001 Terminal, resulting in 20 percent less operational capacity. Prior to September 11, 2001, PANYNJ was studying the extension of stations along its Newark-WTC route to provide for 10-car train service. These improvements were in response to ridership levels that were reaching maximum capacity on this route during peak periods.

Some of the infrastructure elements within the station have a limited service life. The vertical elements, while ADA-compliant, do not provide a sufficient level of service to accommodate future demand. Escalators from the platform to the mezzanine level and from mezzanine level to the NYCT 1 and 9 subway line underpass were not provided. The station's design does not allow for new construction above, as planned for the WTC redevelopment, nor can it easily support connections to future buildings on the WTC site or other off-site destinations.

To expedite service restoration, the temporary station's tracks and platforms are located outdoors in the WTC "bathtub." Weather protection is provided, but the station is not fully enclosed and

is not climate-controlled. Local radiant heating is provided in waiting areas, but many portions of the station complex are not heated during winter months or cooled during summer months. As noted previously, the pre-September 11, 2001 Terminal was fully climate-controlled.

The temporary station includes security and fire protection equipment, but advanced passenger amenities are not provided. The station is ADA-compliant, but its configuration requires four separate elevator rides to reach street level. Emergency exits are provided, but they lead passengers either to Church Street or to the WTC bathtub area with access to the street via the temporary access ramp and a temporary stairway to West Street.

Because construction of the WTC site is ongoing, pedestrian access to the temporary station is limited as compared to the pre-September 11, 2001 Terminal. All patrons enter and exit at street level near the intersection of Church and Fulton Streets at the eastern boundary of the WTC site. Thus, patrons traveling to the World Financial Center must double-back along Vesey or Liberty Street. The temporary station has connections to NYCT's E, R, and W lines, but access to 1 and 9 trains is not available because NYCT has not yet reopened its Cortlandt Street Station. As such, two fewer subways are served compared to pre-September 11, 2001 conditions.

D. GOALS AND OBJECTIVES

The Permanent WTC PATH Terminal would be a full-service, regional transportation hub that would be coordinated with existing and future transportation infrastructure, WTC site development, and the surrounding area. The Project is needed to reestablish and enhance transportation facilities and infrastructure that existed at the WTC complex prior to September 11, 2001 and to ensure the long-term accessibility and economic vitality of Lower Manhattan.

EFFECTIVELY RESTORE LONG-TERM PATH SERVICE BETWEEN NEW JERSEY AND LOWER MANHATTAN

The Project should provide for a facility that maintains a direct transit connection between New Jersey and Lower Manhattan. It should serve as a long-term, high-capacity facility with enhanced amenities as compared to the pre-September 11, 2001 WTC PATH Terminal. To successfully address this goal, the Project must meet the following objectives:

- Accommodate pre-September 11, 2001 PATH ridership;
- Provide for additional capacity at the Terminal to support ridership growth;
- Provide for modern station design with ADA-accessibility, climate control, and station security; and
- Minimize disruption to temporary PATH service during construction.

ESTABLISH AN INTERMODAL TRANSPORTATION FACILITY IN LOWER MANHATTAN

The Project should enhance transportation connections to, from, and within Lower Manhattan as compared to pre-September 11, 2001 conditions. The opportunity to rebuild a PATH facility should take advantage of connections to existing and future transit infrastructure and should allow for improved at-grade and below-grade pedestrian connections as compared to the pre-September 11, 2001 and temporary PATH facilities. To successfully address this goal, the Project must meet the following objectives:

- Improve street-level visibility and access;
- Provide for adequate and state-of-the-art pedestrian circulation within the facility; and
- Provide for connections to NYCT subways and other major origination and destination points.

PLAN AND CONSTRUCT A TERMINAL THAT WOULD SUPPORT THE REDEVELOPMENT OF LOWER MANHATTAN

The Project should support the physical and economic recovery of Lower Manhattan, including proposals for the reconstruction or rehabilitation of other transportation infrastructure, redevelopment of the WTC site, and construction and occupation of other off-site projects, all of which are undergoing separate environmental reviews, as detailed above. To successfully address this goal, the Project must meet the following objectives:

- Construct a facility that is coordinated with the master plan for the WTC site;
- Provide for future connections to WTC buildings and functions, including the proposed memorial;
- Coordinate PATH facilities with other sub-grade uses at the WTC site; and
- Plan and coordinate PATH elements with proposals for the reconstruction of Route 9A, the Fulton Street Transit Center, and other off-site development.

MINIMIZE ADVERSE IMPACTS TO THE ENVIRONMENT

The construction and operation of the Project should not, to the extent possible, adversely effect the local and regional environment in the short-term or long-term. The desired alternative would not only minimize adverse effects but would also provide for the greatest positive benefits to both the build and natural environment. To successfully address this goal, the Project must meet the following objectives:

- Reuse existing infrastructure to the extent possible;
- Provide for efficient and environmentally friendly construction techniques;
- Minimize disruption to PATH and NYCT subway service during construction; and
- Provide for "green" and sustainable design. ✷

A. INTRODUCTION

As described in Chapter 1, "Purpose and Need," the Permanent World Trade Center (WTC) PATH Terminal is one of four projects proposed for funding under the $4.55-billion Lower Manhattan Transportation Recovery Effort. The federal government is also proposing to fund the Fulton Street Transit Center (FSTC), South Ferry Terminal, and Route 9A Project in addition to the Permanent WTC PATH Terminal. These other transportation projects are being sponsored and evaluated independent of the Permanent WTC PATH Terminal. The federal government, through the U.S. Department of Housing and Urban Development (HUD), is also proposing to fund the Lower Manhattan Development Corporation's (LMDC) WTC Memorial and Redevelopment Plan. Although the WTC Memorial and Redevelopment Plan and the Permanent WTC PATH Terminal would both occupy spaces on the WTC site, these projects are considered independent actions under the National Environmental Policy Act (NEPA) process and are therefore being evaluated and assessed in separate Environmental Impact Statements (EISs).

Project Alternatives for a Permanent World Trade Center (WTC) PATH Terminal were identified as part of early planning studies conducted by the Port Authority of New York and New Jersey (PANYNJ) following the terrorist attacks of September 11, 2001, and throughout this environmental review process. This chapter describes the process for developing Project Alternatives, including a discussion of the overall alternatives development process, a description of the Preferred Alternative, and a review of alternatives considered and eliminated from further study.

Three Project Alternatives were advanced through the alternatives development process for detailed study in the Draft EIS (DEIS), as follows:

- No Action Alternative
- Terminal without Liberty Plaza Connection Alternative
- Terminal with Liberty Plaza Connection Alternative

Since publication of the DEIS, PANYNJ and FTA have selected the Terminal without a Liberty Plaza Connection as the Preferred Alternative for a Permanent WTC PATH Terminal. This alternative was selected after careful consideration of the public comments received during the public review process for the DEIS. Not only would the Preferred Alternative meet the goals and objectives of the project, but it would also provide for substantial improvements over the pre-September 11, 2001 WTC PATH Terminal and the temporary WTC PATH station.

As described in the DEIS, the design of the Permanent WTC PATH Terminal is being closely coordinated with the other Lower Manhattan recovery efforts described above. To anticipate potential modifications to this Project that may be necessary to coordinate with these independent actions, the DEIS identified design options for components of the Terminal. Specifically, the DEIS described options for the coordination of the Terminal's construction with other uses on the WTC site, the location of ventilation structures, the cooling system to be

employed, and the pedestrian connection across Route 9A. Since publication of the DEIS, PANYNJ has advanced the Terminal's design and has determined that these design options are no longer needed. As such, this Final EIS (FEIS) identifies the options selected as part of the Preferred Alternative and describes the options eliminated from further consideration.

This chapter in conjunction with Chapter 3, "Construction Methods and Materials," also describes the framework for the assessments of environmental effects presented in the technical chapters that follow. This discussion includes the development of baseline conditions for analysis, assumptions applied in the analysis of the No Action and Preferred Alternatives, and the approach to studying cumulative effects. This framework also presents the Environmental Performance Commitments (EPCs) and environmentally friendly "green" measures that would be incorporated into the design and construction of the Preferred Alternative to avoid or minimize potential adverse impacts to the environment.

B. ALTERNATIVES DEVELOPMENT PROCESS

LOCATIONS FEASIBILITY ANALYSIS

While restoring temporary PATH service to Lower Manhattan as described in Chapter 1, "Purpose and Need," PANYNJ began planning for a permanent facility, including tracks, platforms, mezzanines, pedestrian concourses, and a terminal building on or near the WTC site. Not only did PANYNJ intend to restore the capacity and connectivity that existed within the pre-September 11, 2001 WTC PATH Terminal but also wished to enhance pedestrian connections through the site and adjacent properties and to create a world-class transportation hub for Lower Manhattan. To that end, PANYNJ conducted a detailed analysis of alternatives for transit service between New Jersey and Lower Manhattan. The process that was undertaken is described below.

LOCATIONS FEASIBILITY ANALYSIS FRAMEWORK

Planning Constraints

The PATH system operated between New Jersey and Lower Manhattan for almost 100 years prior to the September 11, 2001 terrorist attacks. Thus, a substantial infrastructure had been built to support this high-capacity, heavy-rail service. Although the attacks and their resultant damage severely hindered operations, PATH was able to maintain service at all but two of its stations (Exchange Place and WTC). Furthermore, PATH's Hudson River tunnels between Exchange Place and Lower Manhattan were damaged by flooding but were determined to be structurally sound. New York City Transit's (NYCT) 1 and 9 line, which traverses the WTC site, was also damaged but was reconstructed on an expedited schedule to restore service within one year of the attacks. In planning for long-term transit service between New Jersey and Lower Manhattan, PANYNJ made an early decision not to preclude operations on portions of the PATH and NYCT systems that remained intact. To that end, PANYNJ's planning was constrained by four important considerations as described in Table 2-1.

Given these constraints, the only reasonable alternatives would be alternate locations for a Lower Manhattan PATH terminal.

Table 2-1
Locations Feasibility Planning Constraints

Planning Constraint	Description
Re-use Hudson River tunnels	Construction of new Hudson River tunnels would be time-consuming and expensive and may have potential adverse effects on the environment. New tunnels would also require right-of-way that may be outside current PANYNJ jurisdiction. Thus, it was determined that future Trans-Hudson service should use the existing tunnels between Exchange Place and the WTC site.
Maintain a heavy-rail system	Use of the Hudson River tunnels limits the type of service that can be provided because PATH's infrastructure, fleet, and support systems would not be easily adapted to other types of service. The introduction of alternative modes would severely disrupt the remainder of the PATH system.
Connect to existing tunnel projections	Use of the Hudson River tunnels requires connections to the PATH projections at the WTC site, which constrains the alignment within Lower Manhattan. New links to these projections must comply with PATH's systemwide grade and curvature specifications.
Maintain NYCT's 1 and 9 train alignment	Any PATH infrastructure that penetrates through NYCT's 1 and 9 line must be below the subway tracks. Such plans would need to consider the height, depth, and width of these protrusions and their potential effects on subway service.

Planning Guidelines

In planning for a permanent terminal, PANYNJ not only desired to restore the facility that existed before September 11, 2001 but also strived to improve and enhance service to Lower Manhattan. Chapter 1, "Purpose and Need", outlined the goals and objectives for the Project. In order to fully assess location options for a Terminal, these goals and objectives were refined into more specific planning guidelines so as to weigh various benefits and potential shortfalls of the locations being considered. These planning guidelines are described in Table 2-2.

Location Options

Given the planning constraints described above, PANYNJ identified four sites of an appropriate size and configuration for a permanent PATH terminal. These locations are shown in Figure 2-1 and are described below.

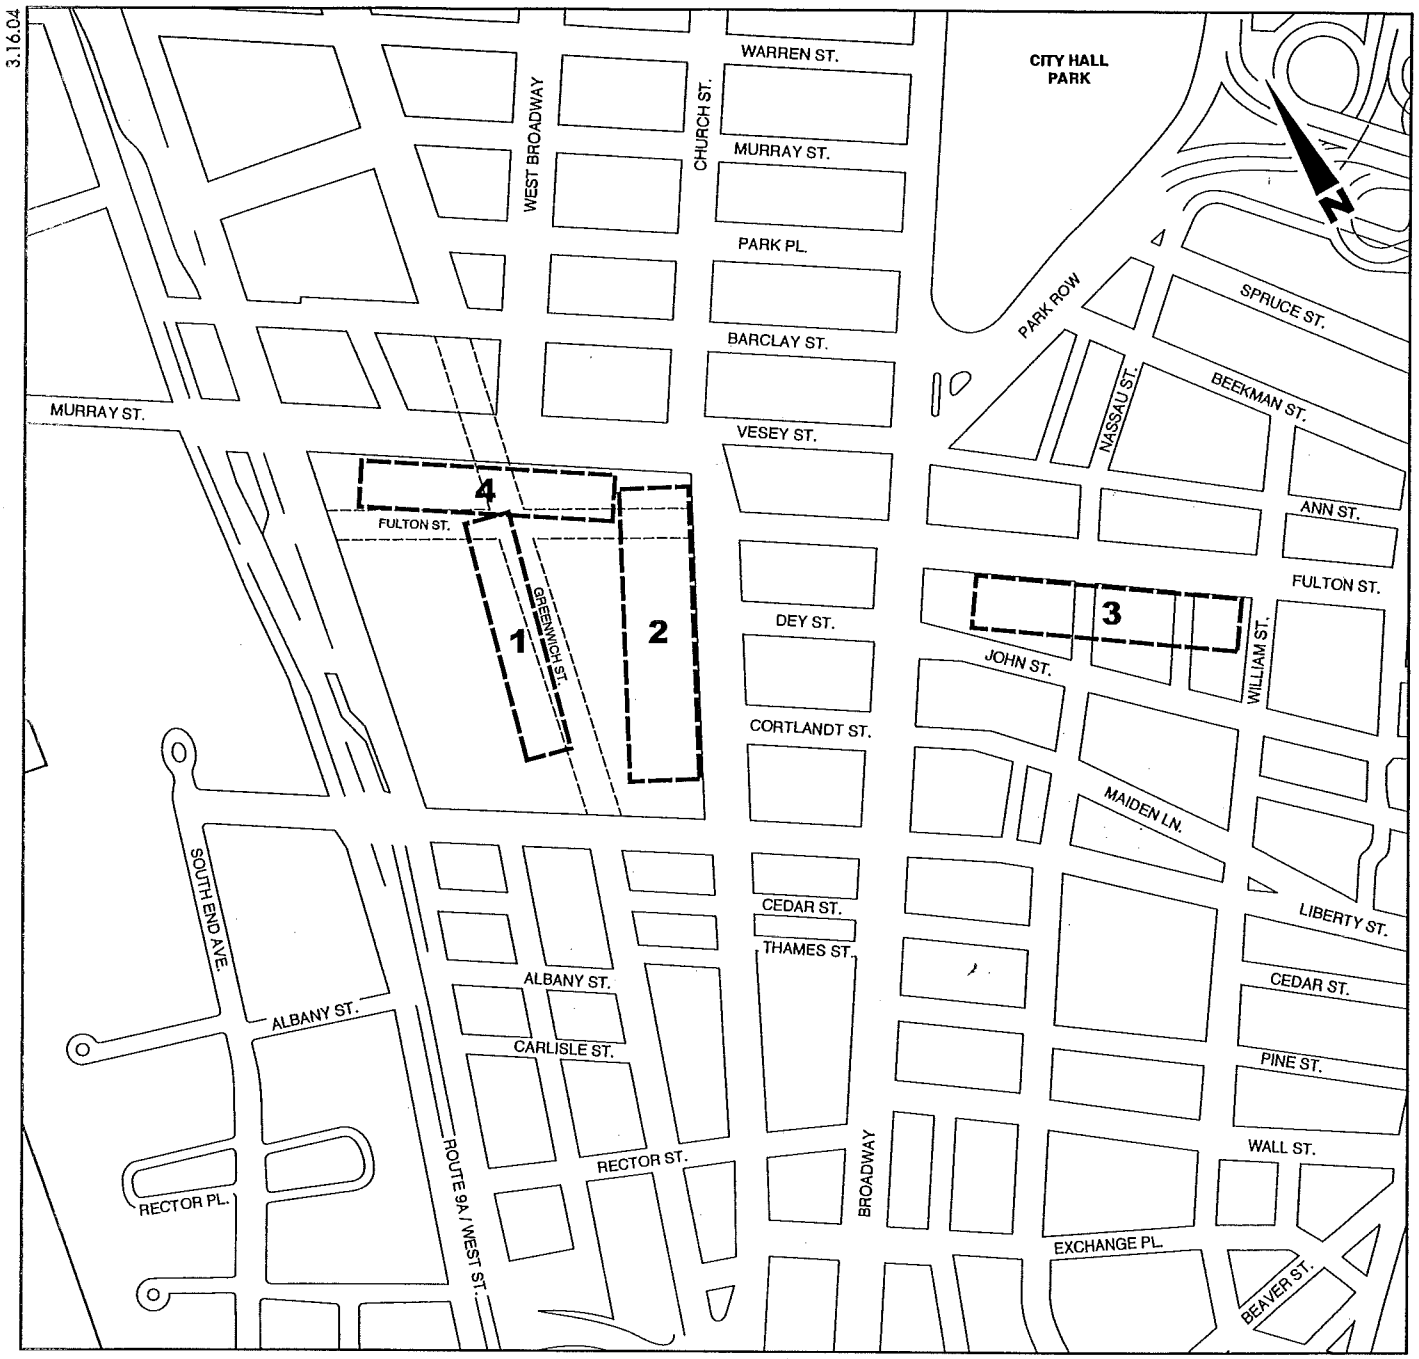
- Location 1, WTC "Bathtub": The WTC "Bathtub" option would restore service in the location of the pre-September 11, 2001 WTC Terminal by building the tracks, platforms, and mezzanines in the same location as the temporary PATH station. The platform level would have a north-south configuration with a loop track arrangement. There would be five tracks and three 10-car platforms. A terminal building would be constructed at street level, directly above the platforms and mezzanine, with access from Greenwich Street, and pedestrian concourses would allow for all-weather access to the World Financial Center, future buildings on the WTC site, NYCT's Fulton Street Transit Center, and NYCT's WTC and Cortlandt Street subway stations.

  Location 2, Church Street: The Church Street option would be a new facility in the approximate location of the original Hudson and Manhattan (H&M) Terminal, along the west side of Church Street between approximately Fulton and Cortland Streets. It would be a loop station and would have a north-south orientation on the eastern portion of the WTC site between Church and Greenwich Streets. The proposed plan would be for five tracks and five 10-car platforms. Four of the five platforms would accommodate separate boarding and alighting operations. A terminal building would be constructed above the platforms and mezzanine and would have street-level access from Church Street. This location would also provide for pedestrian concourses with all-weather access to the World Financial Center, future buildings on the WTC site, NYCT's Fulton Street Transit Center, and NYCT's WTC and Cortlandt Street subway stations.

Table 2-2
Locations Feasibility Planning Guidelines

Planning Objective	Description
Create a world-class, transportation facility in Lower Manhattan	The new PATH facility should be integrated with existing and proposed transportation infrastructure and other uses but should also have a significant presence in Lower Manhattan. A desirable location would allow for integration of sub-grade pedestrian connections with other facilities and for an above-grade terminal building that enhances the overall experience of PATH customers.
Support the redevelopment of Lower Manhattan	The permanent terminal should support the redevelopment of Lower Manhattan and its economic recovery. Although PATH is critical to Lower Manhattan's transportation infrastructure, a permanent terminal should not preclude other development on or off the WTC site. A desirable location would allow for the restoration and enhancement of PATH service but would not hinder other redevelopment efforts. The objective is to maximize space on the WTC site for redevelopment.
Provide for improved pedestrian connections	The permanent terminal should provide pedestrian connections to the facilities previously served by PATH, including NYCT's WTC (E) and Cortlandt Street (1 and 9; R and W) subway stations, Battery Park City, World Financial Center, and future buildings on the WTC site. The terminal should also connect to NYCT"s Fulton Street Transit Center (2, 3, 4, 5, A, C, J, M, and Z subway lines) and provide for concourses to serve other destinations based on pedestrian demand in Lower Manhattan.
Minimize impacts to temporary PATH service during construction	To avoid the commutation problems that existed immediately following September 11, 2001, PANYNJ desires not to disrupt weekday, peak-period service at the temporary WTC PATH station during construction of a permanent terminal.
Minimize impacts to the local environment during and after construction	The blocks immediately adjacent to the WTC site contain some of the area's largest office buildings as well as historic structures, which would be sensitive to disruption, displacement, underpinning, or other construction activities associated with a permanent terminal. Thus, any option that would directly displace businesses would not be desired.
Enhance pre-September 11, 2001 PATH operations	The permanent terminal should maintain the maximum operation of the pre-September 11, 2001 Terminal of 30 trains per hour. The terminal should also reduce the cross-flow conflicts that existed previously. Although 5 platforms and 5 tracks would virtually eliminate cross-flow, it was determined that 4 platforms would greatly improve conditions as compared to pre-September 11, 2001.
Support 10-car PATH trains	PANYNJ plans to widen platforms on PATH's Newark-WTC route to support 10-car trains. Thus, a future terminal should not preclude this long-term operating plan.
Provide for advanced security	To prevent future incidents at the WTC site, including the PATH terminal, PANYNJ, LMDC, Metropolitan Transportation Authority (MTA), and New York State Department of Transportation (NYSDOT) would provide for integrated, enhanced, and state-of-the-art security measures within the design of the individual projects. As such, the physical design of a permanent terminal and the WTC site must provide for adequate facilities to support security measures such as surveillance, structural hardening, and truck checkpoints for the protection of Lower Manhattan.
Re-use existing PATH right-of-ways	A location outside the WTC site would require property acquisition and potential demolition of existing structures, which may increase the cost of the project, increase the duration of construction, and may have potential adverse impacts on the local environment. PANYNJ would be less inclined to pursue a location needing additional right-of-way.
Minimize construction cost and duration	While working to pursue the other planning goals, PANYNJ would desire a location that provides the greatest benefits at a reasonable cost and within a reasonable construction timeframe.

- Location 3, Broadway-Nassau: The Broadway-Nassau option would be a new facility located east of the WTC site under Dey Street and beneath NYCT's Fulton Street Transit Center. It would be a stub-end station, meaning that conductors and engineers would need to change positions within the train to continue service in the reverse direction. The station would have five tracks and five 10-car platforms. It would be integrated with the Fulton Street Transit Center and would have street-level access from Broadway, Fulton Street, and John Street. Convenient, below-grade access to NYCT's 2, 3, 4, 5, A, C, J, M, and Z trains



PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure 2-1
Alternative Locations

would be provided. Connections to NYCT's R and W trains would be via a newly constructed concourse under Dey Street. There may also be all-weather connections to the World Financial Center or the future buildings on the WTC site.

- Location 4, Vesey Street: The Vesey Street option would be located in the WTC "Bathtub" along Vesey Street. It would have an east-west orientation and would form a loop with the Hudson River tunnels. It would have five tracks and five 10-car platforms. A terminal building would be constructed immediately above the platforms and mezzanines at street level with pedestrian access from Vesey and Fulton Streets. Pedestrian concourses would allow for all-weather access to the World Financial Center, future buildings on the WTC site, and NYCT's 1, 2, 3, 9, A, C, E, R and W subway lines with a possible connection to the Fulton Street Transit Center.

LOCATIONS EVALUATION

Fatal Flaws Analysis

Before advancing any design options, PANYNJ conducted an initial screening of the four sites to determine if any were seriously flawed. It was determined that any location, which 1) would not provide for adequate PATH operations, 2) would fully disrupt temporary PATH service, or 3) require major property acquisition and/or demolition of active buildings, would not be consistent with the overall goals and objectives for the Project identified in Chapter 1, "Purpose and Need". Using the planning guidelines described above, PANYNJ established that two locations would not satisfy the current and future needs of PATH customers as described below.

- Location 1, WTC "Bathtub": Location 1 would allow for a maximum operating capacity of 30 trains per hour. It would require some disruption to temporary PATH operations when portions of the station are upgraded during construction. However, careful staging would maintain service during peak periods. Since the terminal would be located on the WTC site, property acquisition and demolition of buildings would not be required. Furthermore, potential business disruption would be minimal since most construction activities would occur off-street. Thus, Location 1 was carried forward for further study.

- Location 2, Church Street, would allow for a maximum operating capacity of 30 trains per hour. It would require minor disruption to temporary PATH operations when its tracks are connected to the Hudson River tunnels, but service could be maintained during peak periods. Since the terminal would be located on the WTC site, property acquisition and demolition of active buildings would not be required. Furthermore, potential business disruption would be minimal since most construction activities would occur off-street. Thus, Location 2 was carried forward for further study.

- Location 3, Broadway-Nassau, would allow for a maximum operating capacity of 20 trains per hour, which is below the goal of 30 trains per hour. It would require full closure of the temporary PATH station for several months during construction as the tracks leading to the terminal would cross those of the temporary station such that the temporary tracks would need to be removed. The terminal's construction would require the acquisition of property and certain buildings would need to be demolished. Furthermore, above- and below-ground construction activities would likely require street closures. This could result in direct displacement of businesses in the vicinity of the proposed terminal. Because Location 3 failed to meet the operational requirements of PATH, it was considered fatally flawed.

- Location 4, Vesey Street, would have a maximum operating capacity of 30 trains per hour. However, it would require full closure of the temporary PATH station during construction because the tracks and platforms of the terminal would require the removal of infrastructure from the temporary station. Since the terminal would be located on the WTC site, property acquisition and demolition of buildings would not be required, and potential business disruption would be minimal. Because Location 4 would preclude temporary PATH service during construction, it was considered fatally flawed.

Detailed Screening Analysis

PANYNJ conducted further analysis for Location 1 (WTC "Bathtub") and Location 2 (Church Street) to evaluate their consistency with the long-range planning guidelines described above. Since these locations were similar in terms of many general goals, the detailed screening focused on specific differences in terms of their construction, long-term operations, and compatibility with redevelopment efforts for the WTC site.

Construction

PANYNJ prepared cost estimates and construction schedules for the development of a permanent terminal at Locations 1 and 2 based on preliminary engineering. This analysis showed that the Church Street option would cost 20 to 25 percent more and would require 7 to 10 percent more time to construct than the WTC "Bathtub" option.

The differences in construction cost and duration were mainly attributed to the site preparation and structural underpinning required for the Church Street option. Because the WTC "Bathtub" option is located in the area of the site that was fully cleared during recovery efforts, little site preparation would be necessary. The Church Street option is located on a portion of the site that retains five sub-grade levels (two basement levels of the former WTC complex and the three levels of the old H&M Terminal). These structures would need to be demolished and debris removed. Furthermore, a new slurry wall would need to be constructed east of the NYCT 1 and 9 subway line to excavate new PATH right-of-way between Church, Greenwich, Vesey, and Liberty Streets. Thus, front-end construction activities for the Church Street option would be longer and more costly than for the WTC "Bathtub" location.

The WTC "Bathtub" location would be constructed within and above the temporary station, requiring a complex staging plan to maintain PATH service. Thus, certain activities that could normally be implemented in a single phase would be spread over multiple stages of construction. Because the majority of the Church Street option would not directly affect temporary PATH operations, a less complicated construction phasing plan could be implemented, resulting in a more efficient construction process than with the WTC "Bathtub" option.

The Church Street option requires new track and tunnels beneath the 1 and 9 line; therefore, extensive underpinning of NYCT's infrastructure would be necessary. These activities would add to the project cost, require extensive staging and coordination to minimize disruption to subway service, and prolong the construction schedule. The WTC "Bathtub" option would require underpinning of NYCT's 1 and 9 subway line for platform and concourse construction, but such activities would be far less intensive than with the Church Street option.

Operations

Both locations would provide for improved operations as compared to the pre-September 11, 2001 Terminal. However, each would offer certain operating advantages.

The Church Street option would have two additional platforms as compared to the WTC "Bathtub" location, which would facilitate dedicated loading and unloading activities during peak periods and an extremely efficient platform circulation. The three-platform configuration of the WTC "Bathtub" location could not support dedicated loading and unloading. Although the Church Street location would have superior circulation as compared to the WTC "Bathtub" option, the maximum throughput of both stations would be 30 trains per hour.

The configuration of the WTC "Bathtub" location allows for better vertical circulation than the Church Street option. Because vertical elements could be arranged to allow for a diagonal ascension to street level, the WTC "Bathtub" location would facilitate passenger movements from platform level to concourse/street level in the desired direction of travel. Since space for the Church Street option is more constrained, vertical elements would be stacked and arranged in a scissor-style such that some passengers would double-back within the station complex to maneuver between platform and concourse/street level. Thus, the vertical circulation of the WTC "Bathtub" option would be more efficient than the Church Street location.

Each location offers relative proximity to certain destinations in Lower Manhattan. The Church Street option would be approximately 300 feet east of the WTC "Bathtub" location; thus, it would be one block closer to the Financial District, the Civic Center, the Fulton Street Transit Center, and NYCT's Cortlandt Street (R and W) and WTC (E) subway stations. The WTC "Bathtub" location would be closer to Battery Park City and the World Financial Center. Each location, therefore, offers advantages for certain riders.

Compatibility with WTC Redevelopment Efforts

The Church Street or WTC "Bathtub" PATH terminal would be one component of the redevelopment on the WTC site. Any future terminal must not preclude redevelopment efforts, and the most desirable location would allow planners to achieve the maximum programming of other uses. Furthermore, the terminal must allow for the enhanced security measures that would need to be incorporated into the site's design so as to not limit the ability of site developers to provide for enhancements as compared to pre-September 11, 2001 conditions.

Because infrastructure is required throughout the site to support all of the redevelopment components, it was determined that the first four levels of the WTC from the bathtub floor would be dedicated to transportation, utilities, internal circulation elements, and building support. These levels would also contain the tracks, platforms, and mezzanines for PATH. Areas above the fourth level would follow a master plan for the site with programmed spaces for a memorial, cultural facilities, open space, and commercial uses.

All infrastructure associated with the WTC "Bathtub" option would be on the western portion of the site, freeing the eastern portion of PATH elements. This would allow maximum flexibility for commercial development and the incorporation of mechanical, security, and building servicing infrastructure required for such development. Furthermore, secured loading and servicing as well as large retail spaces could be made available in the below-grade spaces on the eastern portion of the WTC site. With the ability to provide multi-level retail spaces on the eastern portion of the site, major anchor tenants could be sought such as "big-box" retailers or department stores, which would restore and enhance the overall retail composition of Lower Manhattan. Because much of the rest of Lower Manhattan is fully developed, it would be difficult to provide adequate spaces for such retailers off-site. The above-grade portions of the WTC "Bathtub" option would be within the area of a proposed memorial, including its headhouse.

The Church Street option would have PATH elements throughout the WTC site. While the western portion would only contain the tracks and ancillary facilities, the platforms, mezzanines, concourses, and terminal building would be located wholly within the eastern portion. Given the "scissor-style" configuration of a Church Street terminal, safe passenger egress would require that the level of the terminal's tracks and platforms be higher than for the WTC "Bathtub" location. These below-grade spaces dedicated to PATH either would preclude or would require that retail, security and other support services are located elsewhere. Thus, loading areas and parking facilities would be located above grade or eliminated. If above-grade loading areas were needed, it is likely that they would be accessed from Greenwich Street because New York City guidelines typically disallow such activities from wide avenues such as Church Street. These trucking activities would not be sensitive to the memorial zone, which would be located opposite Greenwich Street. Furthermore, since above-grade loading would likely require that individual areas be provided in each of the offices towers, ground-level space would be lost and centralized security could not be provided. Based on preliminary programming for the WTC site, it is estimated that a total of approximately 15 to 25 percent of the potential on-site retail spaces would be lost under the Church Street location as compared to the WTC "Bathtub" option.

Construction of commercial towers above a PATH terminal at the Church Street location would require advanced engineering and a longer schedule to complete. Certain structural elements within the PATH terminal would be required to support a commercial overbuild, which would reduce the flexibility of the station's design and the flexibility of the above-grade development. Furthermore, other site uses within the eastern portion of the site could not be constructed until PATH elements are completed; thus, the Church Street location may result in an extended timeframe for the overall redevelopment of the WTC site.

Analysis Results

Table 2-3 compares the results of the detailed screening analysis. Location 1 was determined to be more desirable in terms of construction because it would be less expensive with slightly shorter duration. Although intensive coordination would be needed to maintain temporary PATH service, the WTC "Bathtub" location would allow for simultaneous construction of other projects on the WTC site. Thus, the schedule for the overall site redevelopment may be reduced.

The Church Street option would allow for superior platform circulation as compared to the WTC "Bathtub" option; however, vertical circulation would be more difficult. Both locations would have all-weather connections to NYCT subways, but the Church Street option would be closer to most of the existing stations. It would also be one block closer to developments within the Civic Center and the Financial District. However, the WTC "Bathtub" location would have better proximity to the World Financial Center and Battery Park City.

Generally, the WTC "Bathtub" option would be more compatible with proposed uses on the WTC site. Certain above-grade portions would need to be integrated with the future memorial. However, this location would allow for the maximum development potential of other uses, which would enhance the economic recovery of Lower Manhattan. The Church Street option would not require above-grade structures within the area of the memorial, but it would hinder sub-grade and above-grade commercial development on other portions of the site. Furthermore, the Church Street option would have contextual impacts to the memorial since building servicing, such as truck loading and security would likely be at street level, and it is probable that spaces beneath the memorial would be needed to support other buildings on the site.

Table 2-3
Locations Feasibility Detailed Screening Analysis Results

Criteria	Location 1 WTC "Bathtub"	Location 2 Church Street
Construction		
Cost	30% to 35% less expensive	30% to 35% more expensive
Duration	7% to 10% shorter	7% to 10% longer
Constructability	Requires complex staging plan to avoid disruption to temporary PATH service	Requires extensive site preparation and underpinning of NYCT infrastructure
Operations		
Tracks	5	5
Platforms	3	5
Platform Cross-flow	Cross-flow conflicts on all platforms	Cross-flow conflicts on 1 platform
Vertical Circulation	Easily navigable	More complex with double-back movements to reach street level
Proximity to Civic Center	One block farther	One block closer
Proximity to Financial District	One block farther	One block closer
Proximity to World Financial Center and Battery Park City	One block closer	One block farther
Proximity to NYCT Cortlandt Street Station (1 and 9)	No difference	No difference
Proximity to NYCT Cortlandt Street Station (R and W)	One block farther	One block closer
Proximity to NYCT World Trade Center Station (E)	One block farther	One block closer
Proximity to Fulton Street Transit Center (2, 3, 4, 5, A, C, J, M, and Z)	One block farther	One block closer
Proximity to World Financial Center Ferry Terminal	One block closer	One block farther
Compatibility with WTC Redevelopment		
Compatibility with Memorial	Certain above-grade elements would be within the memorial zone; these facilities could be integrated into the memorial's design	Contextual effect if building servicing is moved to street level. Certain site elements may be located beneath the memorial.
Compatibility with Other Site Development	Allows for more flexibility in above-grade development and approximately 15% to 25% more on-site retail.	Requires spaces that could be programmed for commercial uses and reduces the flexibility of site planning and construction. Could result in a 15% to 25% reduction in retail space.
Compatibility with site infrastructure and security	Allows for sub-grade security checkpoints, building servicing, and goods delivery.	Requires at-grade building servicing and goods delivery; may preclude centralized security checkpoint.

The "Hybrid" Option

PANYNJ reviewed the results of the detailed screening analysis to determine locations for the permanent terminal to be evaluated further. Because PANYNJ recognized certain benefits of both options, a plan that would accommodate the advantages of both locations was developed. As the conceptual planning of the WTC site was advanced, it was determined that spaces between Greenwich and Church Streets could be made available for a PATH terminal, but there would not be sufficient below-grade space to accommodate new tracks and platforms along Church Street. Thus, PANYNJ proceeded with a plan that would maintain the tracks and platforms within the WTC "Bathtub" but would locate the major pedestrian connections and terminal building in the vicinity of Church Street. Table 2-4 compares the evaluation of this "hybrid" option to the WTC "Bathtub" and Church Street locations.

Table 2-4

Comparison of the WTC "Bathtub", Church Street, and "Hybrid" Locations

Criteria	Location 1 WTC "Bathtub"	Location 2 Church Street	"Hybrid" Location
Construction			
Cost	Lowest Cost	Medium Cost	Highest Cost
Duration	Shortest Duration	Longest Duration	Medium Duration
Constructability	Requires complex staging plan to avoid disruption to temporary PATH service	Requires extensive site preparation and underpinning of NYCT infrastructure	Requires site preparation on eastern portion and extensive coordination with temporary PATH
Operations			
Tracks	5	5	5
Platforms	3	5	4
Platform Loading and Unloading	Cross-flow conflicts could not be eliminated	Cross-flow conflicts could be eliminated on 4 of 5 platforms	Cross-flow conflicts could be eliminated on 1 of 4 platforms
Vertical Circulation	Easily navigable	More complex with some double-back movements to reach street level	Allows for improved vertical circulation over Location 2
Proximity to Civic Center	One block farther	One block closer	Same as Location 2
Proximity to Financial District	One block farther	One block closer	Same as Location 2
Proximity to World Financial Center and Battery Park City	One block closer	One block farther	Same as Location 1
Proximity to NYCT Cortlandt Street Station (1 and 9)	No difference	No difference	No difference
Proximity to NYCT Cortlandt Street Station (R and W)	One block farther	One block closer	Same as Location 2
Proximity to NYCT World Trade Center Station (E)	One block farther	One block closer	Same as Location 2
Proximity to Fulton Street Transit Center	One block farther	One block closer	Same as Location 2
Proximity to World Financial Center Ferry Terminal	One block closer	One block farther	Same as Location 1
Compatibility with WTC Redevelopment			
Compatibility with Memorial	Certain above-grade elements would be within the memorial zone; these facilities could be integrated into the memorial's design	Contextual effect if building servicing is moved to street level. Certain site elements may have to be located on the western portion of the site beneath the memorial	Limited effect but would have more below-grade infrastructure in WTC "Bathtub" than would Location 2
Compatibility with Other Site Development	Allows for more commercial development with greater flexibility	Requires spaces that could be programmed for commercial uses and reduces the flexibility of site security and planning	Allows use of below-grade levels for commercial uses, building servicing, and security but terminal building would occupy above-grade space

The "hybrid" option would be more costly and more difficult to construct than either the WTC "Bathtub" or the Church Street options. Because the construction of PATH elements would require site excavation on some of the eastern portion of the WTC site, the "hybrid" location would carry some of the construction costs that would be required for the Church Street location. However, construction of the PATH elements in both the eastern and western portions of the WTC site could be undertaken simultaneously; thus, the "hybrid" option would have shorter construction duration than the Church Street. Although the "hybrid" option does not have advantages over the WTC "Bathtub" or Church

Street locations in terms of construction, the long-term benefits were determined to outweigh these short-term construction issues.

The "hybrid" option would have the same number of tracks but one additional platform as compared to the WTC "Bathtub" location and therefore would be an improvement over PATH's pre-September 11, 2001 operations. Upon review and refinement with PATH's operations staff, it was determined that a four-platform configuration would be acceptable to accommodate long-term ridership demand. The "hybrid" option would be oriented similar to the pre-September 11, 2001 WTC PATH Terminal such that patrons would enter the station at platform level west of Greenwich Street but would travel eastward toward Church Street as they ascend through the complex. However, an additional egress in the westward direction would be provided to allow better connections to Battery Park City and the World Financial Center. Thus, in terms of its pedestrian connections, the "hybrid" location would combine the advantages of both the Church Street and the WTC "Bathtub" options.

The "hybrid" option gives greater flexibility for WTC site redevelopment than does the Church Street location but allows for the memorial zone to be freed of most, if not all, above-grade PATH structures. Above-grade and below-grade elements of the PATH terminal could be fully integrated with commercial development to provide benefits to both uses. Truck loading and unloading could be accommodated below grade; thereby reducing the adverse street-level effects of the Church Street location. Furthermore, a terminal building could be located on Church Street to provide greater visibility for PATH. The hall would be oriented to accommodate the predominant pedestrian movements to and from PATH.

Since the "hybrid" option combined many of the advantages of both the Church Street and the WTC "Bathtub" locations, it was determined to be favorable for further study. This option was advanced into preliminary design and is evaluated as the "Preferred Alternative" in this FEIS, as described below.

ALTERNATIVES FOR FURTHER STUDY

NO ACTION ALTERNATIVE

Under the No Action Alternative, a Permanent WTC PATH Terminal would not be constructed, and the temporary station would remain in service to the extent possible. However, as described in Chapter 1, "Purpose and Need," the temporary station was constructed with the principal goal of restoring PATH service to Lower Manhattan as quickly as possible following the terrorist attacks of September 11, 2001. As such, certain components of the station may require replacement or upgrade to extend its service life beyond the anticipated 2009 opening year of a Permanent WTC PATH Terminal.

Under the No Action Alternative, PANYNJ would retain temporary PATH service between New Jersey and Lower Manhattan until either 1) elements of the WTC Memorial and Redevelopment Plan would preclude operations, 2) the station would not safely accommodate passenger demand, or 3) the major elements of the station would exceed their useful service life.

As described in Chapter 5, "Socioeconomic Conditions," the residential and employee population of Lower Manhattan will increase as the redevelopment of the WTC site and other projects are completed. These populations will generate new demand for PATH service as compared to today. As ridership nears the temporary station's design capacity, PANYNJ would need to implement operational adjustments to safely accommodate passengers. Two options

would be considered to extend temporary PATH service beyond its design capacity—reduced service and restricted access.

Reduced train service would result in fewer trains entering and leaving the station during the AM and PM commuter periods. As a result, there would be longer headways between trains, which allow the platforms to be cleared of passengers before the next train arrives. Reduced operations also help the throughput of vertical elements, such as escalators and stairways, by decreasing congestion. As will be described in Chapter 8, Section A, "PATH," reduced operations may result in the diversion of PATH customers to other modes of travel to and from Lower Manhattan.

Restricted access would result in the suspension of entering PATH customers at the temporary WTC station during the AM peak period. A similar operating plan was enacted at PATH's Christopher Street Station in the months following September 11, 2001. Restricted access would prohibit customers wishing to travel from Lower Manhattan to New Jersey in the morning peak period from using the system. Thus, these riders would need to seek alternative modes of travel to reach their destinations. It should be noted that a similar operation could be implemented, albeit in the reverse direction, during the PM peak period.

Restricted access eliminates cross-flow traffic within the station complex and results in more efficient platform operations. Furthermore, vertical elements can operate with a single flow of traffic in a uniform direction. This increases the throughput of these elements and allows for the processing of a larger number of passengers.

Although PANYNJ could implement measures to extend the design capacity of the temporary station, it is anticipated that vital systems within the station would exceed their service life over the next 20 years. Therefore, without a major infusion of capital, it would be necessary to cease operations at the temporary WTC PATH station sometime between 2009 and 2025.

PREFERRED ALTERNATIVE

The Preferred Alternative would result in a new Permanent PATH Terminal on the WTC site. As described above, this alternative was developed through an evaluation of the benefits and constraints of two Terminal locations (WTC "Bathtub" and Church Street) on the WTC site, which was previously described as the "hybrid" location. This alternative combines an above-grade terminal building and sub-level pedestrian concourses on the eastern portion of the site with additional pedestrian concourses, tracks, platforms, and a mezzanine on the western portion of the site. Under this alternative, the Permanent WTC PATH Terminal would have four levels—platform, mezzanine, concourse, and a street-level terminal building.

Proposed Design

Figure 2-2 shows the platform level, which would be located immediately west of NYCT's 1 and 9 train line and atop the concrete slab at the base of the WTC "Bathtub." The platforms and tracks would have a north-south orientation to complete a loop with the Hudson River tunnels. Trains would enter the station from the south Hudson River tunnel (Tunnel F) and would exit via the north tunnel (Tunnel E). With this configuration, PATH trains would enter and leave Manhattan without changing the location of the train's engineer or conductor. Thus, trains could have a short dwell time at the Terminal.

PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure 2-2
Platform Level

The Preferred Alternative would have four platforms (Platforms A through D) and 5 tracks (Tracks 1 through 5). The four platforms would be long enough to accommodate 10-car trains in accordance with PATH's long-range goal to increase the operational capacity of its system.

Platform A would effectively be a lengthening and rehabilitation of the temporary WTC PATH station platform that is adjacent to the east slurry wall. It is constrained to its east by the slurry wall and to its west by Track 1. Due to the narrowness of Platform A, it would not provide sufficient capacity to board and alight trains during peak hours. However, it is being retained as part of the Preferred Alternative to serve five functions: 1) as a failure management egress platform; 2) for access to trains stored on Track 1 during overnight hours; 3) as a service platform; 4) for use to alight trains that would end revenue service at the WTC Terminal; and 5) for staging the movement of trains to Harrison and Journal Square for inspection and repair.

Platform B would effectively be a rehabilitation of the temporary WTC PATH Station platform. It is constrained to the east by Track 2 and to the west by Track 3. It would serve Hoboken-WTC trains on Tracks 2 and 3. Platforms C and D would serve Newark-WTC trains on Tracks 4 and 5. Platform C would effectively be a rehabilitation of the temporary WTC PATH Station platform. It is constrained to the east by Track 4 and to the west by Track 5. PATH would allow both boarding and alighting to Track 4 from Platform C and dedicated boarding to Track 5. Alighting from Track 5 would be to Platform D.

Platform A would range in width from 13 to 23 feet. Platform B would be 30 feet wide, Platform C would be 31 feet, and Platform D would be 30 feet. As described in Chapter 6, "Cultural Resources" the PATH platforms would have architectural treatments to identify the areas at which they overlap with the footprint of the former South Tower. Furthermore, Platform D would contain a glass viewing area atop the portion of the former North Tower that it would cover.

Each of the four platforms would have multiple vertical circulation elements to move passengers between the platform and mezzanine levels. As planned, all platforms would contain elevators in accordance with the Americans with Disabilities Act. Platforms would also contain a combination of stairways and escalators.

The number and location of stairways and escalators is still being planned for Platform A. Platforms B and C would have a total of ten stairways and escalators and Platform D would have a total of 12. Certain structural elements that support the levels above would touch down within Platforms B and C. As planned, these elements would intersect the center of the platform between two stairways, two escalators, or a combination of stairways and escalators. Because these structural elements would not intersect Platform D, two additional stairways and/or escalators would be constructed.

As shown in Figure 2-3, the mezzanine level would have a north-south orientation and would be located directly above the platform level. This level would house fare equipment, vertical circulation to the platforms and concourse level, and up to approximately 5,000 square feet of retail services, such as newsstands and food stalls. The mezzanine level would have two entrances/exits to the above concourse level. An east entrance/exit would direct passengers beneath NYCT's 1 and 9 line to the eastern portion of the WTC site. A west entrance/exit would direct passengers beneath Route 9A toward Battery Park City and the World Financial Center.

Figures 2-4a and 2-4b show the concourse, which consists of a main level and a balcony. The concourse's main level would connect to the mezzanine's east and west entrances/exits via escalators and elevators and would provide connections to offices and retail on the WTC site and

FSTC's Dey Street Underpass, and a corridor beneath Route 9A would allow for access to the World Financial Center. The concourse's balcony level would provide connections to NYCT's Cortlandt Street (1 and 9), Cortlandt Street (R and W), and WTC (E) subway stations.

Figure 2-5 shows the terminal building, which would be constructed on the eastern portion of the WTC site along Church Street near its intersections with Dey and Fulton Streets. It would provide access from Church Street and proposed elements of the WTC Memorial and Redevelopment Plan, including Greenwich Street and a public plaza. The building would also provide for natural light to the concourse level.

Ancillary Facilities

The Terminal would include ancillary facilities and systems, such as mechanical rooms, ventilation, communications, emergency egress, and security. Some of the major elements of this ancillary work are described in the next few paragraphs.

Prior to September 11, 2001, PATH had two ventilation structures within the median of Route 9A. These vent structures were used for both smoke evacuation and piston relief. Piston relief is necessary because when trains operate within a fully enclosed structure, they create air pressure as they move. The structures within the Route 9A median vented this air, thereby reducing the pressure it would otherwise create with the PATH tunnels and Terminal. These vent structures also contained evacuation stairs for emergency egress. The vents were 12 feet tall and were located immediately above the PATH tunnels.

As part of their program to enhance security within and around the WTC site, PANYNJ plans to reconstruct the ventilation structures to be 40 feet tall. Ideally, the future vents would serve the combined purpose of piston relief, smoke evacuation, and emergency egress, as they did prior to September 11, 2001. PANYNJ would construct a north ventilation structure within the Route 9A median above PATH's Tunnel E. The south ventilation structure would also be located within the median of Route 9A above Tunnel F.

NYSDOT is currently evaluating its plans for the reconstruction of Route 9A. Although PANYNJ prefers to locate the PATH vents in the future Route 9A median, it may be necessary to seek other locations (i.e., within the future Memorial Center) if NYSDOT cannot accommodate the vents as port of the ultimate design of the roadway. This FEIS identifies the Route 9A median as the Preferred Alternative for the ventilation structures. If the future plans for the Route 9A Project mandate an alternative location for the vents, FTA and PANYNJ would assess the alternative location through the appropriate NEPA process.

In addition to the emergency egress that would be provided via the vent structures, PANYNJ would construct emergency egress from the Terminal's track/platform and mezzanine levels. Egress stairways would be located near the north and south ends of the Terminal and would provide emergency access to Greenwich Street. The Permanent WTC PATH Terminal would share its emergency egress with the emergency egress for other facilities on the WTC site. PANYNJ plans to collocate one of these stairways within the proposed Performing Arts Center on the site's northwest quadrant and the other on the southwest quadrant within a museum or building that would be part of the WTC Memorial.

PANYNJ would reinforce the roof of the Terminal's east-west pedestrian concourse. The roof of the Terminal's east-west concourse would also serve as the road bed for the future extension of Fulton Street between Route 9A and Greenwich Street. The reinforced roof would consist of hardened, reinforced concrete to enhance the security of the east-west concourse below. The

actual paving, landscaping, and opening of Fulton Street would be undertaken as part of the WTC Memorial and Redevelopment Plan.

The Preferred Alternative includes funds for the reinforcement of the basement walls, which form the "bathtub" within the WTC site. This work is necessary to ensure the structural integrity of the walls and to support future redevelopment of the WTC site, including the Permanent WTC PATH Terminal. As part of the Permanent WTC PATH Terminal's construction, PANYNJ could reinforce the entire west bathtub wall except for portions that would remain visible as part of the WTC Memorial. PANYNJ would also reinforce portions of the east bathtub wall abutting NYCT's 1 and 9 line that were not previously reinforced. If other development on the WTC site does not move forward according to current schedules or plans, it may also be necessary to reinforce portions of the north bathtub wall east of Freedom Tower and portions of the south bathtub wall above the existing PATH substation. It is currently estimated that approximately 30 percent of the required slurry wall repairs would be undertaken as part of the Preferred Alternative.

Construction of the Terminal may also require the demolition and excavation of remaining structures within the eastern portion of the WTC site between NYCT's 1 and 9 line and Church Street, which includes all portions of the former H&M Terminal. This work would also support the future development of the site by others.

The DEIS noted that the removal of portions of the northwest remnant sub-grade structures on the WTC site may be undertaken as part of the Terminal's construction. However, subsequent to the publication of the DEIS, the removal of the northwest remnant sub-grade structures have been undertaken as an independent action pursuant to the stipulations of the Programmatic Agreement prepared for the WTC Memorial and Redevelopment Plan.

Sustainable Design Elements

The Terminal would incorporate the sustainable/"green" design guidelines being developed by the agencies participating in the Lower Manhattan recovery projects. As described below, these measures would include the use of natural lighting, construction materials specifications, energy-efficient design, and renewable energy sources for heating and cooling.

One of the major sustainable/"green" design guidelines developed for the Permanent WTC PATH Terminal is the ability to use a river water system for cooling the Terminal's heating, ventilation, and air conditioning (HVAC) system. River water cooling was also at the WTC site prior to September 11, 2001. The river water cooling system circulates water from the Hudson River through a central refrigeration plant. The river water would withdraw heat from the HVAC system and then would be returned to the River.

The reuse of the existing Hudson River water intakes and outfalls is an economical and energy-efficient method to provide cooling for the components of the Permanent WTC PATH Terminal. The intakes, pumps, outfalls, and associated pipelines that existed prior to September 11, 2001, remain largely intact. Furthermore, since river water, on average, provides lower supply temperature than other alternatives, greater energy efficiency during the heat transfer process would be achieved. Finally, river water cooling reduces the Terminal's demand on the city's infrastructure.

The river water cooling system is being reestablished as part of the overall redevelopment of the WTC site. However, it may not be fully operational before components of the Permanent WTC

PATH Terminal are opened. Therefore, PANYNJ would employ open air-cooling of the Terminal's HVAC systems in the interim.

PANYNJ has filed an application with the New York State Department of Environmental Conservation to renew the State Pollution Discharge Elimination System (SPDES) permit for the WTC's river water cooling system. This application is being reviewed under an independent action. In the event that the permit's renewal is substantially delayed, PANYNJ would maintain the Terminal's temporary cooling system.

Project Cost

The Preferred Alternative for a Permanent WTC PATH Terminal would cost $2.138 billion, which is $186 million more than identified in the DEIS. Since publication of the DEIS, PANYNJ has advanced the design of the Preferred Alternative and has determined that certain components would be more costly than originally estimated. As a result, the Preferred Alternative would have a higher cost than the "Terminal with Liberty Plaza Connection Alternative" presented in the DEIS.

A total of $1.75 billion would be funded by the FTA through the Lower Manhattan Transportation Recovery Effort (see Chapter 1, "Purpose and Need"). The remaining $388 million would be funded by PANYNJ through their capital improvements budget. Table 2-5 shows a breakdown of the project cost by its various components.

Table 2-5
Project Cost

Project Component	Cost (in millions)
PATH Station Elements	$807
East-West Concourse	$208
North-South Concourse	$318
Terminal Hall and Plaza	$805
Total	$2,138

Note: "Other Project Elements" includes costs for security systems and infrastructure; construction staging for temporary PATH service; utility relocation; and other miscellaneous project costs.

Construction of the Terminal is estimated to begin in 2005. Components of the station, including platforms, mezzanine, and certain pedestrian connections, would be completed by the end of 2009. The remaining portions would be completed in 2010.

ALTERNATIVES CONSIDERED AND ELIMINATED

PATH-6 TRAIN CONNECTION

During the scoping process, public interest groups and local elected officials suggested an alternative that would connect the PATH system with NYCT's 6 subway line. Their proposal would extend the PATH tracks through the WTC site to a new station beneath Fulton Street between Greenwich Street and Broadway. Beyond Broadway, a new track would be constructed beneath Park Place to merge with the 6 line, which currently terminates at NYCT's Brooklyn Bridge-City Hall Station.

PANYNJ considered their proposal, including subsequent iterations, and determined that a number of critical construction and operational issues would need to be resolved to make this

alternative feasible. These considerations would likely delay the completion of this Project and may also result in substantial alterations to existing and planned transportation infrastructure.

The general engineering feasibility of this alternative was considered, referring to the NYCT's *MW-1 Track Standards and Reference Manual* (2002). The criteria considered from this manual included a 3 percent maximum grade, minimum 530-foot long stations on a tangent alignment, and the use of spiral transition curves. In order to achieve clearance of existing subway infrastructure in Lower Manhattan, the 3 percent grade would be exceeded within certain portions of the alignment. Furthermore, to achieve a 530-foot station beneath Fulton Street, certain structures may need to be demolished or underpinned. Finally, the alignment of the connection between PATH and NYCT's 6 line may preclude both a temporary and permanent PATH facility on the WTC site. To align tracks between the Hudson River tunnel portals and the proposed Fulton Street station, a complicated curving scheme would be needed, which would forgo NYCT's requirement for spiral transition curves.

The construction of a new station and tracks beneath Fulton Street would require underpinning of existing NYCT subway infrastructure beneath the streets of Lower Manhattan as well as buildings in the vicinity of Fulton Street, Park Row, and Broadway. Underpinning of NYCT's 1 and 9, N and W, A and C, 2 and 3, and 4 and 5 lines would be required. In addition, structural support for station platforms under Greenwich Street, Church Street, Fulton Street, Nassau Street, and Broadway may also be required.

The connection between PATH and NYCT's 6 train would require the reconfiguration of the 4 and 5 line between the Fulton Street and Brooklyn Bridge-City Hall Stations. The proposal would likely require the reconstruction of the Brooklyn Bridge-City Hall Station to allow for increased passenger loads and operational changes on the 6 line. Construction may also require full disruption of 4, 5, and 6 train service to and from Lower Manhattan for an extended period.

NYCT operates the 6 train through a loop formed by an unused station immediately south of the Brooklyn Bridge-City Hall Station. Similar to the arrangement proposed for the Permanent WTC PATH Terminal, this loop operation allows the 6 train to reverse direction without repositioning the train's engineer or conductor. Thus, trains enter and leave their terminal at the Brooklyn Bridge-City Hall Station with relatively short dwell times, which increases the throughput and capacity of the 6 line. The unused station, which provides for this loop arrangement, was part of the original 1904 subway system. Because of its historical and architectural significance, this station is designated a New York City landmark and is considered eligible for listing on the State and National Registers. In order to connect PATH and the 6 line, this station would have to be physically altered, which may adversely affect its historic integrity.

The train cars that operate on PATH and NYCT's 6 line are similar but are not fully compatible. NYCT recently completed procurement of a new fleet of cars for the 6 train. PATH would need to upgrade to these same cars to fully integrate the systems.

NYCT operates 10-car trains on the 6 line, and PATH plans to implement 10-car service on its Newark-WTC line. However, an upgrade to 10-car operations on the Hoboken-WTC line is not planned at this time. Thus, the integration of PATH and NYCT's Lexington Avenue Local line may preclude direct service between Hoboken and Lower Manhattan.

The 6 line operates under the oversight of the Federal Transit Administration (FTA), and must comply with FTA specifications for station and train operations. As described in Chapter 1, "Purpose and Need," PATH operates under the oversight of the Federal Railroad

Administration. In order to integrate these systems, PANYNJ and NYCT would need to consolidate their operating plans under a single federal oversight agency.

Given the above-described constraints of integrating the PATH and NYCT 6 line, this alternative was not considered to be reasonable and was not carried forward for further consideration.

TERMINAL WITH LIBERTY PLAZA CONNECTION ALTERNATIVE

The DEIS considered a Terminal with a Liberty Plaza Connection Alternative. Generally, the Terminal with a Liberty Plaza Connection Alternative would result in the same facility as described above for the Preferred Alternative. However, it would include an additional pedestrian connection under Church Street between the WTC site and Liberty Plaza Park. As such, the lower concourse corridor shown in Figure 2-4a would be extended beyond the WTC site to serve the subgrade tunnel beneath Church Street. Patrons would ascend to street level within the western portion of Liberty Plaza. This alternative would not have altered the design of the platform, mezzanine, and terminal levels, including the connections to subways, buildings on the WTC site, and the FSTC.

The Liberty Plaza connection was estimated to cost $81 million. Thus the total project cost for this alternative would be approximately $81 million more than the estimate presented for the Preferred Alternative.

The analysis presented in the DEIS showed that the Terminal with a Liberty Plaza Connection Alternative would have more intense and/or a greater number of adverse impacts than the Preferred Alternative during construction. As compared to the Preferred Alternative, the Terminal with a Liberty Plaza Connection would result in vibration impacts on a greater number of historic structures, would result in temporary lane closures and pedestrian diversions on Church Street, and would have increased emissions and noise levels. In the long term, the Terminal with a Liberty Plaza Connection would divert pedestrians from street-level to a sub-grade concourse, which could detract from local businesses, and it would reduce the availability of open space within Liberty Plaza Park.

During the public review process for the DEIS, public officials and concerned citizens stated that the Liberty Plaza Connection would adversely impact community character. A public goal for the rebuilding of Lower Manhattan has been to revive its retail and to ensure its longevity as a 24-hour community. Citizens and agency officials believed that the diversion of pedestrians from street-level to the underpass would detract from this goal. Upon further consideration, PANYNJ decided to eliminate the Liberty Plaza Connection as part of the Preferred Alternative.

DESIGN OPTIONS CONSIDERED AND ELIMINATED

The DEIS presented options for the design of certain components of the Permanent WTC PATH Terminal. As planning has advanced, certain components of the project have been finalized such that design options could be dropped from further consideration. The following describes the options previously presented and the outcome of the design process that has occurred since publication of the DEIS.

STAND-ALONE TERMINAL

The construction of the Preferred Alternative would be closely coordinated with the construction of elements of the WTC Memorial and Redevelopment Plan. However, a Stand-Alone Terminal

option was developed to determine the design and cost implications absent elements of the WTC Memorial and Redevelopment Plan. The assumption was that the Permanent WTC PATH Terminal would be constructed without the adjacent commercial and retail facilities on the eastern portion of the WTC site. The only elements of the WTC Memorial and Redevelopment Plan that would advance simultaneously would be the Memorial substructure and Freedom Tower on the western portion of the WTC site. This assumption resulted in three major adjustments to the Preferred Alternative as described below.

- The interface walls with the retail would be replaced with blast resistant glass above street level. Below street level, stand alone walls would be constructed and would be comparable to the walls of an integrated Terminal.
- The terminal building and pedestrian concourses east of the 1 and 9 line would be supported on anchor slab and piles rather than on the foundations of the future WTC office towers.
- Construction and operational costs for mechanicals, electrical systems, and plumbing would be higher with a stand-alone Terminal since these functions could be integrated with the retail and commercial uses of the WTC Memorial and Redevelopment Plan if constructed simultaneously.

It would be feasible to construct a stand-alone Terminal, and its cost would be approximately 5 to 10 percent greater than a facility that is coordinated with other construction on the WTC site. However, the ability to develop retail and commercial facilities subsequent to the Terminal would be much more difficult with potentially large increases in the time and cost required over the coordinated approach.

A Record of Decision was issued for the *WTC Memorial and Redevelopment Plan, Generic Environmental Impact Statement*, in May 2004 and LMDC has been developing plans for the Memorial and uses on the eastern portion of the WTC site. PANYNJ has been working closely with LMDC to coordinate the subgrade infrastructure to ensure that the construction of the Preferred Alternative would not preclude future uses on the WTC site. As such, the Permanent WTC PATH Terminal would be coordinated with elements of the WTC Memorial and Redevelopment Plan. However, given that WTC site development plans may be delayed or may change over time, PANYNJ may advance certain components of the Terminal as integrated and others as stand-alone. The FEIS generally considers the benefits and impacts of an integrated Terminal; however, where Permanent WTC PATH Terminal elements may be stand-alone to advance its design and construction, the potential environmental effects are noted.

ROUTE 9A PEDESTRIAN BRIDGE

NYSDOT is currently undertaking an environmental review for the reconstruction of Route 9A from Barclay to Albany Streets. At present, NYSDOT is considering three alternatives for the roadway: No Action, At-grade, and Short Bypass. Under the No Action Alternative, NYSDOT would rehabilitate the existing "interim" roadway, which was reconstructed following September 11, 2001 to upgrade its pavement and landscaping. The At-grade Alternative would restore the roadway to its eight-lane, pre-September 11, 2001 condition with modifications to accommodate future uses on the WTC site. The third, "Short Bypass," alternative would reroute approximately 75 percent of vehicular traffic through a four-lane, sub-grade bypass. A four-lane, at-grade boulevard would also be constructed to accommodate local traffic and to improve the pedestrian links between the WTC site, the World Financial Center, and Battery Park City.

The design of the Permanent WTC PATH Terminal's connection to the World Financial Center must be coordinated with the outcome of the Route 9A Project. As will be described in Chapter 11, "Infrastructure and Energy," numerous utility lines, including a 66-inch water line, a 78-inch sewer main, a 48-inch water main, and an 84-duct telephone utility, lie beneath the roadbed of Route 9A. If a short bypass is constructed, NYSDOT would relocate these utilities to facilitate their proposed traffic tunnel. This utility relocation would also allow for construction of PATH's sub-grade concourse. In the event that the No Action or At-grade Alternative for the Route 9A Project is selected, NYSDOT may not undertake this utility relocation.

As described in the DEIS, PANYNJ considered a pedestrian bridge over Route 9A as an alternative to the subgrade concourse in the event that utility relocation would not be undertaken by NYSDOT. However, since publication of the DEIS, PANYNJ has determined that the subgrade concourse could be constructed at a lower elevation, which would avoid these utility lines regardless of the selected alternative for the Route 9A Project. As such, the Route 9A pedestrian bridge has been eliminated from further consideration as part of this FEIS.

SOUTH VENTILATION STRUCTURE

The DEIS identified two options for the location of the Terminal's south ventilation structure—Route 9A median and Deutsche Bank.

Under the Route 9A option, the south ventilation structure would be identical to the north ventilation structure described above, but it would be located atop PATH's Tunnel F. Like the north structure, it would serve for piston relief, smoke evacuation, and emergency egress. However, the New York State Department of Transportation raised concerns regarding the location of this building given their planned reconstruction of Route 9A, As such, PANYNJ considered a second option to locate the vent outside the Route 9A right-of-way within the former site of Deutsche Bank.

Under the Deutsche Bank option, PANYNJ would construct the ventilation system within the new office tower planned for the former location of Deutsche Bank. The vent would be at a minimum height of 40-feet above ground and would likely be constructed within a mechanical level of the future building. Because of the proposed building's distance from the PATH tunnels, a vent structure at this location would not be collocated with emergency egress. Therefore, PANYNJ would need to provide for an emergency stairway with access from the planned plaza adjacent to the office tower or within the north or south sidewalk along Liberty Street. As such, this option would result in additional PATH structures and may increase the overall project cost.

Subsequent to the publication of the DEIS, PANYNJ has selected the Route 9A option for the south vent as the Preferred Alternative and will coordinate its design with the selected alternative for the Route 9A Project.

C. ANALYSIS FRAMEWORK

ASSESSMENT OF PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

BASELINE CONDITIONS

The terrorist attacks of September 11, 2001 have resulted in unique conditions under which to evaluate the potential environmental effects of planned projects as prescribed by NEPA. In a typical setting, an EIS considers the effects of a new or expanded project in comparison to a

future condition absent the proposal. The Permanent WTC PATH Terminal, however, would essentially be a replacement of a facility that existed prior to the attacks.

As described in Chapter 5, "Socioeconomic Conditions," the terrorist attacks resulted in the loss of more than 12 million square feet of office space and the relocation of some 80,000 jobs to other parts of the metropolitan area. As a result, today's demand for certain infrastructure and services in Lower Manhattan is much reduced from pre-September 11, 2001 levels. However, other sensitive uses may be more vulnerable to adverse environmental affects following the terrorist attacks than would have been the case prior to September 11, 2001. To fully investigate the potential for future impacts, the technical analyses that follow consider two baseline conditions to formulate future scenarios for the Project Alternatives.

Pre-September 11, 2001 Baseline

The pre-September 11, 2001 baseline condition reflects the built environment in Lower Manhattan prior to the terrorist attacks. The pre-September 11, 2001 baseline is used for the evaluation of potential future long-term environmental impacts and for the preparation of appropriate mitigation measures.

Because the terrorist attacks resulted in drastic differences in the physical and social characteristics of Lower Manhattan, the current environment in Lower Manhattan does not reflect the level of activity that existed prior to September 11, 2001. The planned redevelopment of Lower Manhattan would result in the replacement of much of the real estate and infrastructure that was lost, resulting in increased trips to the area. However, it is anticipated that the environment in the vicinity of the Permanent WTC PATH Terminal could continue to support the level of activity that existed before September 11, 2001. Therefore, the quantified analysis of future impacts and mitigation is based on a theoretical comparison that assumes the terrorist attacks had not occurred, in order to evaluate the future condition when Lower Manhattan has truly recovered and continues to grow.

The pre-September 11, 2001 baseline condition precludes the federally sponsored redevelopment and recovery projects in Lower Manhattan since it is assumed that the terrorist attacks had not occurred. Therefore, the future conditions developed based on the pre-September 11, 2001 baseline does not include the following projects:

- WTC Memorial and Redevelopment Plan;
- Route 9A;
- Fulton Street Transit Center; and
- South Ferry Terminal.

However, other real estate development is assumed to have been constructed whether or not the terrorist attacks had occurred. These projects, therefore, are accounted for in the future conditions based on the pre-September 11, 2001 baseline.

Post-September 11, 2001 Baseline

The post-September 11, 2001 baseline condition reflects the current environment in Lower Manhattan. This scenario considers the loss of the WTC and transportation infrastructure as well as changes in employment and land use resulting from the terrorist attacks.

Because the revitalization of Lower Manhattan would take more than a decade to complete, the post-September 11, 2001 baseline condition is used to project future conditions in the interim (construction period and opening year) analysis years presented in this EIS. It also considers the

numerous projects planned for the redevelopment of Lower Manhattan, including the $4.55 billion transportation recovery projects. In addition to its use in projecting construction and design year conditions, this scenario is applied to the design year conditions without PATH service under the No Action Alternative, since the other recovery efforts would be pursued independently.

ANALYSIS YEARS

To assess the potential impacts of the Project Alternatives, this EIS considers three analysis years—construction period, opening year, and design year. The basic framework for these analysis years is described below.

Construction Period

PANYNJ estimates that construction of the Permanent WTC PATH Terminal would begin in summer 2005, concurrent with other sub-grade work for the redevelopment of the WTC site. The platform and mezzanine levels and portions of the pedestrian connections could be completed in 2006, while remaining portions of the complex would be done in phases between 2007 and 2009. The EIS considers the potential environmental effects throughout the 2005 to 2009 construction period. However, to estimate peak construction period conditions, a critical analysis year of 2006 has been selected. Chapter 3, "Construction Method and Materials," presents the methodology for selecting this critical analysis year.

Opening Year

Construction activity at other sites in Lower Manhattan would continue after the Permanent WTC PATH Terminal is fully operational in early 2009. Due to concerns about cumulative effects and potential changes in pedestrian travel associated with the Project Alternatives, an analysis of the 2009 opening-year conditions is included.

Design Year

Typically, the analysis of impacts associated with a transit facility also anticipates future conditions approximately 20 years hence, also known as the design year. The design year varies from the initial year of operation because it anticipates future development that might increase transit demand and behavioral changes that may result in varied patterns of travel. For consistency with analyses being conducted for other downtown transportation projects and regional forecasts prepared by the New York Metropolitan Transportation Council (NYMTC), this EIS considers a 2025 design year for the Permanent WTC PATH Terminal.

THE FUTURE COMMON TO ALL ALTERNATIVES

A "Future Common to All Alternatives" has been developed for each of the analysis years described above. The Future Common to All Alternatives projects conditions in these various analysis years independent of the Permanent WTC PATH Terminal and provides a base to analyze, assess, and mitigate potential adverse impacts of the No Action, and Preferred Alternatives. The Future Common to All Alternatives considers planned or proposed initiatives that will have direct or substantial indirect effects on development patterns and transportation access to, from, and within Lower Manhattan. The Future Common to All Alternatives also considers known changes in local, state, and federal regulations that may affect this Project's potential to generate impacts as compared to today.

PROJECT ALTERNATIVES

No Action Alternative

As described above, the No Action Alternative would require that PANYNJ continue the use of the temporary WTC PATH station beyond 2009, but because of certain limitations, it is anticipated that the PATH operations between New Jersey and Lower Manhattan would need to be suspended at some point before 2025. To assess the potential impacts of this alternative, this EIS considers that the temporary station would continue operations in 2009 (opening year) but that there would be no PATH service to Lower Manhattan in 2025 (design year).

Preferred Alternative

A detailed analysis of the potential impacts of the Preferred Alternative is presented in all of the technical chapters of this EIS.

ASSESSMENT OF CUMULATIVE EFFECTS

The Preferred Alternative for the WTC PATH Terminal would be part of the larger redevelopment of Lower Manhattan that includes transportation and development projects being sponsored by both public and private groups. Although funded and planned separately, these projects would have a cumulative effect on the character and quality of Lower Manhattan and the region as a whole both during and after construction. Recognizing the potential impacts of such large-scale development in a relatively small geographic area, the FTA developed a framework for the analysis of cumulative effects for their Lower Manhattan recovery projects being reviewed under NEPA.

This framework ensures that findings presented within the individual environmental documents for the federally sponsored projects in Lower Manhattan are based on a consistent baseline condition and analysis approach. Therefore, the analysis of both the potential impacts attributed directly to the Permanent WTC PATH Terminal and those that may result cumulatively are based on guidance developed by the FTA and the sponsors of the Lower Manhattan Recovery Projects. The following describes the framework that was developed and its application to the evaluation of the Permanent WTC PATH Terminal.

FEDERAL GUIDANCE

A Memorandum of Understanding (MOU) was prepared jointly by the Federal Emergency Management Agency, the FTA, the Federal Highway Administration, HUD, the New York State Urban Development Corporation (Empire State Development Corporation) and its subsidiary LMDC, the U.S. Coast Guard, EPA, the U.S. Army Corps of Engineers, the U.S. Fish and Wildlife Service, and the National Marine Fisheries Service in August 2002. This MOU formalized the commitment among the listed Federal agencies to coordinate and accelerate the review of projects under NEPA. The MOU applied to projects developed and/or funded as a result of the September 11, 2001 terrorist attacks. The MOU specified the role of the participating government entities and defined procedures and commitments to ensure a comprehensive yet expeditious environmental review process under NEPA.

To further the federal coordination established by the MOU, the FTA Lower Manhattan Recovery Office published its *Approach to Cumulative Effects Analysis for the Lower Manhattan Recovery Effort* in July 2003. This document provides guidance for the sponsoring agencies being funded from the $4.55-billion Lower Manhattan Transportation Recovery Projects. The principal features of the coordinated analysis are:

- Promoting efficient project delivery and environmental stewardship,
- Advancing each project independently, but in a coordinated manner, and
- Focusing attention on critical environmental factors.

The approach promotes environmental stewardship through the proactive evaluation of environmental factors and includes measures to streamline the review and project delivery. The coordinated approach will ensure consistency between projects through a consistent set of analysis assumptions and methodologies for all of the transportation recovery projects. As a project advances through the NEPA process, its analysis and any identified impacts will be incorporated into the documentation of later projects to ensure a consistent, up-to-date, and comprehensive evaluation of potential cumulative effects.

To expedite the environmental review process, the study of cumulative effects will focus on subject areas that are prone to potential adverse effects. The federal partners and local project sponsors have coordinated to identify five key areas with the highest potential for adverse cumulative effects: access and circulation, air quality, noise and vibration, cultural and historic resources, and economic factors. The local project sponsors coordinated with the FTA and EPA to develop consistent methodologies, assumptions, data sources, and impact criteria for the evaluation of impacts under each of the five cumulative effects subject areas.

The temporary waiver of most transportation air quality conformity requirements provided by Public Law 107-230 allows for these projects to proceed without a full conformity determination. To meet obligations set forth with the conformity waiver, the framework recognizes the need and value of interagency consultation and is consistent with the enhanced interagency consultation procedures set forth during the transportation conformity waiver period.

ENVIRONMENTAL ANALYSIS FRAMEWORK

In response to the federal guidance provided by the FTA, the governmental entities involved with the recovery efforts in Lower Manhattan have developed an environmental analysis framework (see Appendix I). This framework was prepared by LMDC, MTA, NYSDOT, and PANYNJ, in cooperation with the FTA and interested Federal agencies. The framework was used by LMDC, MTA, NYSDOT, and PANYNJ for the preparation of environmental documentation for each of their recovery projects. Local Project Sponsors will be introduced to this framework, as appropriate, when additional federally sponsored recovery projects are identified and prioritized.

The framework considers the regulations set forth by the Council on Environmental Quality (CEQ) and accounts for the guidance of the State Environmental Quality Review Act (SEQRA) regulations, the *New York City Environmental Quality Review (CEQR) Technical Manual*, industry best practices, and public input.

The framework consists of the following components:

- Green Design, Green Construction, and Sustainable Design Principles;
- Construction Environmental Protection Plan;
- Public Involvement and Governmental Entities Coordination Plan; and
- Baseline Assessment of Resources and Coordinated Cumulative Effects Analysis Approach

Green Design, Green Construction, and Sustainability Principles

The Project Sponsors for the Lower Manhattan Recovery Projects have developed a common set of Environmental Performance Commitments (EPCs) that they will each undertake such as design

elements, construction techniques, and operating procedures that will lower the potential for adverse environmental impacts.

Unlike a typical NEPA process, which responds to potential impacts with appropriate mitigation, the EPCs provide specific measures for the avoidance and reduction of potential impacts in advance of the environmental review process (see Appendix I). These EPCs incorporate design features and construction practices to preserve the capacity of the local environment and successfully allow for the development of all of the Lower Manhattan recovery projects. Table 2-6 shows the EPCs that were formalized by LMDC, MTA, NYSDOT, and PANYNJ in September 2003.

Each project sponsor would implement the EPCs through specific actions identified in its public involvement and governmental entities coordination plan, construction environmental protection plan, design documents, and contracts.

The EPCs established a general guidance for developing green design and sustainability principals to reduce the demand for and use of resources during construction and once projects would be operational. Subsequently, PANYNJ has outlined preliminary sustainable design guidelines for the Preferred Alternative, which will continue to be formalized as the Project's design advances.

Principals and actions were organized into six component areas: urban considerations, site, water, energy, materials, and indoor environment. These guidelines are consistent with criteria contained in the NYCT Environmental Guidelines, the U.S. Green Building Council, Leadership in Energy Efficiency (LEED) Guidelines 2.1, and requirements of New York State (NYS) Executive Order 111, "Green And Clean State Buildings And Vehicles," which direct State agencies to be more energy-efficient and environmentally aware, and the NYS Green Building Tax Credit (Chapter 63 of the NYS Laws of 2000), which promotes environmentally sound building practices through a package of tax incentives.

Urban Considerations

For urban considerations, the design guidelines support development in existing urban areas, the development of public transportation by linking inter-modal systems, promote regional mass transit, increase bicycle access, facilitate pedestrian pathways, and improve neighborhood air quality by reducing back-up of traffic into neighborhood streets. To implement these guidelines, PANYNJ would support the existing infrastructure by exceeding a minimum development density, integrate the use of public transportation by providing access to NYCT subway and buses, and provide the services and support to facilitate pedestrian movements.

Site

PANYNJ would integrate water, material, and energy resources to optimize the utilization of all resources on site. The project would implement a storm water management plan to collect storm water from site surfaces and implement a filtration structure in conjunction with the Water Management Plan. Pollution prevention would also be in place to control site erosion. PANYNJ would integrate existing slurry walls, bathtub excavation, elements of the temporary PATH station, and utilities for re-use in the new site development. PANYNJ would also study opportunities for "waste to reuse" for food, paper, metal, and construction waste. To reduce the effect of the urban heat islands phenomena, PANYNJ would provide green infrastructure, along with albedo surfaces to mitigate thermal loading of site surfaces and building roofs. Light pollution would be minimized by reducing sky glow, glare, and light trespass.

Table 2-6
Environmental Performance Commitments

Technical Area	Proposed Commitments
Air Quality	Use ultra low sulfur diesel fuel in off-road construction equipment with engine horsepower (HP) rating of 60 HP and above.
	Where practicable, use diesel engine retrofit technology in off-road equipment to further reduce emissions. Such technology may include Diesel Oxidation Catalyst or Diesel Particulate Filters, engine upgrades, engine replacements, or combinations of these strategies.
	Limit unnecessary idling times on diesel powered engines to 3 minutes
	Locate diesel powered exhausts away from fresh air intakes.
	Control dust related to construction site through a Soil Erosion Sediment Control Plan that includes, among other things: a) Spraying of a suppressing agent on dust pile (non-hazardous, biodegradable); b) Containment of fugitive dust; c) Adjustment for meteorological conditions as appropriate.
Noise and Vibration	Where practicable, schedule individual project construction activities to avoid or minimize adverse impacts.
	Coordinate construction activities with projects under construction in adjacent and nearby locations to avoid or minimize impacts.
	Consider condition of surrounding buildings, structures, infrastructures, and utilities where appropriate.
	Prepare contingency measures in the event established limits are exceeded.
Cultural and Historic Resources	Establish coordination among projects to avoid or minimize interruption in access to cultural and historic sites.
	Initiate public information and involvement outreach with sensitivity to local cultural resources.
	Identify public information outlets that will receive and provide current information about access during construction.
	Consult with the New York State Office of Parks, Recreation, and Historic Preservation and the New York City Landmarks Preservation Commission regarding potentially impacted, culturally significant sites. Monitor noise and vibration during construction at such sites, as appropriate.
Access and Circulation	Establish a project-specific pedestrian and vehicular maintenance and protection plan.
	Promote public awareness through mechanisms such as: a) signage; b) telephone hotline; and c) Web site updates.
	Ensure sufficient alternate street, building, and station access during construction period.
	Regular communication with New York City Department of Transportation and participation in its coordinated construction efforts.
Economic Effects	Coordinate with LMDC, Downtown Alliance or other entities to minimize residential and retail impacts as required through: a) relocation assistance, as applicable, to persons to businesses physically displaced by the project; and b) focus on essential business and amenities to remain in Lower Manhattan.
	Add appropriate signage for affected businesses and amenities.
Design for the Environment	Energy Efficiency/Renewable Energy
	Enhanced Indoor Environmental Quality
	Conserving Material and Resources
	Environmentally-friendly Operations & Maintenance
	Water Conservation and Site Management
	Waste Management and Recycling (including during construction)

Water

PANYNJ would incorporate sustainable water principals by providing on-site collection of storm water and treatment of waste water. Where practicable, the project would use reclaimed water for toilet flushing, cooling tower makeup, and landscape irrigation. PANYNJ's measures to improve water use to reduce the burden on municipal water supply include efficient water fixtures, automatic controls, and waterless urinals.

Energy

Energy conservation is another component to sustainable development that PANYNJ would implement. Optimizing of energy use would consist of premium efficiency motors, superior insulations, and sensors on light fixtures. Another "green" principal PANYNJ would incorporate is to utilize site-generated and/or purchased renewable energy for a portion of total energy use. PANYNJ would reduce emission of ozone-depleting chemicals by specifying that building systems have zero levels of chlorofluorocarbon refrigerants and use only insulation materials that do not contain chlorine-based gases. PANYNJ would also institute an independent authority to execute a commissioning plan, which would comprise design phase reviews, contractor submittal reviews, functional testing, training, operations and maintenance reviews.

Materials

A key component to sustainable development is material management in construction. The "green" design principals for material management include a comprehensive materials management plan, construction waste management, material reuse, recycled content of the material, proximity of manufactured material to project site, wood certification, and agricultural materials. PANYNJ would develop a comprehensive materials management plan to optimize the use of materials and to reduce waste generation to landfill. This plan would reduce the travel distance for building products and systems. PANYNJ would coordinate with other uses on the site to maximize recycling and to provide a centralized recycling facility.

Indoor Environment

Indoor environmental quality would be enhanced with the following sustainability principals: indoor air quality performances and monitoring, daylight and outdoor views, reduction of contaminants from materials, chemicals and particulates, acoustics, and thermal comfort. PANYNJ would implement an Indoor Air Quality Management Plan that includes architectural and HVAC design strategies to establish high indoor air quality and provide a plan for a permanent monitoring system with centralized controls to supply feedback on ventilation performance and the resultant concentrations of carbon monoxide, carbon dioxide, and volatile organic compounds (VOCs) in accordance with the NYS Executive Order 111, Article 19.638.7(d)(1). PANYNJ would also implement a Materials Management Plan to minimize use of materials with high levels of VOCs and other toxic characteristics. PANYNJ would implement a facility for system default to 100 percent outside air, where practicable, and in balance with energy conservation. PANYNJ would incorporate natural lighting into the terminal building and concourses to reduce demand for artificial illumination. An ambient lighting system would be coordinated with day lighting strategy for flexible illumination.

PANYNJ would provide a plan to reduce potential noise and vibration from mechanical equipment in conformance with the recommendations of the American Society of Heating, Refrigerating, and Air-Conditioning Engineers Applications Chapter 46 Design Guidelines. PANYNJ would provide a plan to manage air flow, moisture, and thermal energy and use an integrated system to monitor and control air temperature in each zone.

Construction Environmental Protection Plan

As the design and environmental review of the Permanent WTC PATH Terminal is advanced, the PANYNJ will provide a detailed outline of the EPCs and any other procedures to be implemented to protect sensitive resources that may be affected by the project's construction. This plan will describe how the initial condition of the resources will be assessed, how the

construction work will be implemented to avoid or minimize impacts, and how the project will be monitored during construction. The plan will use the best available information from the ongoing construction coordination process for projects in Lower Manhattan and a shared projects inventory being developed by LMDC. The plan will also provide for an effective means of disseminating current information to the public and other developers.

Public Involvement and Governmental Entities Coordination Plan

As per the framework, PANYNJ will maintain on going communication with the community at-large (including environmental groups, interested governmental entities, and the general public) and they will be involved as the Project is advanced through the design and construction process.

PANYNJ has developed a public involvement plan that has and will continue to guide the outreach for the Permanent WTC PATH Terminal EIS (see Chapter 18, "Agency Coordination, Process, and Public Participation"). A key goal of this plan is to communicate potential impacts during construction and to coordinate with other projects in the vicinity to avoid, or at least minimize, adverse effects on the environment. As the process continues, this plan will be updated to identify a protocol for 1) addressing comments received during the construction phase; 2) communicating appropriate current information to the public, including implementation schedules; and 3) means and measures of on-going coordination with other projects. The process will build on an existing construction coordination protocol among parties already involved in rebuilding Lower Manhattan.

Baseline Assessment and Coordinated Cumulative Effects Analysis Approach

The framework establishes the components of the baseline assessment and coordinated cumulative effects analysis to be used for the Federal Transportation Recovery Projects. These parameters have been applied not only to the study of cumulative effects but also to the analysis of potential impacts resulting directly from the construction and operation of the Permanent WTC PATH Terminal. The guidelines specifically addressed in the framework are as follows:

- Each Project Sponsor will address cumulative effects, as applicable, as part of its independent project-specific environmental review process.
- The baseline to be used for the No Build comparison required under NEPA will be pre-September 11, 2001 conditions.
- The baseline used for assessment of construction-related impacts for each project will be adjusted, where appropriate, to reflect anticipated conditions at the time of construction.
- Project Sponsors will share appropriate information, databases, and documentation of the baseline and forecasted conditions.
- Each Project Sponsor will apply a consistent approach for the evaluation of cumulative effects focused on the five following resources: Air Quality (including the Enhanced Procedures during the Transportation Conformity Waiver Period); Pedestrian and Vehicular Access and Circulation; Historic and Cultural Resources; Noise and Vibration; and Business/Economic Interests
- The geographic area for analysis will be the area of Lower Manhattan south of Canal Street but, where appropriate, the geographic area may be adjusted for specific resources.

- Each Project Sponsor will adhere, at a minimum, to the set of common EPCs to lower the potential for adverse environmental impacts, thereby lessening the potential for each project to contribute to overall adverse cumulative effects.
- As each project matures through the NEPA process, the findings of the project will be incorporated into the cumulative effects analysis for the projects that follow it. As such, the project on which findings have been issued will constitute an existing condition for the cumulative effects analysis of the next project.

The "Methodology" sections of Chapters 4 through 14 of this FEIS detail the specific data sources, study areas, and criteria applied to the assessment of potential impacts associated with the Preferred Alternative. The approach to the evaluation of cumulative effects is further described in Chapter 15, "Cumulative Effects."

Since publication of the DEIS, PANYNJ has coordinated with NYSDOT and MTA to refine the EPCs and other mitigation commitments identified in the environmental documents for the Lower Manhattan Recovery Projects. As such, PANYNJ and MTA have agreed to additional measures to minimize or mitigate air quality emissions, noise, and vibration during the construction of their projects. These measures are described in more detail in Chapter 9, "Air Quality" and Chapter 10, "Noise and Vibration."

Furthermore, on November 22, 2004, New York State Governor George E. Pataki signed an Executive Order creating the Lower Manhattan Construction Command Center (see Appendix I). The Command Center will administer the construction of project's within Lower Manhattan that either 1) have a construction value of more than $25 million; 2) require governmental actions or permits or; 3) require work within a City or State street or highway.

The Command Center will coordinate community information, construction logistics, utility coordination, environmental compliance and safety, and diversity and equal opportunities in employment. The Command Center will be managed by an Executive Director to be appointed by the Governor and the Mayor of the City of New York. The Mayor will also appoint a Director of City Operations to act as a liaison between the Command Center and City officials. An Executive Committee, to be chaired by the Executive Director, will be appointed to facilitate communications between the Command Center, the Lower Manhattan Project Sponsors, and other key city and state departments and agencies. Chapter 3, "Construction Methods and Materials" provides a more detailed description of the roles and functions of the Lower Manhattan Construction Command Center.

As described in Chapter 18, "Process, Agency Coordination, and Public Participation," the Lower Manhattan Construction Command Center is only one of the several forums in which PANYNJ will coordinate with other agencies and the general public as the planning and construction of the Permanent WTC PATH Terminal moves forward. As the owners of the WTC site, PANYNJ will maintain close contact with LMDC, MTA, and NYSDOT as their efforts move forward. In addition, PANYNJ will continue to coordinate with the project's Section 106 consulting parties on issues relating to archaeological and historic resources, and they will continue their outreach with project stakeholders and community groups to report on the project's progress. ✳

Chapter 3: Construction Materials and Methods

A. INTRODUCTION

This chapter describes the activities required for construction of the Preferred Alternative for a Permanent World Trade Center (WTC) PATH Terminal. The potential environmental impacts that may result from construction and any required mitigation measures are detailed in Chapters 4 through 14 of this Environmental Impact Statement (EIS).

The purpose of this chapter is to develop a framework for the analysis of potential impacts from the construction of the Preferred Alternative. At this time, design of the project is still ongoing, and will continue to evolve. Similarly, planning for construction of the project will also evolve. Therefore, while the actual construction process may differ somewhat from the scenario discussed below, the analysis methods have been conservatively developed to maximize the potential for construction-related impacts. Specifically, it has been assumed for concurrent construction activities that the peaks will overlap and cumulatively affect air quality, noise, and traffic conditions to a higher degree than what is likely to occur. Therefore, any measures required to mitigate these impacts would then be sufficient for any number of possible future construction scenarios.

B. NO ACTION ALTERNATIVE

Under the No Action Alternative, it is assumed that construction activities associated with the WTC Memorial and Redevelopment Plan, the Fulton Street Transit Center, South Ferry Terminal, the Route 9A Project, and certain private developments would occur on or near the WTC site as described in Chapter 15, "Cumulative Effects." As such, certain modifications may be required to maintain temporary WTC PATH service and to ensure the safety of PATH riders as construction occurs around and above the station complex. Furthermore, it is assumed that specific plans to maintain and protect temporary PATH service and any required modifications to the station in support of other area developments would be undertaken by the respective project sponsors.

As described in Chapter 2, "Project Alternatives", minor construction may be required within and adjacent to the temporary station to extend its service life through the opening year, but such activities would be similar to station maintenance that occurs on a regular basis throughout the PATH system. Generally, the effects of this maintenance are anticipated to be far less than those with the construction of a Permanent WTC PATH Terminal since the activities described below for the Preferred Alternative would be far more intense.

C. PREFERRED ALTERNATIVE

The DEIS presented a construction schedule and phasing plan developed in October 2003. This plan was prepared as part of the coordinated efforts for the cumulative effects analysis

framework for the Lower Manhattan recovery projects. The phasing plan presented in the DEIS consisted of 6 Elements as follows:

- Element 1: Permanent Tracks, Platform Conversion, Mezzanine, and Concourse Construction;
- Element 2: Tunnels under 1 and 9 Line;
- Element 3: Route 9A Connection;
- Element 4: Liberty Plaza Connection;
- Element 5: Excavation/Deconstruction of the temporary PATH station; and
- Element 6: PATH Terminal Building.

As noted in Chapter 2, "Project Alternatives," the Liberty Plaza Connection is not being proposed as part of the Preferred Alternative. Therefore, Element 4 of the phasing plan described in the DEIS has been eliminated in this FEIS. Furthermore, since publication of the DEIS, project engineering and design have progressed allowing for a more refined assessment of the construction schedule and phasing. The analysis in the DEIS assumed construction would begin in the first quarter of 2005, but it is now anticipated to start in the third quarter of 2005. Furthermore, the DEIS analysis of construction impacts assumed a more fast-tracked approach with the majority of construction activities occurring in 2006. Based on current engineering data, design considerations, and coordination issues with other separate undertakings on the WTC site, the construction activities would be more evenly distributed through 2006, 2007, and 2008. Since the analysis in the DEIS was based on a higher level of activity than is currently proposed, the corresponding construction-related impacts are higher than what is now expected. Assumptions in the DEIS regarding construction scheduling and phasing have not been revised for the FEIS, as they represent the maximum predicted noise levels and pollutant concentrations that could possibly occur under the most aggressive construction schedule. Mitigation measures developed with respect to these maximum predicted levels would be even more effective under a less aggressive construction schedule.

This section presents the construction schedule and phasing for the Preferred Alternative as currently proposed. Section D, "Construction Analysis Framework" describes the construction scenario that was originally developed for the DEIS and is used in this FEIS to assess potential impacts and to recommend mitigation.

SCHEDULE

Construction of the Preferred Alternative is comprised of five major elements, within which there are stages to be performed concurrently or sequentially. As shown in Figure 3-1, these five construction elements would occur from approximately July 2005 through early 2010. However, the major components of the Terminal are expected to be operational in 2009.

During all elements of the project, construction workers and supervisors would arrive on site either in personal vehicles or via mass transit. A limited amount of parking would be available on-site and would primarily be used by supervisors arriving in light trucks. Other workers arriving by private vehicle would park off-site. Heavy and light trucks would be present during demolition and construction stages throughout all elements; however, the number and type of trucks would vary between elements.

Generally, the hours of construction would be Monday through Saturday from 7 AM to 6 PM in one 10-hour shift. A 10-hour work shift was assumed not only for the construction of the Preferred Alternative but was also assumed for analyses prepared for the World Trade Center

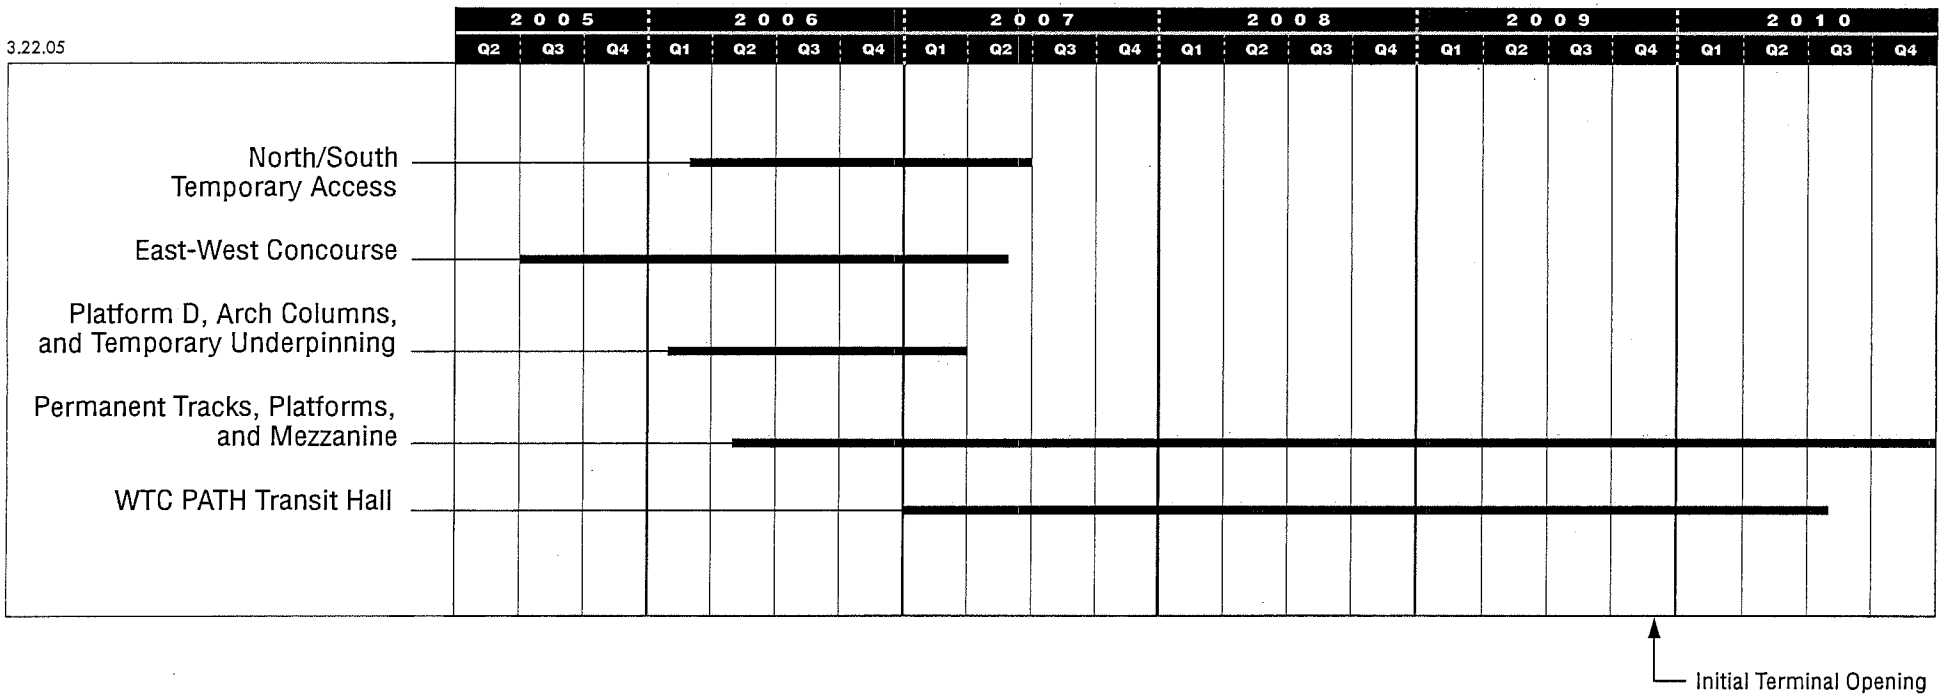

Figure 3-1
Construction Schedule

Memorial and Redevelopment Plan. The proposed hours of construction are consistent with New York City construction guidelines.

In some cases, it may be necessary to conduct construction activities at night, particularly when temporary lane closures would be needed or to coordinate and stage activities for the daytime shift. These nighttime activities would be limited throughout the construction period and would have fewer staff than the daytime shift. These nighttime activities would be required to meet the New York City Noise Control Code (NYC Administrative Code Title 24 §201 et seq.), which does not allow for activities that would exceed specific noise criteria.

CONSTRUCTION ELEMENTS

For descriptive purposes, the construction process for the Preferred Alternative is divided into five elements. Prior to or during construction of the Preferred Alternative, the bathtub walls surrounding the western portion of the WTC site will require permanent reinforcement and stabilization to protect the Preferred Alternative from extensive infiltration of water from the Hudson River and potential flooding. All or part of this bathtub reinforcement and stabilization work may be done as part of the Permanent WTC PATH Terminal project. Following is a brief description of each of these project components.

NORTH/SOUTH TEMPORARY ACCESS

Beginning in late 2005, PANYNJ would construct temporary access to the temporary WTC PATH station. As currently planned, the temporary access would be located on Vesey or Liberty Street or both and would allow for the continued use of the temporary station as construction of the Permanent Terminal proceeds. The temporary access would be maintained until the Terminal Hall and other permanent street-level entrances can be provided. The duration for the construction of this element is 15 months.

EAST-WEST CONCOURSE

During this phase, PANYNJ would construct the east-west pedestrian connection through the WTC site. This phase also includes the construction of the east-west connection beneath Route 9A and of the headhouse adjacent to the World Financial Center. The portion of the connection beneath Route 9A may be constructed by NYSDOT using cut-and-cover methods or by PANYNJ with mining. If NYSDOT pursues a short-bypass alternative for the Route 9A Project, then they would construct the east-west concourse in tandem with their construction of the roadway tunnels. If NYSDOT pursues an at-grade alternative for Route 9A, then the east-west concourse would be constructed at nearly the same elevation by PANYNJ; however, the tunnel would be mined with spoils removed from within the WTC site or from a shaft near the World Financial Center that would eventually provide the vertical connection between the concourse and the street-level headhouse. The full duration for the east-west concourse construction is 36 months.

The hardening of the roof of the east-west concourse, which would eventually become the road bed of Fulton Street between Route 9A and Greenwich Street would occur during this element. The hardening of roof would involve the laying and reinforcement of high density concrete. Upon completion, the hardened road bed would serve as staging for the construction of Freedom Tower, which is being undertaken independent of the Preferred Alternative for the Permanent WTC PATH Terminal. The road bed would be prepared for street traffic as part of a separate undertaking.

PLATFORM D, ARCH COLUMNS, AND TEMPORARY UNDERPINNING

This element of construction involves the preparation work needed to maintain PATH operations as components of the Permanent Terminal are construction. It includes the laying of a temporary Track 6 and the permanent Platform D within the WTC "bathtub." The temporary track is needed to allow for continuous PATH operations as other tracks are reconfigured for use in the Permanent Terminal. Platform D provides access to trains using Track 6 and is, therefore, the first permanent platform to be constructed. Track 6 would be removed once PATH service can be fully restored on Tracks 1 through 5. During this phase of construction, the column supports for the Terminal's arches would be placed. Also, temporary underpinning of the 1 and 9 Line would be undertaken to support the later widening of the passageway between the mezzanine level and the concourse level. The total duration of this element is 20 months.

PERMANENT PLATFORMS, TRACKS, AND MEZZANINE

This component of construction includes the major structural and finishing work for the platform and mezzanine levels of the Permanent Terminal. It includes placement of the structural arches, mezzanine construction, the underpinning of the 1 and 9 Line and construction of the passageway between the mezzanine and concourse levels, the lengthening and upgrade of Platforms A, B, and C, the completion of Platform D, and the construction of PATH's ventilation structures in the median of Route 9A. The total duration for this phase of construction is 45 months.

Grouting beneath the existing NYCT 1 and 9 subway tunnel would be performed from within this tunnel to protect the existing subway tunnel from the subsequent excavation work. Grouting is used in soft soil to stabilize surrounding soils as a tunnel is excavated. In this case, a machine would be used to stabilize the surrounding soils by injecting cement or a similar material to form a hard tunnel shell. It would involve the use of compressed air operated drill rigs and grout pumps.

Excavation and tunneling beneath the subway would occur from the west bathtub and proceed east. Tunneling would be accomplished via conventional mining techniques (e.g., shield with hand or mechanical excavation) and would require removal of existing piling supporting the subway tunnel and replacement with new piles/foundations. Spoils would be removed via the existing ramp to Liberty Street or by lifting to the surface with a crane and skip box.

Demolition of temporary and construction of the permanent tracks, platforms, and mezzanine would occur alternating between northern and southern portions of track, platform, and mezzanines. To maintain train service and passenger safety and access, only one half (either the northern or southern half) of the platform would be demolished and converted, then the second half would follow. This stage of activity would continue until all tracks and platforms are converted. All work would occur within the west bathtub of the WTC site with access from the existing ramp from Liberty Street. No street closings are anticipated for this work to take place.

Two ventilation structures with emergency egress would be constructed as part of the Preferred Alternative. The north ventilation structure would be below and within the median of Route 9A near the projection of PATH Tunnel E. Similarly, the south ventilation structure would be within Route 9A above Tunnel F. This construction would also involve the installation of fans. Estimated duration for construction of the ventilation shafts is approximately 6 months. The vent structure construction would be undertaken in coordination with NYSDOT.

WTC PATH TRANSIT HALL

This element consists of construction of the PATH terminal building, which includes the construction of all sub-grade and above-grade levels, the north-south pedestrian concourse, and the Terminal's mechanical and support systems. A preliminary estimate for the duration for the construction of the building area is 42 months, from late 2006 through early 2010. Lane closings on Church Street may be required for materials delivery and for the erection of pre-fabricated trusses and for the structural steel framing.

MATERIALS DELIVERY AND SPOILS REMOVAL

The vehicles, primarily trucks, needed to deliver materials for construction activities and remove demolition debris would be required to adhere to established site ingress and egress truck routes. For access to the site, trucks arriving and departing would use Route 9A, Broadway, Liberty Street, Church Street, and Barclay Street (see Figure 3-2).

The staging of materials would generally occur within the WTC site or along Vesey and Liberty Streets, which would remain closed to vehicle access during the construction period. At limited times during the Project's construction, it may be necessary to stage materials on Church Street, which would require temporary lane closures. PANYNJ and its contractors would coordinate such activities with the New York City Department of Transportation.

Excavation and demolition of existing site infrastructure and remaining soil would result in the removal of spoils throughout the construction period. As described in Chapter 12, "Contaminated Materials," these spoils would be removed from the site by licensed handlers and would be tested prior to disposal in accordance with U.S. Environmental Protection Agency, New York State Department of Environmental Conservation, and New York City Department of Environmental Protections guidelines and policies. Spoils would be deposited in a licensed facility.

ENVIRONMENTAL PERFORMANCE COMMITMENTS

As discussed in Chapter 2, "Project Alternatives," PANYNJ has committed to a series of common Environmental Performance Commitments (EPCs) as part of the Environmental Analysis Framework for Federal Transportation Recovery Projects in Lower Manhattan. Actual requirements and specifications implementing the commitments will be set forth in PANYNJ's design and contract document.

As described in the DEIS, the project sponsors developed a framework for construction coordination, which included several working groups to address issues that have been identified in the individual environmental documents for the Lower Manhattan recovery projects and to implement the EPCs. The sponsors established a Schedule Working Group, a Logistics Working Group, a Traffic Working Group, and a Standards Working Group. Through this coordinated approach to the construction of individual projects, the project sponsors strove to meet or exceed the EPCs and to investigate and remediate issues and concerns that could arise during the construction process.

Since the publication of the DEIS, Governor Pataki established, by way of an Executive Order, the Lower Manhattan Construction Command Center (see Appendix I). This entity will coordinate the construction of the Lower Manhattan Recovery Projects but will also coordinate any other construction projects in Lower Manhattan with a value in excess of $25 million through 2010. The Command Center will have an Executive Committee consisting of representatives from the various project sponsors and other key state and local agencies. The

Command Center and its Executive Committee will be managed by an Executive Director, who was appointed in February 2005.

As stated in the Executive Order, the functions of the Command Center will be:

- "Coordinating the work of the participants in the rebuilding process and ensuring that the construction in Lower Manhattan proceeds as scheduled by mediating conflicts in schedules and street and site access between construction projects, agencies, and the Lower Manhattan Community;"
- "Coordinating protocols, contract requirements and activities outside of individual project limits through planning on a daily basis throughout construction for government agencies, developers, construction managers, general contractors, and contractors;"
- "Coordinating construction projects to minimize inconvenience for residents, workers, pedestrians, vehicles, and commuters;"
- "Ensuring that the Lower Manhattan area remains neat, clean and orderly throughout construction;"
- "Communicating with residents, businesses, and the general public through a communications director working with each agency's communications and public outreach personnel; providing a central focus on issues critical to the local community and the construction industry, by coordinating initiatives, public outreach, and information;" and
- "Utilizing technology to facilitate coordination of projects."

Although the Command Center and the Lower Manhattan Project Sponsors may further refine the EPCs as construction moves forward, PANYNJ has already committed to specific measures to mitigate potential impacts resulting from the project's construction. As noted in Chapter 2, "Project Alternatives," the EPCs address five categories as follows:

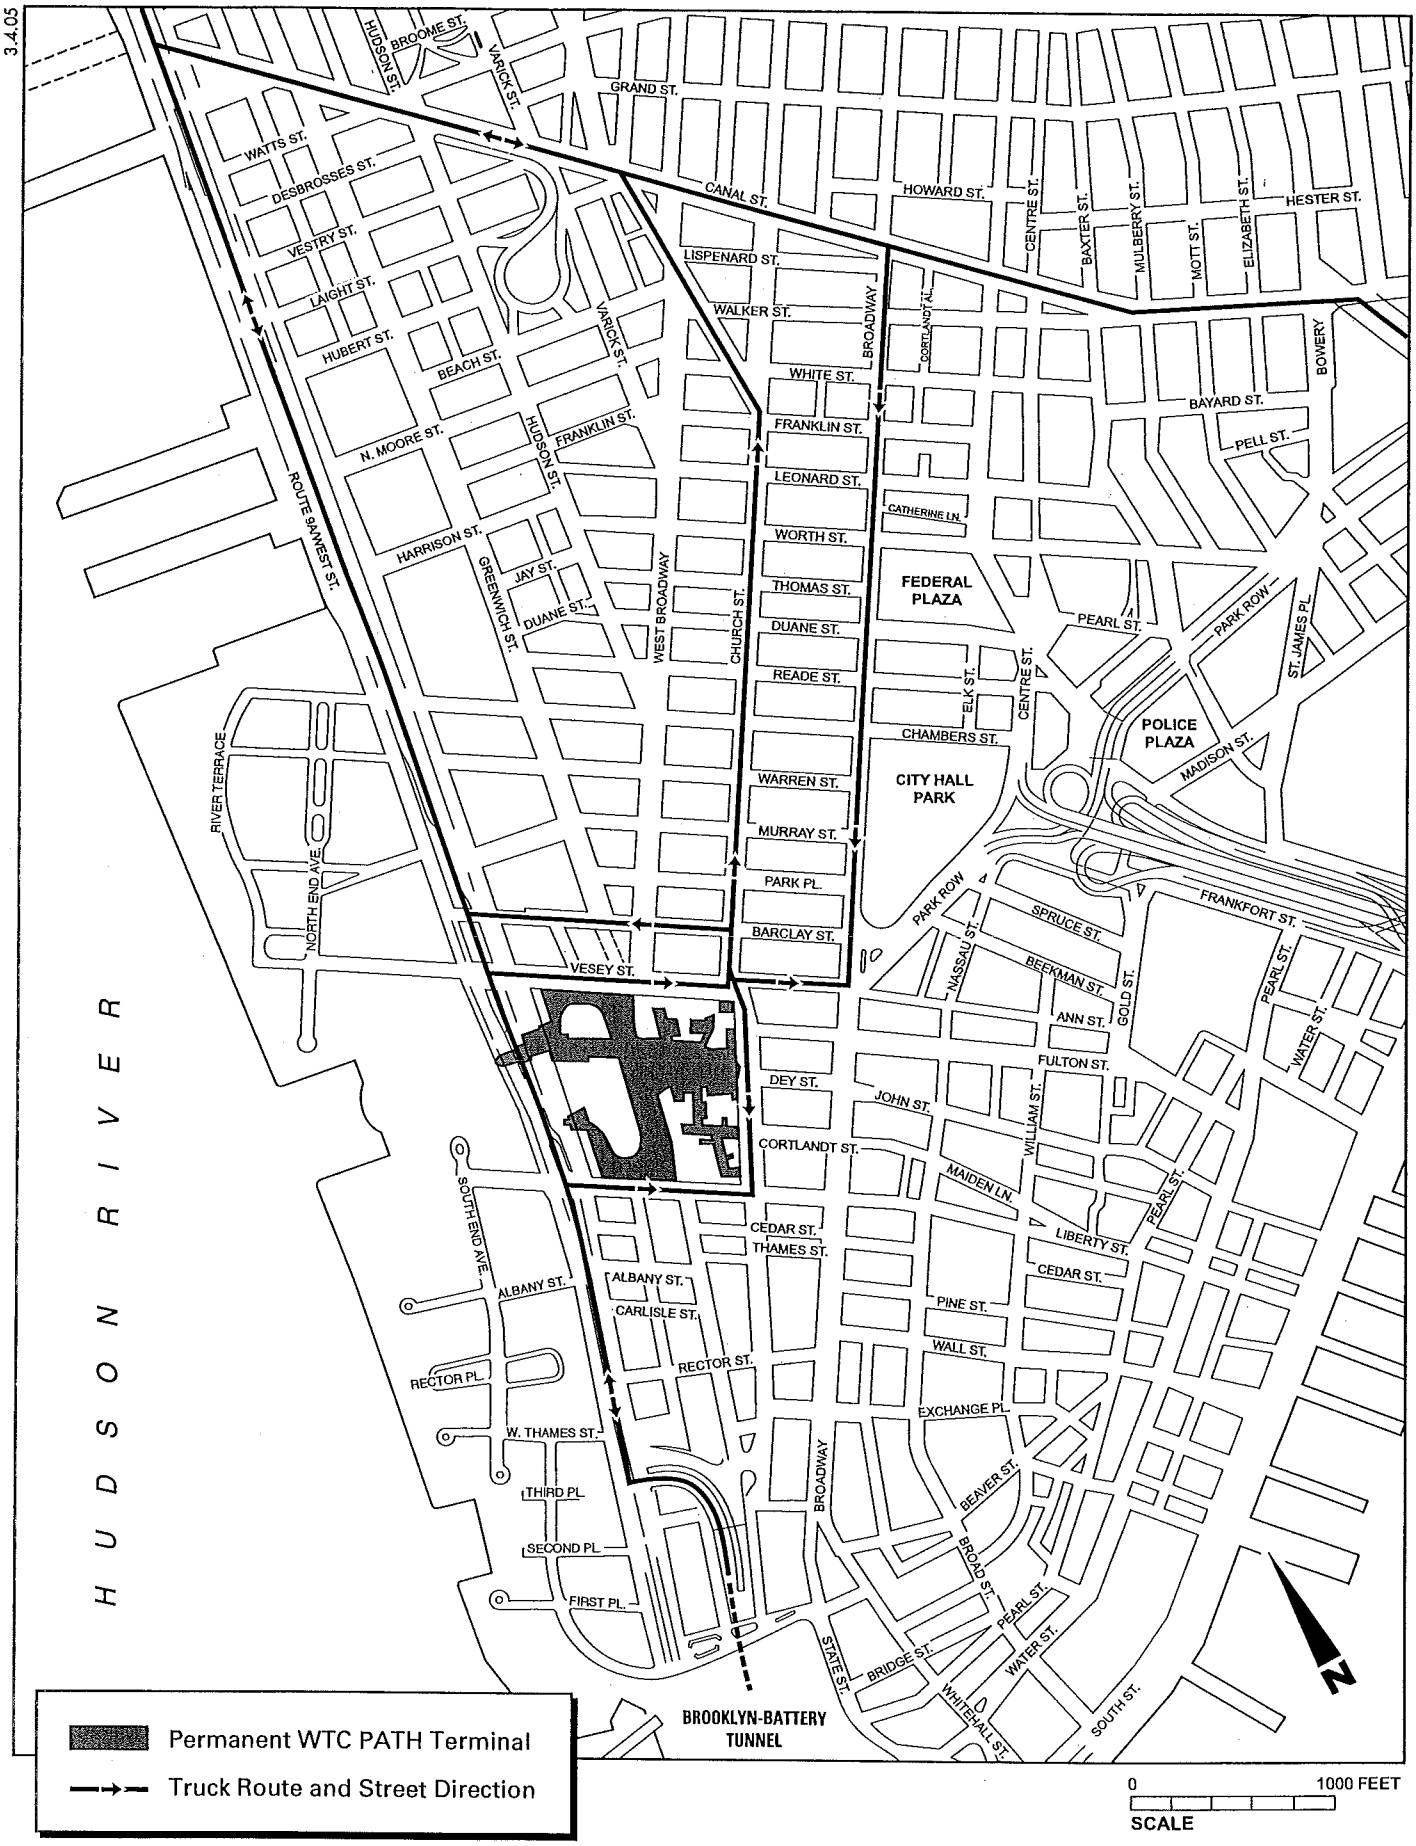
- Economic Conditions;
- Cultural Resources;
- Access and Circulation;
- Air Quality; and
- Noise and Vibration.

Chapter 5, "Socioeconomic Conditions," Chapter 6, "Cultural Resources," Chapter 8, Section B, "Vehicular Traffic and Parking," Chapter 9, "Air Quality," and Chapter 10, "Noise and Vibration," describe these commitments, plans for their implementation, and their anticipated benefits to local conditions during the construction period.

PANYNJ will also ensure that its EPCs are met independent of the Lower Manhattan Construction Command Center. Coordination and circulation plans will accompany the Project's design documents, and the project's contract documents and construction specifications will include the EPC requirements for contractors and specific measures to monitor these commitments as construction moves forward.

D. CONSTRUCTION ANALYSIS FRAMEWORK

As described above, the DEIS presented a construction analysis framework developed through a coordinated effort with the sponsors of the Lower Manhattan recovery projects in October 2003.



PERMANENT WTC PATH TERMINAL
Draft Environmental Impact Statement

Figure 3-2
Truck Routes

This framework considered the peak period of activity (2006) when four elements of the Terminal would be in simultaneous construction. The Liberty Plaza Connection was one of the four elements assessed for the peak construction year in the DEIS. Since the Preferred Alternative does not include the Liberty Plaza Connection, this element is dropped from the construction analysis framework for this FEIS. Furthermore, although the current phasing and schedule of the Preferred Alternative varies somewhat, the analysis framework presented in the DEIS reflects a more aggressive schedule and is considered a reasonable yet conservative framework to evaluate potential impacts and mitigation.

The assessment of potential impacts due to project construction requires the development of a framework that reasonably simulates, both temporally and spatially, those activities that may adversely affect the adjacent environment. To develop this framework, a critical analysis year is first selected. For construction projects that extend over multiple years, a critical year is identified to isolate the greatest potential for adverse effects. In the case of the Preferred Alternative, the peak period of construction activity would occur in 2006. Generally, the assessment of impacts in the critical or peak construction year results in an analysis and mitigation that would also alleviate adverse effects in other years of the construction period since activities on and near the Preferred Alternative would be less intense than in the critical analysis year. For each stage of construction, a peak condition is developed that replicates the daily activities that may be encountered for each stage. These activities include the type and location of construction occurring, a roster of construction equipment on site, the hours of operation for each equipment type, and a quantification of the numbers of trucks providing material or demolition transport. It is also necessary to develop estimates of construction worker vehicle trips even though these are not expected to occur in the peak analysis hours but may be substantial over a 24-hour period. Once these activities are detailed over the individual construction stages, an analysis scenario can be developed that is used as input to the traffic, air quality, and noise impact assessments.

CRITICAL ANALYSIS YEAR (2006)

For the Preferred Alternative, 2006 has been selected as the critical analysis year. During most of that year major work on three elements (Elements 1 through 3) would be occurring simultaneously. While work on Element 5 would be beginning at the end of 2006, construction activities on Elements 1 and 2 would be nearly complete. Therefore, the peak activities associated with Element 5 would not overlap with those of the first three elements. A detailed description of the work for Elements 1 through 3 follows.

Some construction activities may occur sequentially and some may occur simultaneously to increase efficiency and progress. The movement of heavy and light trucks would be a daily recurring activity throughout the duration of each stage of each element (i.e.., trucks to and from the site). On the other hand, some construction activities specific to each element (i.e., spoils removal, concrete pouring, and underpinning) would occur in stages and would not overlap, as it may be necessary to complete one activity before proceeding to the next. Additionally, one process or section of an element (e.g., reinforced steel installation) may be finishing while another is beginning in another area of the same work zone (e.g., pouring concrete). The analysis takes this into consideration by developing a reasonable number of concurrent activities for the impact assessment.

The average daily truck traffic numbers represent each vehicle counted once. It is assumed that the vehicles (i.e., numbers shown) would make one trip in and one trip out of the site (i.e.,

round-trip). Truck trips have been assumed to be evenly distributed throughout the day because the major truck generators, like demolition and concrete pouring, would require staging throughout the day at a more or less even pace as work proceeds.

As stated above, the work week would be six days, and a work day would be one 10-hour shift between the hours of 7 AM and 6 PM. However, the construction equipment is assumed to be operating a maximum of nine hours per day. Additionally, the total number of employees arriving at the site includes those arriving in personal vehicles as well as employees traveling via mass transit to the site. Although some activity may occur outside the assumed 10-hour shift during certain times of the construction period, these activities would employ far fewer workers and implements of equipment than the daytime shift. Thus, the daytime, 10-hour shift is considered a conservative scenario for the evaluation of potential construction-period impacts.

It is assumed that each material delivery truck (e.g., concrete, steel) would idle for approximately one-half hour per day (i.e., 5 percent of the 10-hour day).

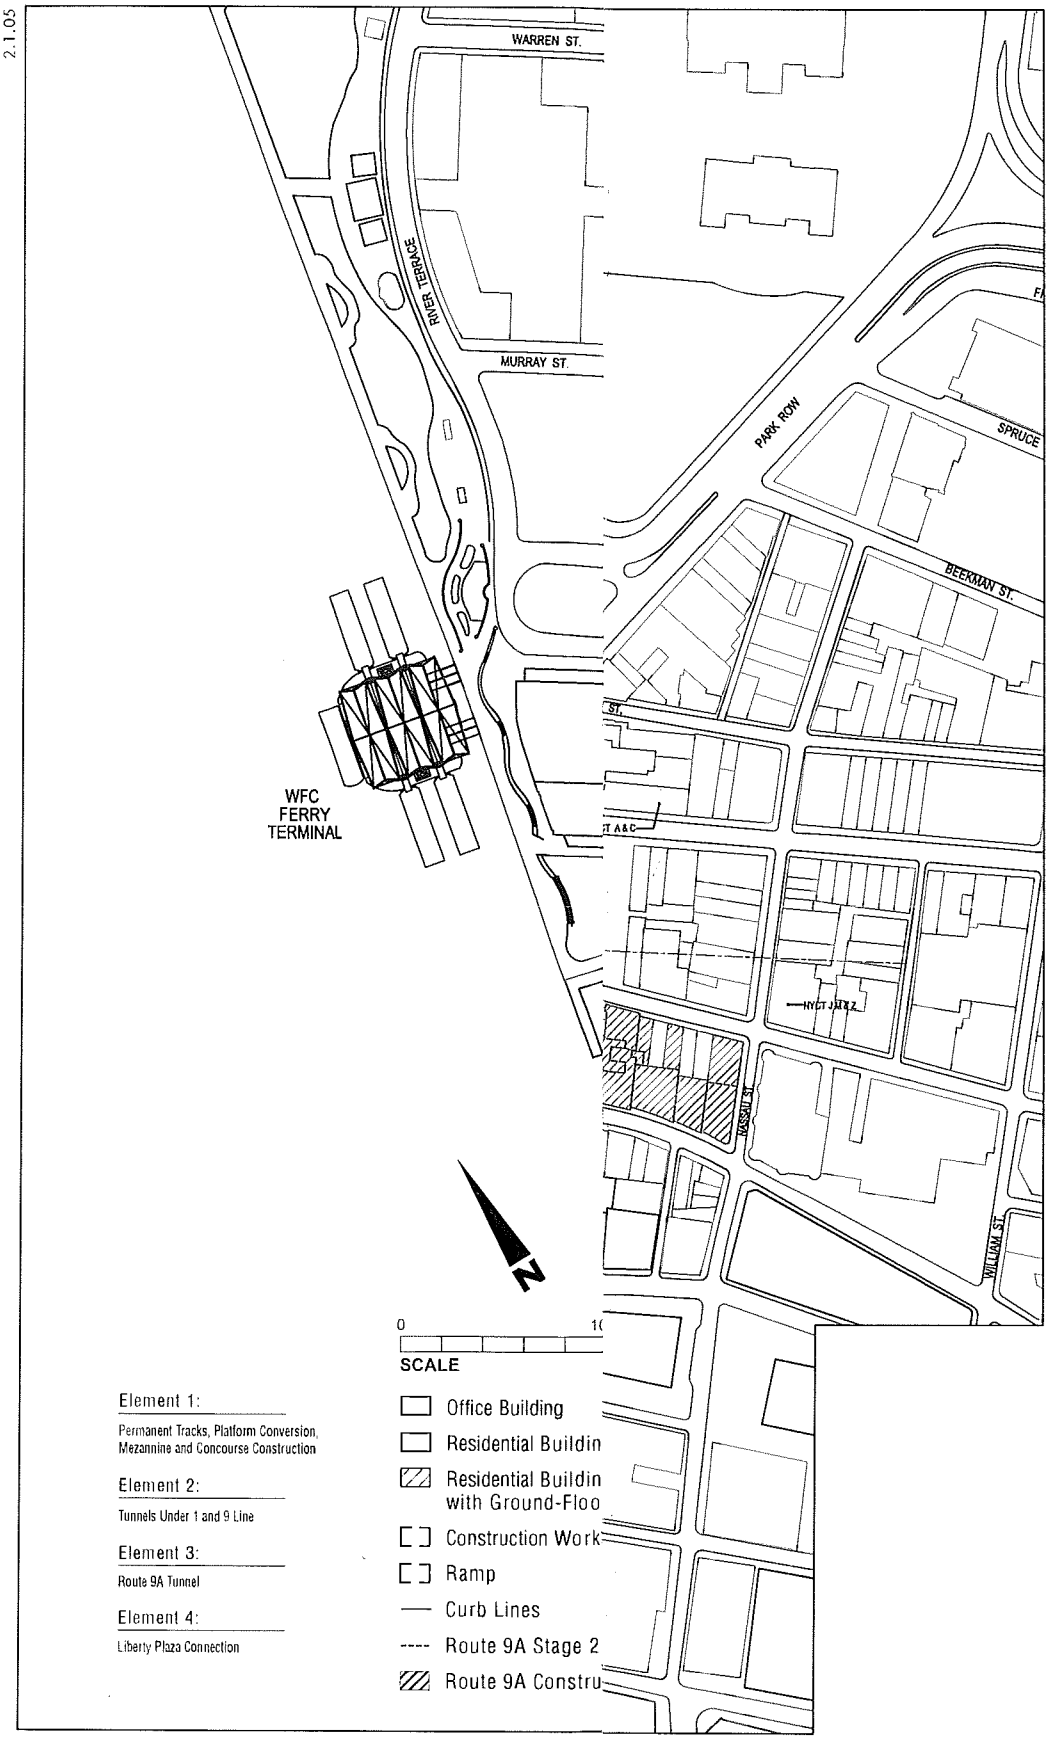
DESCRIPTION OF CONSTRUCTION ELEMENTS

The following section describes in greater detail the construction activities in Elements 1 through 3. Figure 3-3 shows the areas in which the elements would take place and generally where the construction equipment would operate on site.

Element 1 – Permanent Tracks, Platform Conversion, Mezzanine and Concourse Construction

Element 1 would take place in the central portion of the site (see Figure 3-3). This element consists of constructing a temporary track to add to the existing five tracks, then demolishing temporary platforms and mezzanines and installing structural steel and reinforcing steel/concrete for new platforms and mezzanines. Demolition activities would take place for one-half month (i.e., 10 days) to prepare half a platform section for construction. The construction of the new platforms/mezzanines would involve the installation of reinforcing steel, concrete, and structural steel. The time required to complete one-half of a platform would be approximately three months. While each activity (e.g., placement of reinforcing steel) may only take a total of 30 working days, it may be spread out over the entire three-month cycle. Including demolition, the entire stage would last approximately 3.5 months. There would be two periods, each 3.5 months in duration, per stage and three stages for a total of six periods and 21 months.

While the exact pattern of construction is not known at this time, it has been assumed for the environmental analysis that all construction activities could be occurring simultaneously. Table 3-1 presents the number of trucks for each stage of this element. The table shows both the number of daily trucks required for an activity and the assumed number for the environmental impact assessment (i.e., the peak trips). As shown, it has been conservatively assumed that both demolition and construction are occurring on the same day. Only the trucks related to mobilization are not included in the peak trips, since it is not possible for mobilization to occur concurrently with the other activities. The maximum number of concurrent daily truck trips during demolition in Element 1 is estimated at 16 trips while construction would require an estimated 71 trucks. As shown in the table, the majority of the heavy-duty trucks coming to the site are related to the demolition and concrete pouring. Since demolition activities only occur for 10 days over the 3.5-month cycle, a total of 87 trucks (light- and heavy-duty) could only be reached on a small number of days, if at all.



PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure 3-3
Elements 1-3

2.1.05

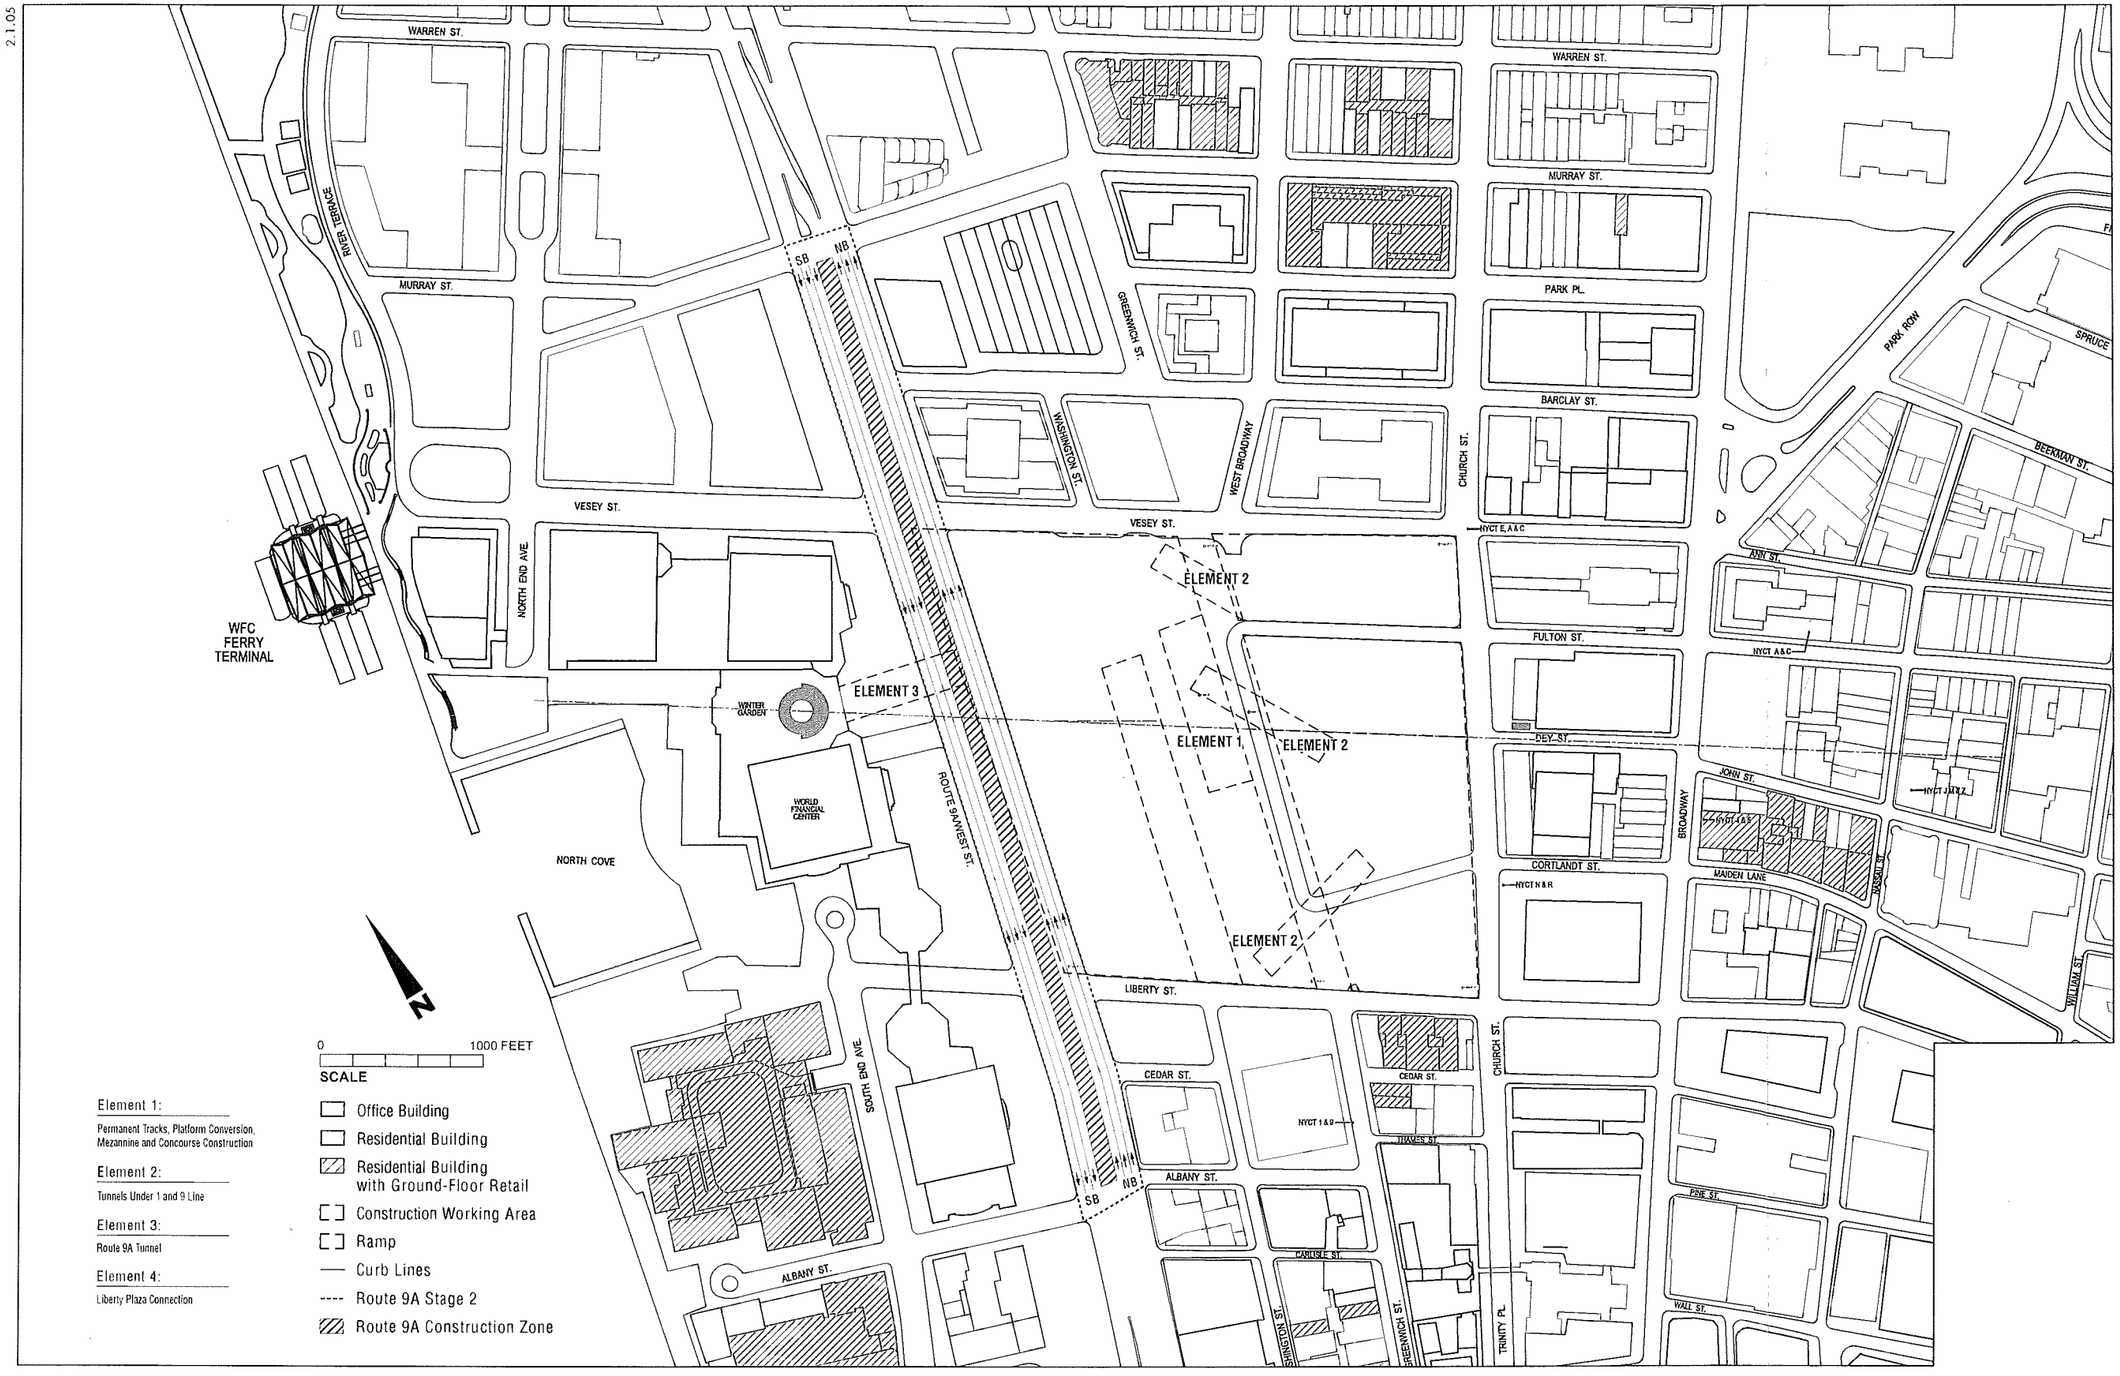


Figure 3-3
Elements 1-3

Table 3-1
Element 1 – Summary of Off-Site Construction Activity

Activity	Peak Daily Trucks	Average Daily Trucks
Demolition		
Debris Removal*	5/day	3/day
Service Trucks	3/day	2/day
Light Trucks	8/day	6/day
Construction		
Concrete*	50/day	2/day
Reinforcing Steel*	1/day	1/day
Structural Steel*	4/day	1/day
Service Trucks	3/day	2/day
Light Trucks	13/day	11/day
Total	87/day	28/day

Note:
* Heavy trucks would be used for these activities.

The equipment usage for the demolition and construction activities has also been conservatively estimated. Table 3-2 presents a roster of equipment that would be used for the demolition and construction activities. These tables also show the number and types of equipment in use for peak days and the number of days in a year that each piece would be operating. It is important to distinguish between the peak days and the annual usage since some air pollutants, notably particulates and nitrogen dioxide, have an average annual standard that will be assessed in the impact analysis. The peak days will be used for the short-term (i.e., 8- and 24-hour averages) air quality and noise assessments, while the annual numbers will be used for the long-term standards (30-day and annual average). The maximum number of days that a piece of equipment would be used in a year is 288, which represents a six-day work week. A 48-week work year has been assumed to account for holidays and inclement weather conditions.

All of the equipment needed for the demolition, placement of reinforcing steel, pouring of concrete and erection of structural steel is included in these tables. As shown, a wide range of equipment would be employed for the various construction elements. Some equipment types (e.g., crane) are used in most activities while others are specific to an individual activity (e.g., concrete pump).

Element 2 – Tunnels under 1 and 9 Line

Element 2 consists of tunneling and underpinning of the 1 and 9 subway line at three locations, each labeled in Figure 3-3. Activities in this element include underpinning of the subway tunnel (six months), excavation and removal of spoil material (six months), and placement of steel and concrete within the excavated tunnel (eight months). The total duration of this element is 20 months. Underpinning would occur slightly ahead of excavation and spoil removal followed by the placement of concrete and steel to complete the activity. Since all three types of work occurring in this element could be performed in multiple locations, and given that this work could be performed together, all three activities could occur simultaneously during a typical work day.

Table 3-2
Element 1 – Summary of On-Site Construction Activity

Equipment	Quantity
Air Compressor for Impact Wrenches	2
Air Compressor for Pavement Breakers	1
Concrete Pump	1
Crawler Crane	1
Hi-Lift (forklift)	2
Hydraulic All-terrain Crane	1
Hydraulic Excavator with Hoe Ram	1
Hydraulic Excavator with Thumb	1
Impact Wrenches	20
Pavement Breakers	4
Welding Machines	2
Workers in Private Vehicles during Demolition	6/day
Workers in Private Vehicles during Construction	11/day

Table 3-3 presents the number of trucks needed for each stage of Element 2. The maximum number of peak daily truck trips during construction is estimated at 16.

Table 3-3
Element 2 – Summary of Off-Site Construction Activity

Activity	Peak Daily Trucks	Average Daily Trucks
Spoil Removal*	6/day	2/day
Underpinning*	1/day	1/day
Concrete/Steel*	2/day	1/day
Service Trucks*	2/day	1/day
Light Trucks	5/day	3/day
Total	16/day	8/day

Note:
* Heavy trucks would be used for these activities.

As previously discussed, the grouting operations for the underpinning would occur from within the subway tunnel. This activity would occur during late-night or weekend periods to minimize the effects to subway operations. The grouting is used to control the flow of soil and/or groundwater during the subsequent excavation stages. Concurrent with grouting, the internal framing for the subway structure would be reconstructed and socketed into bedrock with caissons. Temporary sheet piling would also be installed before excavation begins.

The staging for the tunneling work and placement of the concrete/steel structural elements would occur in the west bathtub. Tunneling would proceed east in a step-wise fashion. After grouting, underpinning and dewatering are completed for a section, the tunneling would proceed and material would be excavated and removed. As the tunneling progresses, the structural elements (i.e., concrete and steel) would be installed in the previously excavated tunnel space. Once the tunneling is complete, finishes would be installed.

Table 3-4 shows the types and quantity of equipment that would be used for this element.

Table 3-4
Element 2 – Summary of
On-Site Construction Activity

Equipment	Quantity
Air Operated Grout Drills	2
Concrete Pump	3
Crawler Crane	1
Hi-Lift (forklift)	2
Backhoe or Boom Cutter for Tunneling	2
Welding Machines	1
Workers in Personal Vehicles	6/day

Element 3 – Route 9A Connection

Element 3 would take place in the northwestern portion of the site (see Figure 3-3). This element consists of tunneling under Route 9A for the pedestrian concourse under this roadway. Under the short-bypass alternative for Route 9A, excavation would employ cut and cover construction methods beneath the existing roadway.

As described previously, the methods employed to construct the Route 9A connection depend upon the alternative selected for the Route 9A Project. Under the short-bypass alternative, NYSDOT would construct PATH's connection on behalf of PANYNJ. NYSDOT would use cut-and-cover methods and would incorporate the excavation of PATH's connection with their construction efforts for the roadway tunnels. If the at-grade alternative is selected for Route 9A, then PANYNJ would construct the concourse beneath Route 9A by mining.

The cut-and-cover method of construction would result in the maximum predicted impacts on traffic circulation and noise as compared to mining; thus, these chapters consider the cut-and-cover method for the evaluation of impacts. The potential impacts on air quality vary depending upon the construction method; therefore, the analysis presented in Chapter 9, "Air Quality," considers both methods of construction.

Furthermore, the short-bypass alternative for the Route 9A Project requires relocation of utilities in the vicinity of the roadway; however, these utilities would not be relocated if the at-grade alternative is pursued. Although utility relocation is not required in the proposed location of PATH's Route 9A connection, it is described below as part of the coordinated cut-and-cover method.

It is anticipated that the structure would be completed in two halves. If the Route 9A short bypass is selected as the alternative in this location, the cut-and-cover excavation would be integrated for the two projects. Basically, the ceiling of the concourse would become the floor of the short bypass.

Due to the amount of existing deep utilities, piles, timber cribbing and other obstructions in the eastern portion of the planned concourse area, a slurry wall would be used to create the temporary excavation. For the remaining portions of the concourse the excavations would be created with interlocking piles that can be grouted to form a watertight seal.

The construction of the concourse under Route 9A would be staged to minimize the disruption to the World Financial Center and the existing roadway. Shallow utilities would be temporarily

relocated and/or protected in-place until construction is complete in that area. Once the utilities have been relocated, the excavation work would begin. As the work progresses, the walls of the excavation (i.e., either slurry or interlocking piles) would be laterally supported by internal bracing. The concourse would be constructed as a separate box within the temporary excavation. Each portion of the concourse would have to be bulk-headed until the next portion is constructed and the two can be connected. Once completed, the excavation would be backfilled and work on the other half (e.g., eastern or western depending upon sequencing) of the roadway could begin.

Table 3-5 presents the number of trucks for each stage of Element 3. As shown, the peak daily trucks would be 15 since it is assumed that all operations could occur simultaneously. Table 3-6 summarizes the types and quantities of equipment that would be used during this phase of construction.

Table 3-5
Element 3 – Summary of Off-Site Construction Activity

Activity	Peak Daily Trucks	Average Daily Trucks
Spoil Removal*	5/day	2/day
Underpinning*	1/day	1/day
Concrete/Steel*	2/day	1/day
Service Trucks*	2/day	1/day
Light Trucks	5/day	4/day
Total	15/day	9/day

Note:
* Heavy trucks would be used for these activities.

Over the 15-month duration for this element, each activity (underpinning, excavating and placement of concrete/steel) would occur for approximately one-third of the time. Therefore, while the assumptions for the peak day include all equipment operating simultaneously, the annual usage reflects that equipment such as the welding machines or concrete pump would be in use for only one-third of the year.

Table 3-6
Element 3 – Summary of On-Site Construction Activity

Equipment	Quantity
Air Operated Grout Drills	3
Concrete Pump	1
Crawler Crane	1
Hi-Lift (forklift)	2
Pavement Breakers	1
Backhoe	1
Welding Machines	2
Workers in Private Vehicles	6/day

Summary

A summary of the peak trucking activity (i.e., total number of light and heavy trucks that would be on site during construction) in Elements 1 through 3 is presented in Table 3-7. As discussed above, since activities in all elements could potentially overlap, it is conservatively assumed that a total of 118 trucks could arrive on site per day during project construction. Since each truck would travel both to and from the project site, this would represent 236 daily truck trips.

Table 3-7
Summary of Total Peak Daily Trucks (Elements 1 through 3)

Table 3-5	Light Trucks (Per Day)	Heavy Trucks (Per Day)	Total Trucks (Per Day)
Element 1	21	66	87
Element 2	5	11	16
Element 3	5	10	15
Total for All Elements	31	87	118

Of these 118 trucks, 87 would be heavy-duty trucks while 31 would consist of light-duty or subcontractor pick-up trucks. In addition to the delivery and service vehicles generated by the Preferred Alternative's construction, it is estimated that a small number of construction workers would arrive at and depart the area by car. The subsequent traffic, air quality and noise assessment reflect the different characteristics of each of these vehicles. ✱

Chapter 4: Land Use, Neighborhood Character, and Public Policy

A. INTRODUCTION

This chapter examines the effects of the Preferred Alternative within the context of existing and future land use and development trends, neighborhood character, and public policy. The analysis assesses the Preferred Alternative's ability to support the economic recovery of Lower Manhattan as the third largest central business district in the United States. This chapter describes the anticipated changes in land use, neighborhood character, and public policy that are independent of the Preferred Alternative in each of the analysis years and assesses its potential impacts.

B. METHODOLOGY

Three analysis years—2006 (construction year and critical analysis year), 2009 (opening year), and 2025 (design year)—are considered. While the analysis is primarily based upon conditions that exist today at the Project Site and in the surrounding study area (defined below), a discussion of the environment prior to the events of September 11, 2001 is included in this chapter to provide an overall context for the analysis which follows. Anticipated changes in land use, neighborhood character, and public policy that are expected to occur independently of the Preferred Alternative by each analysis year are identified, and its potential impacts to land use, neighborhood character, and public policy are assessed.

Projections of potential future baseline conditions were developed based on the New York Metropolitan Transportation Council's regional modeling for its Regional Transportation Plan. However, these projects were adjusted to local levels based on current knowledge of existing and proposed Lower Manhattan land use. As described in Chapter 2, "Project Alternatives" and Chapter 15, "Cumulative Effects," PANYNJ has coordinated with the other sponsors of the Lower Manhattan Recovery Efforts (Lower Manhattan Development Corporation, Metropolitan Transportation Authority, and New York State Department of Transportation) to develop a consistent approach to the evaluation of potential environmental effects for their respective projects. The methodology for this land use and neighborhood character analysis follows this guidance, and the development of baseline and future conditions has been closely coordinated between the project sponsors.

STUDY AREA AND SUBAREAS

The Preferred Alternative would be constructed almost entirely within the bounds of the approximately 16-acre WTC site, bounded by Vesey Street to the north, Church Street to the east, Liberty Street to the south, and Route 9A to the west (see Figure 4-1). Street level access points and below-grade connections would extend farther, from the World Financial Center (WFC) on the west side of Route 9A in Battery Park City (BPC) to Liberty Park Plaza located east of Church Street between Liberty and Cedar Streets. These areas are referred to collectively as the Project Site.

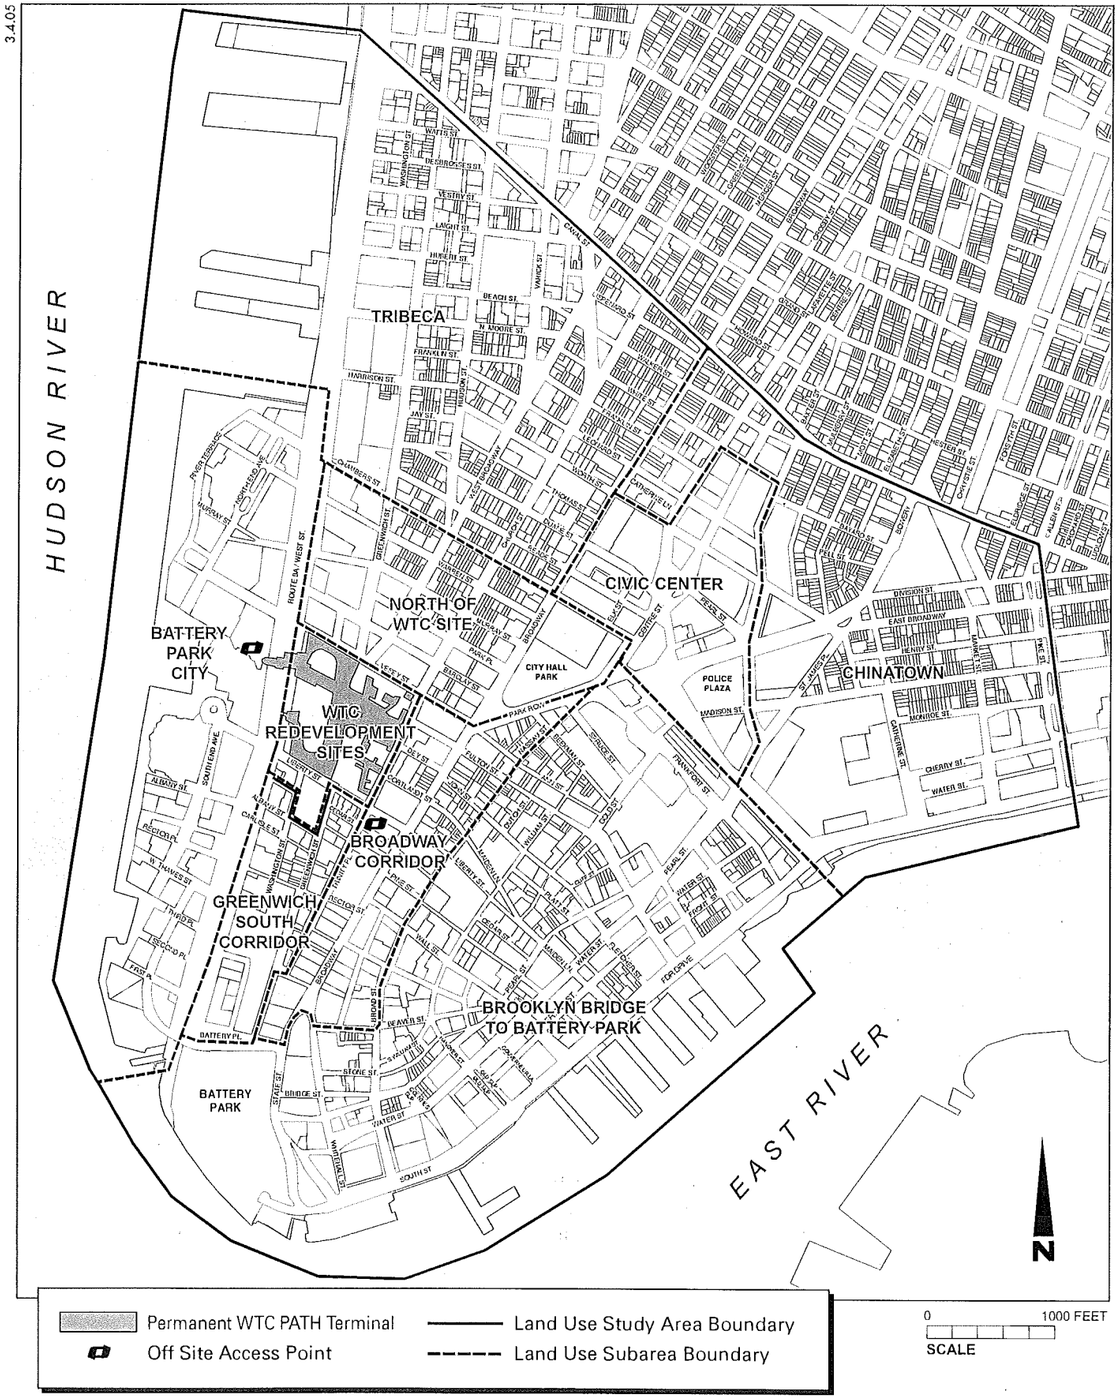
For the purposes of assessing existing and future land use, public policy, and neighborhood character, the land use study area surrounding the Project Site has been divided into nine subareas established based on geographic boundaries as well as commonly accepted neighborhood boundaries.

While the Project Site, as defined below, is largely contained within the boundaries of the former WTC site, the areas to be used specifically to construct the Preferred Alternative are analyzed separately from the rest of the developments expected to occur at the WTC Redevelopment Sites, as defined below. The Project Site and the five subareas immediately surrounding the Project Site represent the primary catchment area for PATH riders and the areas where impacts from the Preferred Alternative are most likely to occur. They are also the areas that experienced the greatest impacts from September 11, 2001 and its aftermath. The remaining four subareas are located further away from the Project Site and therefore are less likely to be affected by the Preferred Alternative. However, these areas capture almost all additional PATH riders who travel to Lower Manhattan, and are included to be consistent with the study areas established for other major projects in the area, including the Lower Manhattan Development Corporation's (LMDC) WTC Memorial and Redevelopment Plan.

To assess potential off-site impacts, a Lower Manhattan study area was defined which includes all uses south of Canal Street. For discussion purposes, this study area is divided into nine subareas as shown in Figure 4-1 and described below.

- *WTC Redevelopment Sites:* (1) the WTC site, bounded by Vesey, Church, and Liberty Streets, and Route 9A; and (2) the two city blocks south of the WTC site, one bounded by Liberty, Greenwich, Albany, and Washington Streets, and the other bounded by Liberty, Washington, and Cedar Streets and Route 9A, plus portions of Liberty and Washington Streets.
- *North of WTC site*, bounded by Chambers Street to the north, Vesey Street to the south, Route 9A to the west, and the eastern boundary of City Hall Park to the east.
- *Broadway Corridor*, extending from Vesey Street and Pace Plaza in the north to Beaver Street between Trinity Place/Church Street and Nassau/Broad Streets in the south.
- *Greenwich South Corridor*, bounded generally by Liberty Street to the north, Trinity Place to the east, Battery Place to the south, and Route 9A to the west.
- *Battery Park City*, encompassing the area between Route 9A and the Hudson River, from approximately Chambers Street to Battery Place.
- *Tribeca*, bounded by Chambers Street to the north, Broadway to the east, Canal Street to the south, and the Hudson River to the west.
- *Chinatown below Canal Street*, bounded by Canal Street to the north, Pike Street and the East River to the east, the Brooklyn Bridge to the south, and Pearl Street to the west, in addition to the blocks between Broadway and Pearl Street from Canal Street in the north to Worth Street/Clavin Place in the south.
- *Civic Center*, bounded by Pearl Street to the east, the Brooklyn Bridge to the south, and Broadway to the west, and extending north to Worth Street/Clavin Place between Lafayette and Pearl Streets.

3.4.05



PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure 4-1
Land Use Study Area

- *Brooklyn Bridge to Battery Park*, bounded by the bridge to the north, Centre/Nassau/Broad Streets to the west, the East River to the east, and south of Beaver Street/Battery Place in the southwest corner.

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

PRE-SEPTEMBER 11, 2001 BASELINE CONDITIONS

Prior to the September 11, 2001 attacks on the WTC, the Project Site was occupied by the WTC PATH Terminal located in the WTC complex. As the Preferred Alternative would effectively result in the Terminal's replacement, an understanding of the conditions that existed on the Project Site and in the surrounding area when the original Terminal was active will help to provide the context for the analysis which follows. Those land uses, public policies, and neighborhood characteristics that existed prior to September 11, 2001 are discussed in this section.

LAND USE AND NEIGHBORHOOD CHARACTER

Project Site

Before September 11, 2001, the Project Site was occupied by the WTC PATH Terminal, which included a track and platform level, an associated mezzanine/fare-zone level, and sub-grade pedestrian connections to adjacent streets, New York City Transit (NYCT) subways, and WTC site developments. The terminal was the busiest of the 13 PATH stations with approximately 67,000 average weekday boardings. Access to the mezzanine and platforms was located on the eastern portion of the Project Site within the WTC Concourse. The track and platform and mezzanine levels were located on the western half of the site, below the WTC Towers 1 and 2. The tracks connected to the Hudson Tubes beneath Route 9A and extended west under the Hudson River to New Jersey. Below ground, remnants of the former Hudson & Manhattan (H&M) Terminal existed in an altered state and were used for parking, truck access, and storage for the other facilities on the WTC site.

The WTC Concourse that housed the WTC PATH Terminal also contained retail stores and a transportation hub providing pedestrian connections to seven subway lines operated by the Metropolitan Transportation Authority (MTA) as well as the PATH trains. Although not particularly successful initially and deserted on weekends for years, the shopping area had been improved and by 2001 had become an extremely lucrative retail hub. Austin J. Tobin Plaza (Tobin Plaza) and the additional outdoor public areas along the east side of Church Street housed the popular Greenmarket and several outdoor cafes, and served as a regular performance venue for free concerts.

Liberty Plaza contained benches, planters, and lighting, providing respite for area workers and visitors. The WFC was connected to the Project Site and the WTC complex by a pedestrian bridge over Route 9A.

Study Area

The project study area was generally characterized by a mixed land use pattern which prevails today. Dominated by the scale of the WTC buildings and their populations, there was a strong and growing residential community in Tribeca and the Financial District, and a number of

institutional uses in addition to offices. The blocks immediately surrounding the Project Site were extremely active and a vital part of the dense commercial core of Lower Manhattan.

WTC Redevelopment Sites. Prior to September 11, 2001, the WTC site contained over 10 million square feet (msf) of office space in five buildings, approximately 500,000 square feet of retail space, a 22-story hotel, and a public plaza. The site was best known for the Twin Towers: One and Two WTC, two 110-story buildings that rose over 1,350 feet. Each tower contained more than 4.1 msf of rentable Class A office space. Between the Towers at the southwest corner of the WTC site was Three WTC, a 22-story Marriott Hotel with 820 rooms and meeting spaces. Along the north and west edges of the WTC site were two nine-story buildings (Four and Five WTC) and the eight-story U.S. Custom House (Six WTC).

The five office buildings and the hotel surrounded Tobin Plaza where concerts and other public events were held. Along Church Street was more plaza area expanded by the southbound lanes of the street that were closed to traffic and improved with benches and planters with trees.

The Twin Towers dominated the Project Site and the surrounding blocks. Area streets and sidewalks bustled with traffic and with pedestrians going to work, shop, sightsee, and travel to other areas. Approximately 48,000 workers were employed at the WTC Redevelopment Sites with 34,000 employees in the Twin Towers alone (see Chapter 5, "Socioeconomic Conditions"). Over 200,000 workers and commuters poured through the WTC each weekday and into the evening hours.

Although weekends were less active, the Twin Towers and retail stores attracted a steady flow of tourists and shoppers. Tourists from around the world came to see and photograph the Twin Towers, to visit the observation deck, and to dine at Windows on the World. Although it was a busy nexus of transportation, which included the WTC PATH Terminal, and an important destination itself, the WTC superblock blocked view corridors and was often a barrier for residents, workers, and visitors of the three distinct neighborhoods surrounding it—Tribeca to the north, BPC to the west, and the Financial District to the east and south.

To the south, the building at 130 Liberty Street was a fully occupied office tower with ground-floor retail. It had a plaza with a fountain in the summer that was replaced by shrubs in the winter. Above this was an additional plaza level originally intended to connect to the plaza level at the WTC. To its west, the block at the corner of Liberty Street and Route 9A was an active parking lot and the site of the St. Nicholas Greek Orthodox Church.

North of WTC site. The area north of the WTC site contained a variety of land uses, including office, residential, institutional, light industrial/utilities, and open space, as well as vacant land. It was a transition zone between the mainly commercial office buildings to the south and the more residential and institutional development in Tribeca to the north. Prior to September 11, 2001, Vesey Street carried substantial vehicular and pedestrian traffic volumes. With the approximately two million-square-foot 7 WTC, the Federal Office Building/U.S. Post Office (90 Church Street), and the Barclay-Vesey Building (Verizon Building), used for housing telephone equipment and offices, lining the north side of Vesey Street between Route 9A and Church Street, these blocks were a vital part of the dense commercial core of Lower Manhattan. A number of additional office buildings, many with ground floor retail uses, were located along Park Place and Murray Street to the north and between Church Street and Broadway to the east.

The renovation of the Borough of Manhattan Community College's (BMCC) Fiterman Hall, located immediately north of Seven World Trade Center (7 WTC), was near completion and actively used.[1] Other institutional uses included P.S. 234 and St. John's University School of Risk Management, Insurance and Actuarial Science, both between Greenwich Street and Route 9A. Located among these educational institutions were two large, vacant parcels known as Site 5B and Site 5C under the Washington Street Urban Renewal Area (WSURA) Plan (see "Pre-September 11, 2001 Baseline Conditions—Public Policy").

The blocks east of Greenwich Street and north of Murray Street had a greater mix of uses more typical of the Tribeca community. They were characterized by smaller commercial and residential buildings with a variety of ground-floor retail uses, including banks, restaurants, dry cleaners, and convenience-goods stores. The retail uses were more heavily concentrated along the north-south streets and Chambers Street, with smaller businesses along the east-west streets. Residential uses were concentrated on Greenwich Street between Murray and Chambers Street, on Murray Street east from Greenwich Street, and on Park Place from West Broadway to the east. In the easternmost portion of the subarea was City Hall Park and City Hall which housed the Mayor's offices and chambers of the New York City Council.

Broadway Corridor. Several buildings with a range of uses were located directly across Church Street from the Project Site. A church (St. Paul's Chapel), a hotel (the Millennium Hotel), a department store (Century 21), and a massive office building (1 Liberty Plaza) covering almost its entire block lined Church Street from Vesey to Liberty Streets. Across Liberty Street to the south was Liberty Park Plaza, part of the Project Site.

Office and other commercial uses generally dominated the Broadway Corridor before September 11, 2001. It was part of the historic financial district, the traditional home of financial institutions and corporate headquarters and the smaller businesses and industries which serve them. Class A and B office buildings lined Broadway as well as Church Street/Trinity Place and Nassau/Broad Streets. Such notable buildings as 140 Broadway, the Bank of New York Building, and the New York Stock Exchange were located here. Residential buildings with retail use at street level were concentrated in the northern portion of the corridor east of Broadway. Heavy vehicular and pedestrian traffic, especially along Church Street and Broadway, were typical throughout the weekday and into the evening hours.

Greenwich South Corridor. The area south of the WTC site contained a mix of land uses on blocks of varying sizes, including residential, office, educational, and public parking as well as the entrance and exit ramps for the Brooklyn Battery Tunnel. The area was densely developed with buildings generally occupying their entire lots and public plazas non-existent.

The New York City Fire Department (FDNY) firehouse for Ladder Company 10 and Engine Company 10 stood at the corner of Liberty and Greenwich Streets. To its east were residential uses in converted commercial buildings with active ground-floor retail uses, and a fast-food restaurant building. West of Greenwich Street, the 39-story office tower at 130 Liberty Street dominated the block. A public parking lot and St. Nicholas Greek Orthodox Church occupied the block to the west along Route 9A. Farther south, the buildings at 90 West Street and 130 Cedar Street were used as commercial office space. The building at 19 West Street was occupied by the Downtown Athletic Club, a private health club with hotel rooms and the home of the Heisman Trophy.

[1] BMCC's main campus is located four blocks to the north along Route 9A in the Tribeca subarea.

A number of commercial buildings both large and small south of Cedar Street between Route 9A and Greenwich Street had been or were in the process of being converted to residential use, following an ongoing trend in Lower Manhattan that began in the 1990s. Office uses were also located throughout the corridor with several buildings between Washington Street and Trinity Place, including the American Stock Exchange, the Trinity Building, and 40 Rector Street. Other commercial uses included restaurants, informal eating establishments, clothing stores, and small-scale retail businesses concentrated along Greenwich and Washington Streets, with limited retail along Route 9A.

Institutional uses included two schools and a religious organization. The High School for Leadership and Public Service and the High School of Economics and Finance were both on Trinity Place near Thames Street. Occupying the historic Downtown Community House on Washington Street north of Rector Street was the True Buddha Diamond Temple of New York. The corridor also contained several public parking structures, including the massive Battery Garage. Extending from Route 9A to Greenwich Street near the Brooklyn Battery Tunnel ramps, the garage could accommodate more than 2,000 vehicles.

Battery Park City. BPC, one of New York City's newest neighborhoods, is a "city within the city" that was still being completed before September 11, 2001. Built in part on landfill from the large volume of soil excavated for the WTC complex, BPC is a mixed-use community with a commercial center, two residential neighborhoods, schools, cultural facilities, hotels, and neighborhood amenities such as dry cleaners, grocery stores, shopping opportunities, movie theatres, and restaurants, as well as the most extensive open space network in Lower Manhattan.

BPC was generally divided into three sections: the North neighborhood (north of Vesey Street), the World Financial Center (WFC), and the South neighborhood (south of Liberty/Albany Streets). All three sections were bound together by a common scale and style and by the extensive waterfront parks and public esplanade, which began at Battery Park in the south and extended along the Hudson River to just north of Chambers Street at the north end. BPC was physically divided from the WTC site and the other subareas by Route 9A. This eight-lane divided highway served as a major thoroughfare along Manhattan's west side and provided access to the Brooklyn-Battery Tunnel. The highway also contained a separate Class I bikeway and walkway, part of the Hudson River Park, for bicycles, pedestrians, and recreational users.

Buildings in the North neighborhood were generally newer and taller, with several vacant parcels between Vesey and Warren Streets. The residential buildings at 20 and 22 River Terrace were under construction. Street-level activity was light in this area. However, the presence of Stuyvesant High School and P.S./I.S. 89 increased the level of activity during daytime hours.

The WFC consisted of four large office towers with retail shops and restaurants, and the Winter Garden, a large, glass-enclosed public atrium. These buildings were strategically positioned to tie into the WTC complex which stood directly across Route 9A. Two pedestrian bridges connected the WFC with the WTC complex to the east.

The South neighborhood contained mostly low- and mid-rise residential buildings in addition to cultural and hotel uses. With the exception of two large vacant parcels along Route 9A, the South neighborhood was fully developed. The Ritz-Carlton Hotel was approaching its scheduled opening, and construction of the Jewish Museum Expansion was underway.

Tribeca. Residential and commercial uses dominated the Tribeca neighborhood, with institutional, industrial, and open space uses also present throughout the subarea. Late 19th and early 20th century corniced loft buildings were interspersed with new mid-rise apartment

buildings with terraces and bay windows that seek to evoke the style of the older buildings. High-rise buildings were primarily located along the wider north-south streets with smaller buildings occupying the midblocks. Many of the smaller commercial buildings were converted to residential use with loft-style apartments and a variety of ground-floor retail uses. These included basic neighborhood amenities, such as banks, dry cleaners, and convenience goods stores, as well as large concentrations of art galleries, boutique shops, bars, and restaurants.

Notable institutional uses included the main campus of BMCC (also home to the Tribeca Performing Arts Center), New York Law School, and the Tribeca Film Center. Office buildings were concentrated along Broadway and Worth Street, with a large office complex situated on the block bound by Route 9A and North Moore, Hubert, and Greenwich Streets. Some of the industrial uses that characterized the neighborhood before the residential conversions began were still present in the northwestern portion of the study area, mainly in the area bounded by West, Greenwich, Laight, and Canal Streets. Open spaces included Washington Market Park at Chambers and Greenwich Streets, a 1.65-acre public landscaped park with active recreation areas for children. The Hudson River Park included a permanent bicycle and pedestrian greenway running up the west side of Manhattan, with interim uses on the piers and waterfront offering volleyball, minigolf, basketball courts, batting cages, concessions, a boathouse, and fishing and passive use areas.

The subarea had a slightly irregular street pattern, with heavy north-south traffic, particularly along Route 9A and all around St. John's Rotary which provided access to the Holland Tunnel. With such a diversity of uses, pedestrian activity was steady during the day and evening throughout much of the subarea.

Chinatown below Canal Street. The Chinatown below Canal Street subarea included mainly commercial and residential uses in small, older buildings, and large residential towers. High concentrations of commercial and mixed-use buildings existed throughout the subarea, concentrated along Canal Street, between Broadway and Pearl Street, and along the north-south streets throughout the subarea. Restaurants, fresh food markets, tea and rice shops, and garment factories are the main businesses in Chinatown, and the area's distinct character and mix of businesses made it a popular tourist destination. The largest Asian community in North America could be found among the narrow streets of Chinatown, a neighborhood which extends north of Canal Street beyond the study area.

The eastern and southern sections of the subarea included large-scale residential developments, such as Chatham Towers, the Governor Alfred E. Smith Houses along the East River, Knickerbocker Village, and Confucius Plaza, a large, middle-income residential building at the Bowery and Division Street.

Additional uses in the subarea included institutional, transportation, office, and open space. Three elementary schools and numerous religious institutions were scattered throughout the area. Cultural institutions included the Museum for Chinese in the Americas at Mulberry and Bayard Streets, and the Eldridge Street Project between Canal and Division Streets, which undertook a massive restoration of the Eldridge Street Synagogue, a National Historic and New York City Landmark. Columbus Park between Baxter and Mulberry Streets and a number of ballfields near the Manhattan Bridge at the East River were all well-utilized open spaces.

Civic Center. The Civic Center subarea was characterized by a high concentration of government and government-related uses, including several courthouses, city and state government office buildings, and the New York Police Department headquarters as well as their

office uses. Several small parks were located near the courthouses as well as a small portion of the African burial ground, located along Duane Street east of Broadway. The historic courthouse buildings lined Center Street, the area's main thoroughfare, which passed through Foley Square. The ramps to the Brooklyn Bridge created a physical and visual barrier to the neighborhoods to the south.

Brooklyn Bridge to Battery Park. This subarea comprises the eastern section of the Financial District and was largely commercial, with pockets of residential, institutional, entertainment, and open space uses. The area between Wall, Pearl, and Whitehall Streets is where New York City began and where Lower Manhattan's reputation as a major international economic hub was born. Huge skyscrapers housing financial service institutions, law firms, and insurance companies tower over narrow, winding streets in the Wall Street area. Large commercial buildings dating from the early 1930s include 70 Pine Street, 40 Wall Street, and 20 Exchange Place. More modern office buildings include One Chase Manhattan Plaza, 55 Water Street, One New York Plaza, and Financial Square.

The area's historic significance combined with a large presence of cultural institutions, including Federal Hall, the South Street Seaport Museum, and Castle Clinton National Monument, which provided ferry connections to the Statue of Liberty and Ellis Island Immigration Museum, made this area a major tourist destination. A greater mix of uses was present in the northern portion of the subarea, including several residential buildings and institutional uses. The largest residential use in the area was Southbridge Towers, located on the superblock bounded by Gold, Fulton, and Water Streets, and the Brooklyn Bridge. The area surrounding these towers contained small concentrations of residential buildings, most with ground-floor commercial uses. Major institutional uses included Pace University and NYU Downtown Hospital, located just south of the Brooklyn Bridge.

The South Street Seaport was a dominant use along the East River waterfront, attracting large numbers of visitors to shop, restaurants, boat rides, and boardwalk entertainment. At the southern tip of Manhattan, the Whitehall Ferry Terminal provided access to the Staten Island Ferry. Adjacent to it and encompassing 23 acres along the waterfront was Battery Park. The park contained expansive lawns and landscaping, a waterfront promenade, playgrounds, several monuments and memorials, and cultural programs.

The eastern edge of the study area included Franklin D. Roosevelt Drive (FDR Drive) and Water Street, two roadways that carried heavy volumes of local and through traffic. Streets were crowded during the workday with large numbers of office workers, as well as tourists and a growing number of residents. The area was substantially less active during evening hours and on weekends.

PUBLIC POLICY

Since office vacancy rates began to increase in Lower Manhattan in the early part of the 1990s, public policy has been used to influence land use and has begun to bring about the transformation of the Financial District into a more diverse, 24-hour community. Policy initiatives were developed beginning in 1995 to offer economic and financial incentives intended to increase office occupancy as well as promote reinvestment and adaptive reuse of the more obsolete buildings in Lower Manhattan. The policies were designed to lower the area's commercial vacancy rates, convert targeted commercial office buildings into residential space, help build a 24-hour, mixed-use neighborhood, invest in and upgrade Class B office space, and attract new retailers to the area.

Many of the public policies in effect today to support Lower Manhattan as a vibrant, attractive residential community as well as a center of business and tourism were in place prior to September 11, 2001. The only policy in effect prior to September 11, 2001, that is not in effect today is the Washington Street Urban Renewal Area (WSURA). Each of these policies is described below. Those policies specifically created in response to the terrorist attacks are discussed in the following section (see "Changes in the Affected Environment Since September 11, 2001—Public Policy").

Zoning

While zoning regulations do not apply to a large portion of the Project Site itself, they are applicable to the land use study area generally. Therefore, a brief discussion of zoning is included to further establish the context of the Preferred Alternative.

The Project Site is located in an area zoned C6-4 and C5-3 and falls within the boundary of the Special Lower Manhattan District (see Figure 4-2 and Table 4-1). The surrounding area located in Liberty Park Plaza is zoned C5-5, a high-density restricted central commercial district intended for retail and large offices, as well as high-density residential and community facilities. The open plaza was constructed as part of the development of 1 Liberty Plaza, a large office building to the immediate north. The surrounding area located at the WFC is zoned under the Special BPC District, described below.

The entire approximately 16-acre WTC site is owned by PANYNJ. The 1962 legislation authorizing the development of the WTC provides that so long as the WTC is owned by PANYNJ, no agency, commission, or municipality shall have jurisdiction over the WTC. The New York City Zoning Resolution, Building Code, and Fire Code do not therefore apply to the WTC site, including the Project Site. However, it is PANYNJ policy to voluntarily conform to the maximum extent practicable to local building and fire codes. This policy is evidenced by the various Memoranda of Understanding (MOUs) that PANYNJ has entered into with the City's Department of Buildings and Fire Department. These MOUs establish the policy of PANYNJ to ensure that its facilities meet code requirements to the maximum extent practicable and, where appropriate, exceed them.

Table 4-2 summarizes the existing zoning districts located throughout the larger study area. The North of WTC Site, Broadway Corridor, and Greenwich South Corridor subareas are largely zoned for medium- and high-density commercial office development. The Project Site is surrounded by General Central Commercial (C6) districts to the north and south, as well as Restricted Central Commercial (C5) districts to the north and east. The C6 districts are zoned for a wide range of retail, office, amusement, service, custom manufacturing, and related uses normally found in the central business district. These districts typically contain corporate headquarters, large hotels, entertainment facilities, and some residential development, with ground-floor retail uses in some buildings. The C5 districts, found in the Broadway Corridor and portions of the Greenwich South Corridor and North of WTC site subareas, are designed to provide for office buildings and a great variety of retail stores.

Table 4-1
Study Area Zoning

Zoning District	Permitted Uses/Bulk
Commercial Districts	
C2-8	Low-density neighborhood shopping/services. High-density residential and community facility use.
C4-6	Medium-density general commercial (such as department stores and theaters). High-density residential and community facility.
C5-3, C5-5	High-density restricted central commercial district intended for retail and large offices. High-density residential, community facility.
C6-1, C6-2, C6-3	Medium-density general central commercial outside CBD. Low- to medium-density residential and community facility.
C6-1G	Medium-density general central commercial district. Allow residential conversion of non-residential floor area only by special permit.
C6-2A, C6-3A	Contextual* medium-density general central commercial district outside CBD. Low- to medium-density residential and community facility.
C6-4, C6-9	High-density general central commercial intended for CBD, allowing medium- to high-bulk offices. High-density residential, community facility.
C6-4A	Contextual high-density general central commercial intended for CBD, allowing medium- to high-bulk offices. High-density residential, community facility.
C8-4	General service district intended to provide for necessary service establishments often involving objectionable influences (noise from operations or truck traffic). Incompatible with residential and retail uses.
Residential Districts	
R7-2	Medium-density residential, community facility.
R8	General residence district. High-density residential, community facility.
Manufacturing Districts	
M1-4	Low-density light industrial uses (high performance) and certain community facilities.
M1-5, M1-6	Medium-density light industrial uses (high performance) and certain community facilities (for loft areas).
M2-3	Low-density general industrial uses (medium performance), most commercial uses.
Special Purpose Districts	
LM	Special Lower Manhattan District
TMU	Special Tribeca Mixed-Use District
BPC	Special Battery Park City District
TA	Special Transit Land Use District

Note: * Contextual districts mandate street wall heights, lot coverage and density requirements, which produce lower, bulkier buildings that maintain the scale and street space of the existing neighborhoods.

Table 4-2
Zoning Districts by Subarea

Subarea	Zoning Districts
WTC Redevelopment Sites (Adjacent Sites only)	C6-9, Special Lower Manhattan District, Special BPC District
North of WTC site	C5-3, C6-2A, C6-3, C6-3A, C6-4, Special Tribeca Mixed-Use District, Special Lower Manhattan District
Broadway Corridor	C5-3, C5-5, Special Lower Manhattan District
Greenwich South Corridor	C5-5, C6-9, Special Lower Manhattan District
Battery Park City	Special BPC District
Tribeca	C6-2A, C6-3A, C6-4, C6-4A, M1-5, M1-6, M2-3, Special Tribeca Mixed-Use District
Chinatown below Canal Street	C2-8, C6-1, C6-1G, C6-4, C6-4A, C8-4, R7-2, M1-4, M1-5, M1-6, Special Transit Land Use District
Civic Center	C6-1, C6-4
Brooklyn Bridge to Battery Park	C2-8, C4-6, C5-3, C5-5, C6-9, R8, M1-4, Special Lower Manhattan District

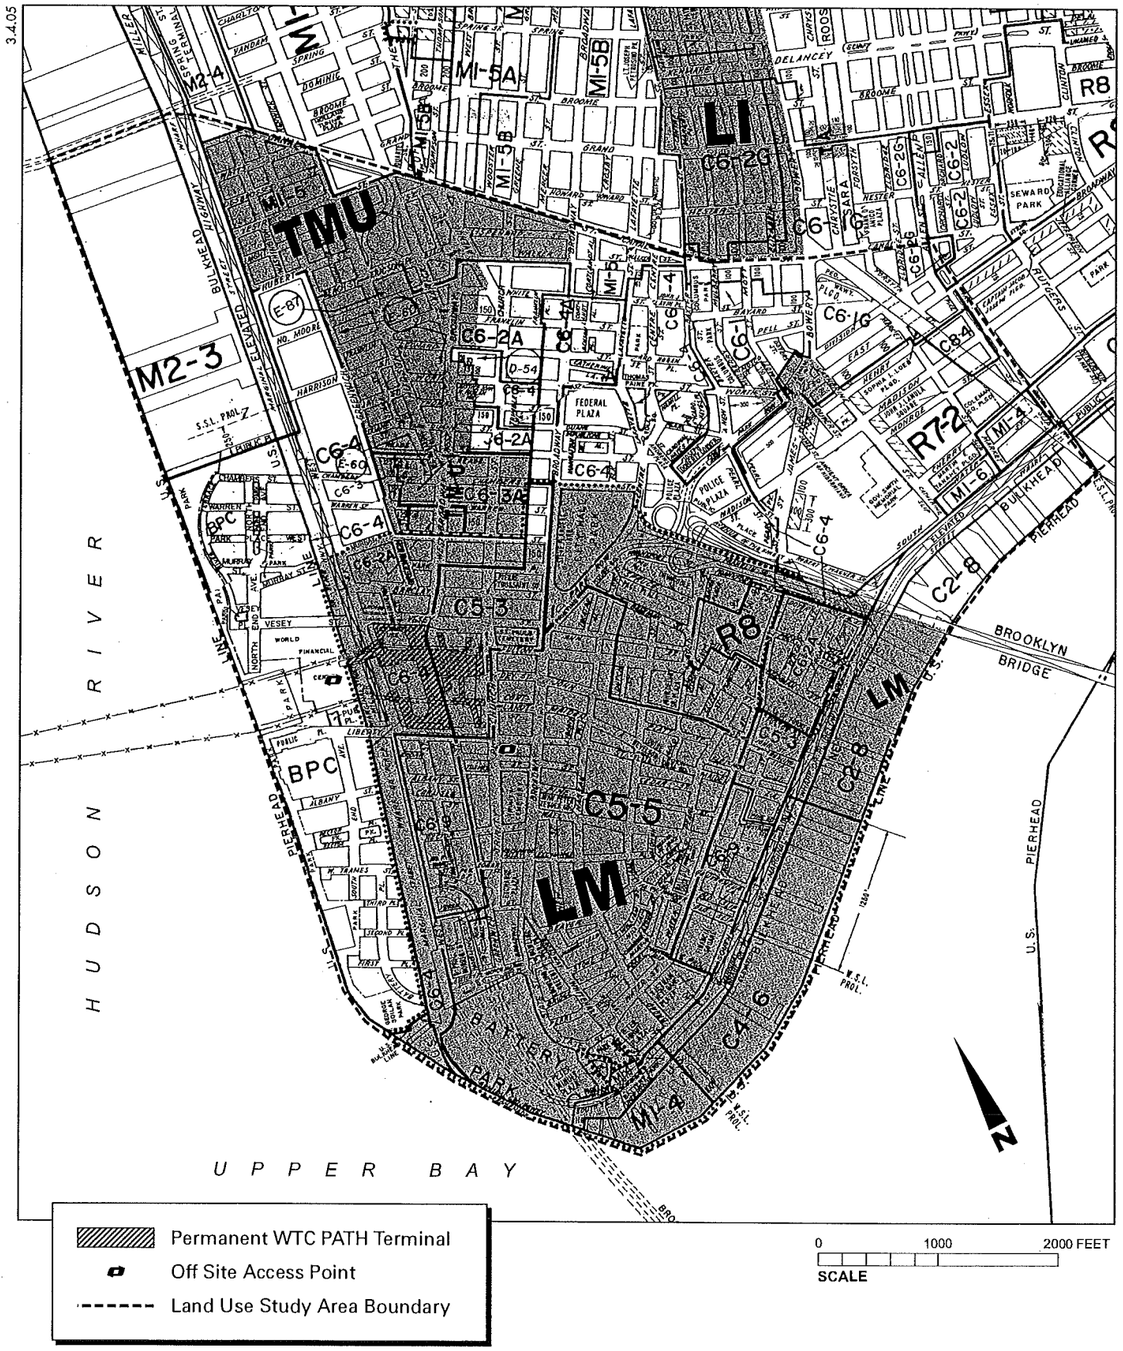

Figure 4-2
Zoning Map

Tribeca is primarily zoned with medium-density commercial districts (C6), with manufacturing districts (M1 and M2) mapped in the north and west sections of the subarea near Canal Street and along the Hudson River waterfront. The Chinatown below Canal Street subarea contains commercial (C6 and C8), manufacturing (M1), and residential (R7) zoning districts. The C6-4 zoning district encompasses nearly the entire Civic Center subarea allowing for medium- to high-bulk office buildings. The Brooklyn Bridge to Battery Park subarea is primarily zoned with medium- and high-density commercial districts (C5 and C6), with low- to medium-density districts (C2-8 and C4-6) mapped along the East River waterfront. In addition, the R8 residential district is mapped specifically for the Southbridge Towers residential development just south of the Brooklyn Bridge. With the exception of the manufacturing districts along the waterfront, zoning districts throughout the study area permit residential uses.

In addition to the underlying zoning, three special districts cover portions of the study area: the Special Lower Manhattan District, the Special BPC District, and the Special Tribeca Mixed-Use District.

Special Lower Manhattan (LM) District. The Project Site and a large portion of the surrounding study area lie within the Special LM District. Established in 1998, it covers the country's third-largest central business district including all of Lower Manhattan generally south of Murray Street and the Brooklyn Bridge. It was created to simplify and consolidate the overlapping complex regulations previously governing Lower Manhattan, to allow the area to grow while reinforcing its historic character and built fabric, and to facilitate the change to a mixed-use community. The zoning change relaxed strict use controls that had inhibited the retail, entertainment, and service establishments generally needed to support a 24-hour community. New height and setback controls also allow considerable design flexibility and, at the same time, are intended to encourage new development that would be consistent with the historic character of Lower Manhattan.

Special Battery Park City District. That portion of the Project Site located at the WFC and BPC as a whole are governed by the Special BPC District. The Special BPC District was established by the city and the BPCA in 1973 to guide development in accordance with the BPC Master Plan. Elements of the Master Plan include a central office complex flanked by residential neighborhoods to the north and south, and a continuous, publicly accessible esplanade along the Hudson River waterfront. The district contains special design controls with respect to floor area ratio (FAR), required building walls, and permissible building height.

Zoning text modifications for the special district occurred in 1981, 1987, and 2001. The BPC District is divided into three subdivisions: Zone A, Zone B, and Zone C. Zone A provides for residential development with ancillary retail and service uses and hotels. Zone B, which encompasses the WFC and the New York Mercantile Exchange Building, provides for commercial and mixed-use development with ancillary retail and service uses. Zone C provides for commercial and mixed-use development, parking, and ancillary retail and service uses.

Special Tribeca Mixed-Use (TMU) District. The Special TMU District covers the area from Greenwich Street to the west of West Broadway and from north of Harrison Street to Murray Street, and includes portions of the Tribeca and North of WTC site subareas. It is intended to retain stable industries within the Tribeca neighborhood that provide jobs and adequate wages and to encourage stability and growth by permitting controlled residential uses and light manufacturing to coexist. In addition, the district aims to facilitate the change to a mixed-use community and permit the area to grow while protecting its historic character.

World Trade Center Act of 1962

In 1962, the States of New York and New Jersey enacted legislation which authorized PANYNJ to undertake a port development project consisting of 1) the WTC, 2) the Hudson Tubes, and 3) certain extensions of the Hudson Tubes. PANYNJ was authorized to cooperate with other government agencies in the rehabilitation and redevelopment of the WTC and Hudson Tubes for the purpose of renewal and improvement of these areas as part of the port development project. The legislation provided for PANYNJ to acquire, rehabilitate, and operate the rail transit property associated with the Hudson Tubes either directly or through a wholly owned subsidiary corporation. Accordingly, PANYNJ established the Port Authority Trans-Hudson (PATH) Corporation, which acquired, by condemnation, the railroad and equipment owned by the H&M Railroad Company, including the Hudson Terminal Building in Lower Manhattan.

Lower Manhattan Economic Revitalization Plan

The Lower Manhattan Economic Revitalization Plan was the center of public policy initiatives that generated new economic activity in Lower Manhattan. This plan was enacted into law in 1995 and has been extended until June 30, 2007. The plan includes benefits for both commercial tenants and residential conversions, as well as other cost-savings programs. Commercial tenant benefits include a five-year real estate tax abatement and a commercial rent tax special reduction. Both programs are applicable for pre-1975 commercial buildings with leases executed prior to March 31, 2001. The program benefits are required to pass through to commercial tenants. A residential conversion program is also available for a 100 percent exemption of the increased assessed value due to residential conversion for 8 years (9 years for landmarked buildings) and phased in at 20 percent every year for 4 years thereafter, for a total of 12 years. In addition to tax incentive benefits, the plan includes a 12-year energy program consisting of a reduction of electricity costs. The plan attracted traditional Lower Manhattan commercial tenants and multi-media, entertainment, and technology entrepreneurs, creating a new Information Technology District in the area.

The Alliance for Downtown New York

The Alliance for Downtown New York (Downtown Alliance), the city's largest Business Improvement District (BID), was established in 1995. Generally, a BID delivers supplemental services such as sanitation and maintenance, public safety and visitor services, marketing and promotional programs, capital improvements and beautification in a designated area. BIDs are funded by a special assessment paid by property owners within the district. The Downtown Alliance's mission is to transform Downtown into a 24-hour neighborhood and to create a safe, clean, live-work, wired community for the 21st century. The BID covers the area from City Hall to the Battery and from the East River to Route 9A, and includes approximately 100 msf of office space and over 100 city blocks.

Battery Park City Authority

The BPCA is a public benefit corporation created in 1968 by Governor Nelson Rockefeller and the New York State Legislature to develop and operate the 92-acre landfill at the southwestern tip of Manhattan known as BPC. Parcels of land are leased to private developers who build in accordance with BPCA guidelines, as described above (see "Special BPC District").

Hudson River Park Trust

In 1998, the Hudson River Park Act created the Hudson River Park Trust (HRPT) and established the boundaries for the Hudson River Park. HRPT is a public benefit corporation under the jurisdiction of both the City and the State that is responsible for developing and operating the Hudson River Park, which extends from Battery Park to West 59th Street, where it connects with Riverside Park. The 5-mile, 550-acre park, much of which is in construction, will be built in six segments. When complete, Hudson River Park will consist of 13 park piers, a continuous waterfront esplanade, active and passive recreation space, boating, and three commercial development nodes.

The portion of the park opposite the Project Site and as far north as Chambers Street is Segment 2. Segment 3, located in the Tribeca subarea, runs from Chambers Street to north of Canal Street and includes Piers 25, 26, 32, and 34.

Local Waterfront Revitalization Program

The Project Site is located within the boundaries of the coastal zone. Pursuant to federal legislation, in 1999 and 2002, New York City and State, respectively, adopted policies aimed at protecting resources in the coastal zone. New York City's Waterfront Revitalization Program (WRP) contains 10 major policies, each with several objectives focused on improving public access to the waterfront; reducing damage from flooding and other water-related disasters; protecting water quality, sensitive habitats, such as wetlands, and the aquatic ecosystem; reusing abandoned waterfront structures; and promoting development with appropriate land uses. The principles of the WRP formed the basis for a NYCDCP study and the resulting adoption of new waterfront zoning. For City actions, the New York City Planning Commission (CPC) certifies whether a proposed action is in compliance with the City's WRP. The New York State Department of State (NYSDOS) or the applicable state agency has this responsibility on the state level. Chapter 14, "Coastal Zone Management," provides a detailed analysis of the compatibility of the Preferred Alternative with the 10 WRP policies.

421-g Program

The 421-g program provides a real estate tax exemption and abatement incentive for developers to convert commercial buildings, generally south of Murray and Frankfort Streets, into residential dwellings. Up to 25 percent of the converted building may contain commercial, community facility or accessory use space, with the tax exemption reduced proportionally if the total nonresidential space exceeds 12 percent of the aggregate floor area. The program generally provides for a 14-year exemption from the increase in real estate taxes resulting from the work and abatement of substantially all existing real estate taxes on the site. Since 1998, more than 50 buildings in the study area have been converted from office to residential use under the 421-g program.

Washington Street Urban Renewal Area

The city established WSURA in 1961; it expired on January 25, 2002. The WSURA Plan's stated objective was to promote diversified and economically sound development in the area from Barclay to Hubert Streets, between Greenwich Street and Route 9A. Originally, the plan called for development of commercial, light manufacturing, or warehouse uses, but after being amended nine times, the plan called for community space and residential or office development. Today, Sites 5B and 5C between Chambers, Greenwich, and Murray Streets and Route 9A are the only two WSURA sites that remain undeveloped.

CHANGES IN THE AFFECTED ENVIRONMENT SINCE SEPTEMBER 11, 2001

This section provides a detailed description of those land uses and public policies in the land use study area which have changed since September 11, 2001. These differences are largely concentrated on the Project Site, the WTC site, and the subareas immediately surrounding these sites. The land uses and public policies which characterize the Project Site and surrounding study area today form the basis for future land use projections and public policy as well as the basis for the impact analysis which follows. This section highlights those land uses which have changed as a direct result of the terrorist attacks along with any other changes which have occurred, including new construction, conversions, and vacancies, and the effect of such changes on neighborhood character and public policy. Figure 4-3 shows a land use map for the study area as it exists today.

LAND USE AND NEIGHBORHOOD CHARACTER

Loss of the WTC complex left Lower Manhattan without PATH train service to New Jersey due to the destruction of the WTC PATH Terminal and reduced the amount of commercial office space by approximately 13.3 msf, including over 10 msf on the WTC site itself. A substantial number of residents and businesses were displaced by the attacks, and the events resulted in the loss or relocation of hundreds of corporations, small businesses, and retail and office establishments. Except for the Project Site, the WTC Redevelopment Sites, and the immediately surrounding blocks, land use and neighborhood character remain much the same today as they were prior to September 11, 2001. Those buildings which were destroyed or severely damaged as a result of the attacks of September 11, 2001, and its aftermath are listed in Table 4-3. Figure 4-4 shows those parcels with changes to land use since September 11, 2001.

Table 4-3
Affected Buildings

Building/Address	Pre-September 11 Use	Current Status
WTC PATH Terminal	Transportation	Destroyed
1-6 WTC	Office-Retail-Hotel	Destroyed
WFC 1-3	Office-Retail	Repaired and Reopened
WFC Winter Garden	Public Atrium	Rebuilt and reopened
Barclay-Vesey Building (140 West Street)	Utilities-Office	Partially reopened; undergoing renovations
7 WTC	Office	Destroyed; new building under construction
Federal Office Building/U.S. Post Office (90 Church Street)	Office-Institutional	Closed for renovations
Fiterman Hall (30 West Broadway)	Educational	Closed; planned for demolition and rebuilding
Millennium Hotel	Hotel	Renovated and reopened
Century 21	Retail	Renovated and reopened
1 Liberty Plaza/Brooks Brothers	Office-Retail	Renovated and reopened
106 Liberty Street	Restaurant	Renovated and reopened
110 Liberty Street	Residential	Renovated and reoccupied
114 Liberty Street	Residential	Vacant; undergoing renovation
125 Cedar Street	Residential	Renovated and reoccupied
FDNY Liberty Street Firehouse	Institutional	Rebuilt and opened
130 Liberty Street	Office	Vacant; planned for demolition
St. Nicholas Greek Orthodox Church	Institutional	Destroyed
130 Cedar Street	Office	Vacant
90 West Street	Office	Vacant; planned for conversion to residential use

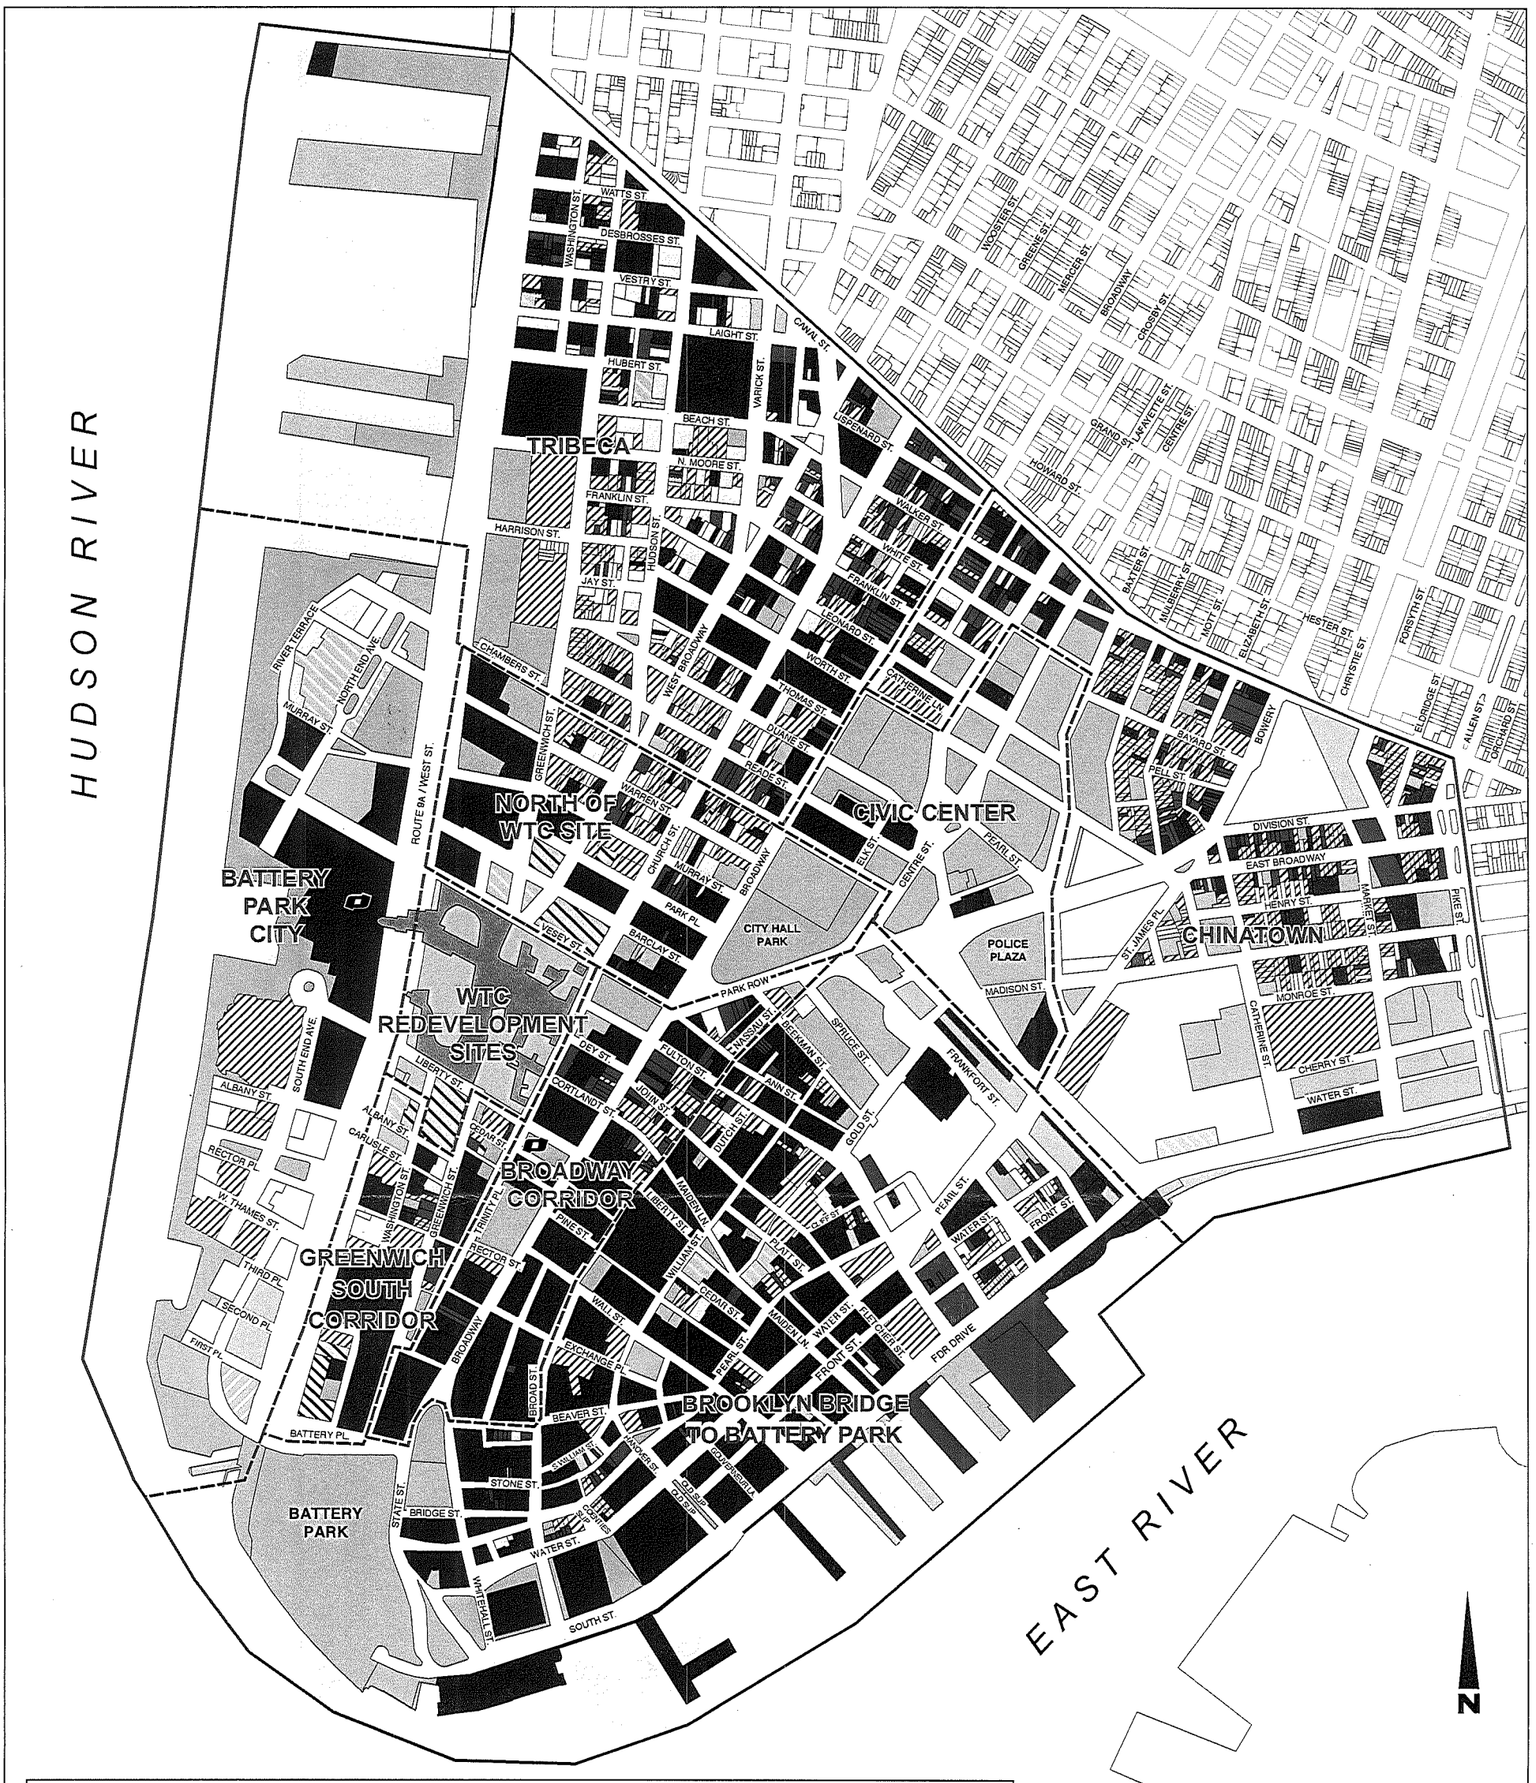

Figure 4-3
Existing Land Use (January 2004)

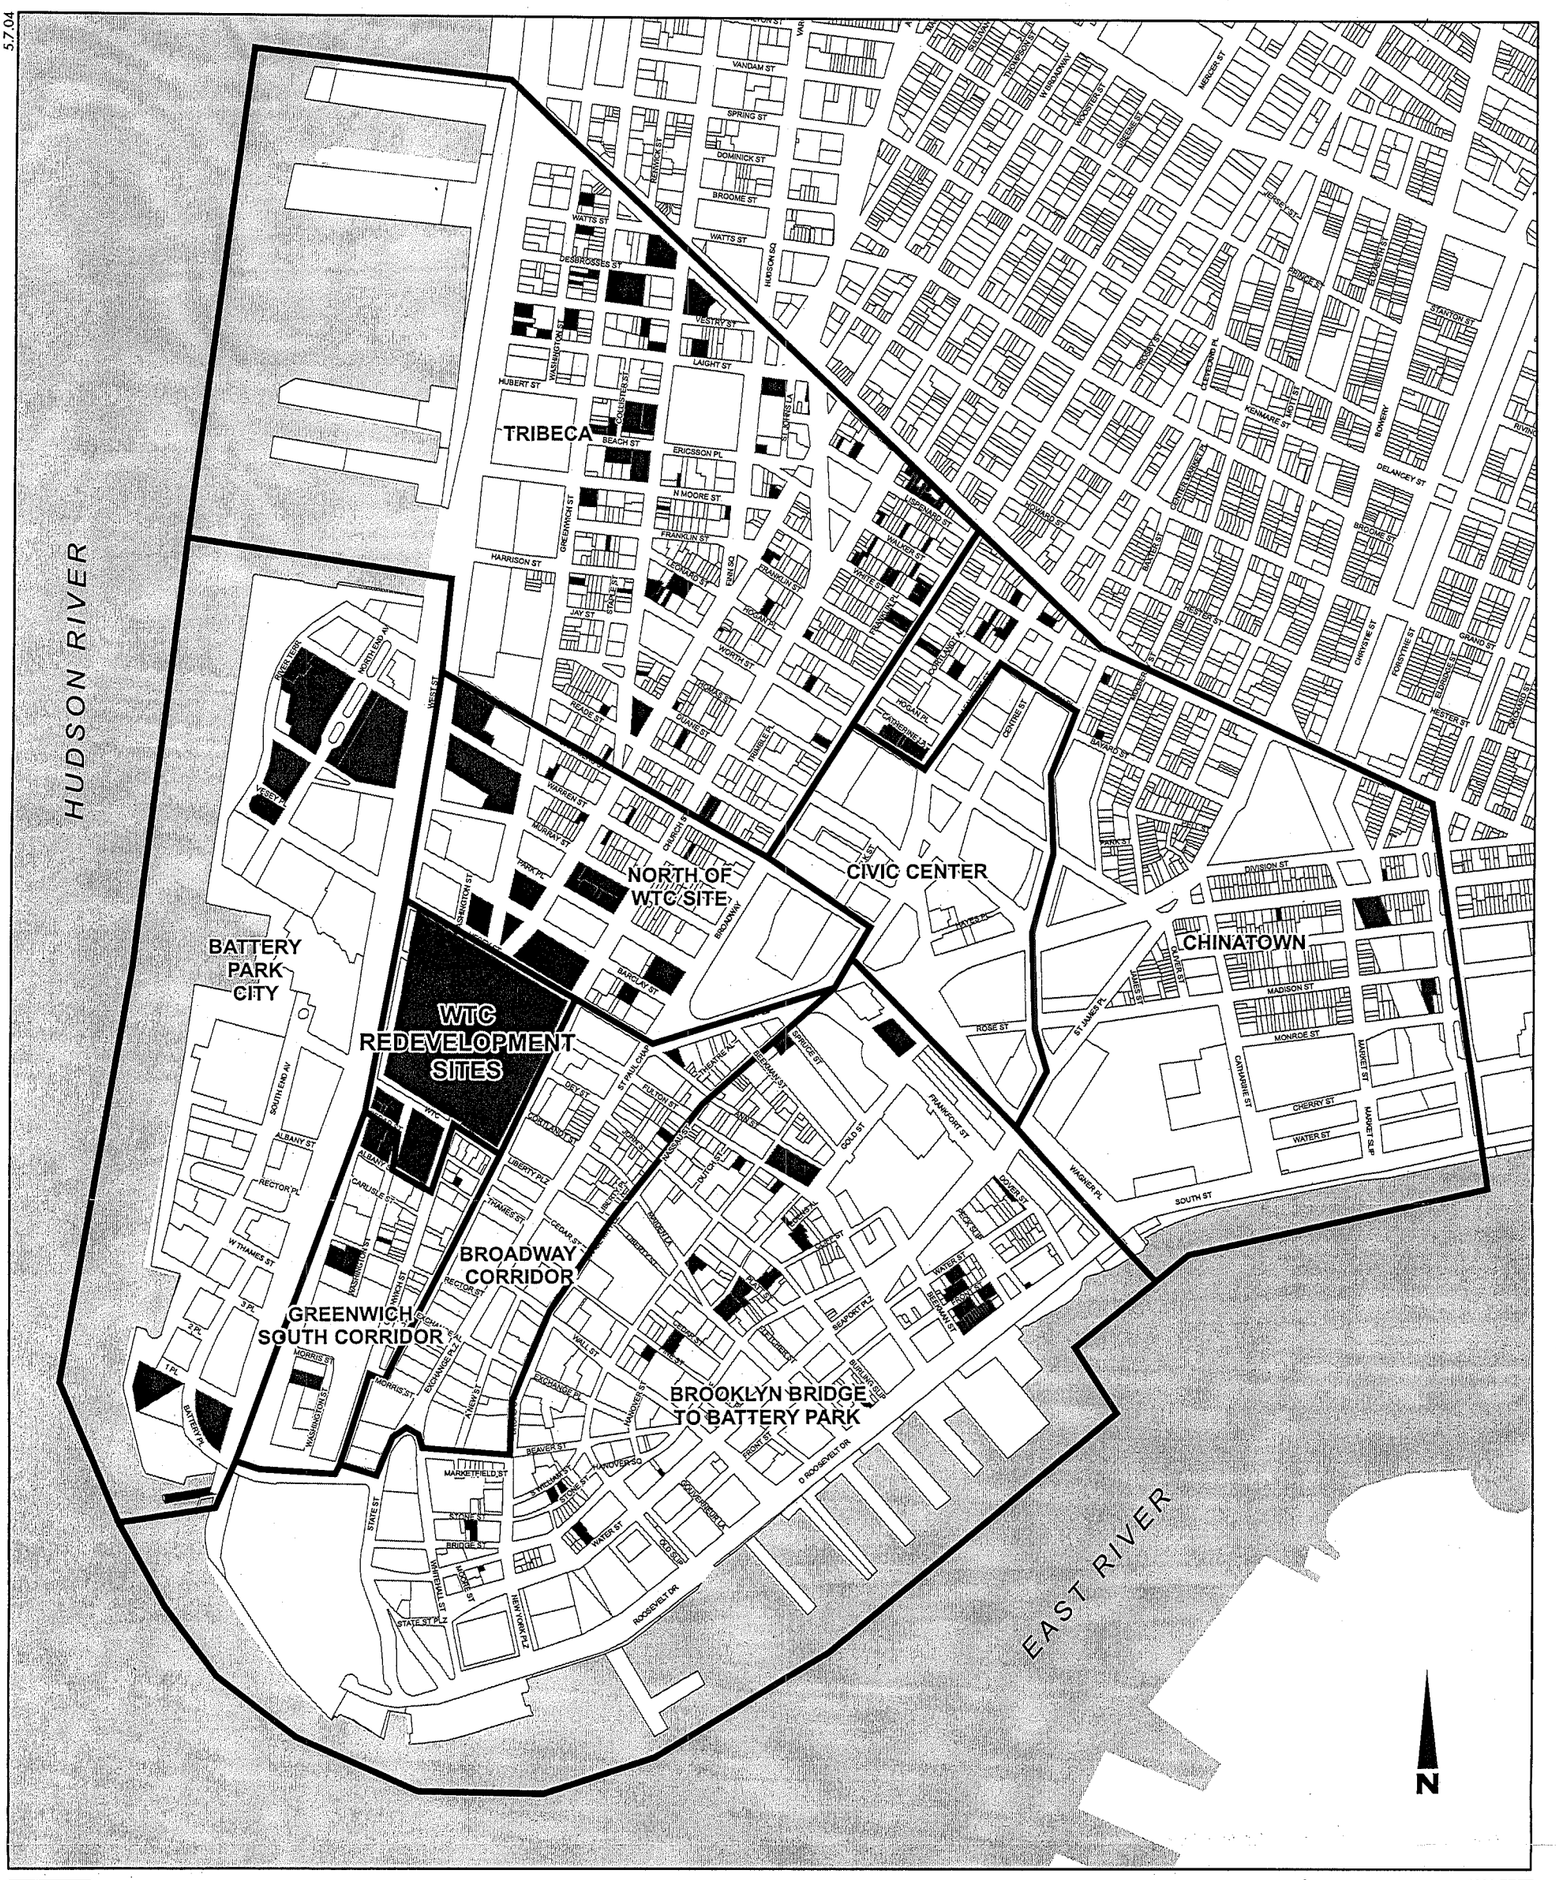

Figure 4-4

Parcels with Changes in Land Use Since September 11, 2001

In addition to the buildings damaged or destroyed as a result of the terrorist attacks, notable changes to land use in the study area since September 11, 2001 include:

- Construction of temporary WTC PATH station.
- Reconstruction of IRT No. 1/9 subway lines through the WTC site.
- Residential conversions continued throughout the study area, concentrated in the North of WTC Site, Tribeca, and Brooklyn Bridge to Battery Park subareas.
- New residential construction in the Battery Park City North neighborhood and the Brooklyn Bridge to Battery Park subarea. Construction has begun on several additional buildings.
- Completion of several cultural institutions in Battery Park City (Skyscraper Museum, Jewish Museum Expansion, and Irish Hunger Memorial), and the opening of Millennium High School at 75 Broad Street in the Brooklyn Bridge to Battery Park subarea.

Project Site

The attacks of September 11, 2001 destroyed the WTC PATH Terminal along with the Twin Towers and the rest of the WTC complex. Today, the temporary WTC PATH station, which opened in November 2003, occupies a large portion of the Project Site. The station entry plaza and canopy occupy the west side of Church Street at Fulton Street on the eastern portion of the Project Site. The rebuilt IRT No. 1/9 subway lines also cross through the eastern portion of the site. The temporary WTC PATH station's mezzanine level, station platforms, and rail tracks are located on the western portion of the site. The rest of the Project Site remains vacant or under construction, and is not accessible to the public.

Liberty Park Plaza is generally open to the public for passive recreational use after being closed for many months after September 11, 2001. The plaza is now the site of the Greenmarket that used to operate across Church Street at the WTC. The Winter Garden at the WFC was reconstructed after suffering severe damage on September 11, 2001.

Study Area

WTC Redevelopment Sites. Each of the Twin Towers was struck on September 11, 2001, by a terrorist hijacked airline jet. Within hours, the Twin Towers collapsed onto the WTC and surrounding areas, causing massive death and devastation. Today, the WTC site is vacant except for the temporary WTC PATH station, the IRT No. 1/9 subway lines crossing the site, and ongoing construction activity. Except for the temporary WTC PATH station and a newly constructed sidewalk/viewing area on the west side of Church Street at the edge of the WTC site, the site is fenced off and not accessible to the public.

The north façade of the office tower at 130 Liberty Street was severely damaged in the attacks of September 11, 2001, and its two-level plaza was completely destroyed. The building stands shrouded in protective black netting and is slated for demolition. To its west, the St. Nicholas Greek Orthodox Church was destroyed and the block on which it stood remains vacant and part of the staging area for ongoing construction activities at the WTC site.

North of WTC Site. Directly across Vesey Street from the WTC site, office buildings were damaged or destroyed on September 11, 2001. In the center, 7 WTC is being rebuilt on the block bounded by Vesey, Barclay, and Washington Streets and West Broadway. It will replace the two Consolidated Edison Company of New York, Inc. (Con Edison) electrical substations and most of the Class A office space that formerly occupied the site. The new building is being

constructed on the west end of its former footprint to preserve the Greenwich Street corridor for pedestrians and possibly vehicles.

West of the 7 WTC site, the Verizon Building's south side was damaged by the collapse of WTC Tower 1 and its east side was damaged by the subsequent collapse of 7 WTC. Portions of the Verizon Building were recently reopened as the building continues to undergo extensive repairs. To the east, although there is little or no visible damage to the exterior of the massive Federal Office Building/U.S. Post Office, it is undergoing extensive interior cleaning and reconstruction. Vesey Street remains closed between Route 9A and Church Street. A narrow pedestrian walkway runs adjacent to the Federal Office Building/U.S. Post Office (90 Church Street); west of Washington Street the walkway is actually in the bed of Vesey Street. BMCC's Fiterman Hall also sustained extensive damage due to the collapse of 7 WTC and remains closed. These blocks are less populated and therefore noticeably quieter than before September 11, 2001.

The rest of the subarea has seen a number of changes in land use. The Woolworth Building on Broadway between Barclay Street and Park Place is being converted in phases to a mixed-use building to house the New York University (NYU) School of Continuing and Professional Studies (which recently occupied several of the lower floors) and luxury condominiums. Sites 5B and 5C are now used for public and private parking uses and planned for mixed-use residential developments in the future. The area has also seen several residential conversions, the largest of which is 50 Murray Street.

Broadway Corridor. Land use and neighborhood character in the Broadway Corridor are substantially the same today as they were prior to September 11, 2001. The wrought iron fence surrounding St. Paul's grounds has been the location of many informal memorials. The buildings on Church Street immediately east of the WTC site that suffered damage on September 11, 2001, have since reopened with the same uses after undergoing repairs and renovations. Without the WTC buildings across Church Street, these large buildings are now more visible from the north, west, and south.

Although not as busy as before September 11, 2001, the area attracts large numbers of workers and visitors throughout the day and evening traveling to and from work, shopping, or viewing the WTC Site across the street. Traffic along Broadway and Church Street is lighter. More blocks are closed to traffic in the vicinity of the New York Stock Exchange, hindering traffic flow along the east-west streets. While the area is quieter, it is not so different as to indicate any substantial change in neighborhood character.

Greenwich South Corridor. A number of buildings in the Greenwich South Corridor were severely damaged or destroyed as a result of the terrorist attacks. All but one (114 Liberty Street) of the buildings along Liberty Street have been cleaned, renovated, and reoccupied. The reopening of the redesigned FDNY firehouse and the active ground floor businesses along Liberty Street facing the WTC site have brought back activity and with it some sense of normalcy to these blocks which remained inactive for many months, and in some cases years, after September 11, 2001. Immediately south of the WTC site, Liberty Street remains closed to vehicular traffic. Part of Liberty Street is closed off for WTC site reconstruction and part of it is open for pedestrian circulation and access to the Liberty Street bridge across Route 9A to BPC. 90 West Street, planned for residential conversion, is also vacant.

The former office building at 90 Washington Street was converted to residential use, having been partially financed through the Liberty Bond program (see "Changes in the Affected

Environment Since September 11, 2001—Public Policy"). The Downtown Athletic Club has closed since September 11, 2001, and the building remains vacant.

Except for the buildings identified above, land use in the remainder of the Greenwich South Corridor has generally been the same since September 11, 2001. This subarea remains less active than the other subareas surrounding the Project Site, with increased retail and building vacancies and some interior streets closed to traffic.

Battery Park City. The Winter Garden was severely damaged in the aftermath of September 11, 2001, and has since been rebuilt and opened to the public, along with the rest of the shops and offices at the WFC. In the northern part of BPC, the residential buildings at 20 and 22 River Terrace have since opened, and two more residential buildings are under construction nearby. Teardrop Park, a new open space adjacent to 22 River Terrace, is also currently under construction.

The portion of the Route 9A roadway adjacent to the WTC site suffered extensive damage on September 11, 2001, its aftermath, and during the recovery period. Today, a six-lane temporary roadway runs between Liberty and Vesey Streets. One permanent pedestrian bridge across Route 9A at Liberty Street, damaged on September 11, 2001, and two temporary pedestrian bridges at Rector and Vesey Streets help connect BPC to the rest of Lower Manhattan.

The overall neighborhood character remains the same in BPC, with a slightly more active North neighborhood due to the addition of several hundred dwelling units. The buildings of the WFC are more visible from the east but feel more isolated from the Lower Manhattan business core, having been designed to harmonize with the size and design of the Twin Towers. In addition, the ballfields along Route 9A between Warren and Murray Streets were opened for use in the summer of 2003. Teardrop Park between River Terrace and North End Avenue is under construction and expected to be complete in 2004. Across the street from the recently expanded Jewish Museum, the Skyscraper Museum recently opened its doors at the base of the Ritz-Carlton building.

Tribeca. The major change in Tribeca is the continued increase in residential conversions which have appeared throughout the subarea, particularly along Broadway, Hudson Street, and in the northwest corner of the subarea.

Chinatown below Canal Street. Other than a few residential conversions in the western portion of the study area, there is little new development in Chinatown. An increased number of commercial vacancies and dilapidated buildings can be found throughout the subarea with a decrease in street activity since September 11, 2001.

Civic Center. No changes to land use or neighborhood character have occurred in the Civic Center subarea since September 11, 2001.

Brooklyn Bridge to Battery Park. A number of residential conversions and new construction are occurring throughout the subarea. Construction of two new residential buildings is near completion at 2 Gold Street and 10 Liberty Street, both of which are funded in part through the New York Liberty Bond Program (see "Changed to the Affected Environment Since September 11, 2001—Public Policy" below).

At the southern tip of Manhattan, the Whitehall Ferry Terminal is currently undergoing renovations. The Fritz Koenig *Sphere*, a sculpture that originally stood in Tobin Plaza on the WTC site and was damaged on September 11, 2001, stands in Battery Park as an interim memorial.

PUBLIC POLICY

Since September 11, 2001, a number of public policy initiatives have been implemented to assist in the recovery efforts and continued revitalization of Lower Manhattan. These are in addition to policies that continue to be in effect since before the terrorist attacks (see "Pre-September 11, 2001 Baseline Conditions—Public Policy"). The major policies and plans addressing the Project Site and surrounding study area are discussed below.

Lower Manhattan Development Corporation

LMDC was created in November 2001 as a subsidiary of the Empire State Development Corporation (ESDC) to help plan and coordinate the rebuilding and revitalization of Lower Manhattan south of Houston Street so that it will re-emerge as a stronger and more vibrant community. LMDC is charged with assisting New York City to recover from the terrorist attacks on the Twin Towers. Through consultation with its many advisory councils representing a cross-section of affected communities and direct communication with government officials, elected representatives, community organizations, affected individuals, and members of the public, LMDC has gathered information on issues critical to the city's recovery, including transportation and infrastructure, residential and commuter concerns, economic development, education, and tourism and the arts. LMDC has also sponsored several initiatives and studies relating to short-term and long-term solutions to the challenges facing Lower Manhattan neighborhoods in the wake of September 11, 2001. Among these efforts are open space and streetscape improvements and studies of affordable housing, Chinatown traffic and transportation, the Fulton Street corridor, and Greenwich Street south of the WTC site. LMDC receives federal funding through two Community Development Block Grants totaling $2.783 billion from the U.S. Department of Housing and Urban Development (HUD).

New York City's Vision for a 21st Century Lower Manhattan

On December 12, 2002, Mayor Michael Bloomberg released a *Vision for a 21st Century Lower Manhattan* (New York City's *Vision*) with the stated purpose to connect Lower Manhattan to the world around it, build new neighborhoods, and create public places that make Lower Manhattan one of the most appealing places in the world. It was released in conjunction with LMDC's announcement of seven design proposals for the Project Site. The plan describes various recommendations to help revitalize and improve Lower Manhattan as a global center of business by creating new regional transportation links. To attract new investment in the neighborhoods south and east of the Project Site, the city calls for the creation of Fulton Market Square and Greenwich Square. Other goals include improvements to streetscapes, the expansion and creation of public plazas and parks, and the continued revitalization of the waterfront. The *Vision* aims to spark private market reactions from these public investments to increase the number of businesses and residents in Lower Manhattan.

New York Liberty Bond Program

As part of the efforts toward rebuilding and revitalizing New York City in the wake of September 11, 2001, the New York Liberty Bond Program was introduced as a cooperative program between New York Liberty Development Corporation, New York City Industrial Development Agency, New York State Housing Finance Agency, and New York City Housing Development Corporation. These agencies offer tax-exempt financing for the construction and renovation of commercial and residential properties that lie primarily within the Liberty Zone, which is the area of Manhattan south of Canal Street, East Broadway, and Grand Street. The

goal of the program is to create a seven-day-a-week, 24-hour mixed-use, diversified community in Lower Manhattan by repairing and replacing damaged and destroyed commercial space; creating additional multifamily residential and neighborhood retail development; providing modern office space for displaced and decentralized businesses; attracting new residents and employers to New York City; and encouraging environmentally responsible design and construction.

Federal Policies

In recognition of the disastrous impact of the terrorist attacks, President George W. Bush declared Lower Manhattan a national disaster area and $21 billion in aid was approved by the United States Congress for the repair, restoration, and recovery efforts. These funds were allocated to the Federal Emergency Management Agency (FEMA), the Federal Transit Administration (FTA), and HUD for specific objectives and grants to be separately administered by each of the agencies and local project sponsors under Defense Appropriations Act of 2002 (Public Law 107-117), and Supplemental Appropriations Act of 2002 for Further Recovery From and Response to Terrorist Attacks on the United States (Public Law 107-206). The U.S. Small Business Administration (SBA) offered low-interest loans to eligible individuals to repair or replace damaged property and personal belongings not covered by insurance. In addition to emergency response efforts, FEMA's Disaster Housing Program also made funds and services available to individuals whose homes were uninhabitable and also provided cash grants to those who did not qualify for the SBA loans.

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

CONSTRUCTION PERIOD (2006)

FUTURE COMMON TO ALL ALTERNATIVES

Land Use and Neighborhood Character

A number of major projects will be completed during the construction period resulting in increased land use densities throughout the study area. Overall, an additional 1.7 msf of new office space, 1.8 msf of restored office space, 53,000 square feet of additional commercial space, over 700,000 square feet of institutional space, and over 5,400 new residential units are expected for completion by 2006. The major projects are discussed briefly below. A complete list of projects expected to be complete by 2006 in the study area can be found in Appendix A, Table A-1.

While these developments may result in some changes to the character of the area in the immediate vicinity of the development sites, most of the neighborhoods throughout the study area are expected to retain their most prominent characteristics, and overall neighborhood character will be minimally affected. Lower Manhattan will continue to possess a diversity of uses including commercial office, retail, residential, government, cultural, educational, and open space. Residential use will increase as a result of new construction and conversions throughout the study area. Most of the buildings damaged on September 11, 2001 will be repaired and restored to their former use, increasing activity on now underutilized blocks. All new projects are being developed within the boundaries of existing blocks and would not result in the removal of any architecturally distinguished buildings located throughout the study area.

Although additional employees are expected in the area by 2006, the worker population will be substantially less than pre-September 11 densities while the WTC Redevelopment Sites remain largely vacant. Any increase in worker and residential populations is not likely to result in

changes to the character of the neighborhoods beyond the area immediately surrounding the specific developments.

WTC Redevelopment Sites. In 2006, major construction will be in progress at the WTC site on the Memorial, related cultural uses, the retail bases of the four planned office towers, and below-grade concourse levels for retail use and pedestrian connections. The two blocks south of Liberty Street, planned for office and open space uses, will be vacant and possibly used as construction staging areas. The construction of a new St. Nicholas Church is planned and may be underway in 2006.

North of WTC Site. The Verizon Building and the Federal Office Building/U.S. Post Office directly north of the WTC site on Vesey Street will be restored, repaired, renovated, and reopened with the same land uses as existed prior to September 11, 2001. Between these buildings, the new 1.6 msf 7 WTC office tower (and two Con Edison substations) will be completed and occupied. In addition, several residential and mixed-use developments are expected to be built. The largest of these will be on the former WSURA Site 5C at the corner of Chambers Street and Route 9A. NYU's School of Continuing Education and Professional Studies will have expanded its presence at the Woolworth Building (233 Broadway), and 150 new residential units will occupy the upper floors of this landmark building.

Broadway Corridor. No development projects have been identified for completion by 2006 in the Broadway Corridor.

Greenwich South Corridor. Restoration and conversion of 90 West Street will have provided over 400 residences with street-level retail space and accessory parking.

Battery Park City. Most of the vacant parcels remaining in BPC are expected to be complete by 2006. Four primarily residential buildings will have produced almost 1,500 new dwelling units. Some of these buildings will include street-level retail or institutional space to be used by the BPC Parks Conservancy. The planned development at BPC Site 16/17, the large parcel bounded by Murray Street, North End Avenue, Vesey Place, and River Terrace, will contain over 500 housing units, a New York Public Library branch, not-for-profit space, a café, and new public open space. Redevelopment of Pier A between BPC and Battery Park for retail and tourism uses is also expected to be complete before 2006. Lastly, Route 9A south of West Thames Street will have a new esplanade and open space.

Tribeca. Consistent with existing trends, small- to medium-sized buildings throughout Tribeca are expected to continue to be converted from office or industrial to residential use and new residential buildings will be constructed by 2006. These buildings would each contain between 4 and 120 units of various sizes. An expansion is also planned for the New York Law School on Church Street between Leonard and Worth Streets.

Chinatown below Canal Street. No planned or proposed land use development projects in the Chinatown below Canal Street subarea that will be completed by 2006 have been identified.

Civic Center. No development projects have been identified for completion by 2006 in the Civic Center subarea.

Brooklyn Bridge to Battery Park. A number of developments are planned for the Brooklyn Bridge to Battery Park subarea. Several sites will be developed with mixed-use residential buildings, which will include a combination of residential and institutional, office, retail, and/or parking uses. These include the NYU Downtown Hospital parking lot on Gold and Beckman Streets, 15 William Street, also a parking lot, and 2 Gold Street. In total, over 2,700 residential

units will be added to the Brooklyn Bridge to Battery Park subarea by 2009. Millennium High School will have expanded to its full capacity at 75 Broad Street. The reconstructed Whitehall Ferry Terminal will be opened at the southern tip of Manhattan.

Public Policy

The implementation of the projects described above by the 2006 construction year would be consistent with public policies for the area. The city and state policies that support the recovery and growth of Lower Manhattan as both a thriving central business district and an evolving 24-hour community are expected to continue. An increase in residential development through conversions and new construction would be consistent with existing trends for the area. Overall, infrastructure improvements and developments providing new and expanded uses would represent a demonstration of city, state, and federal policy, along with private investment, to rebuild Lower Manhattan.

NO ACTION ALTERNATIVE

In 2006 under the No Action Alternative, the temporary WTC PATH station would continue to operate as it does today with a single entry/exit at Fulton and Church Streets and no change in land use would occur. The temporary WTC PATH station would continue to provide a direct transportation connection between Lower Manhattan and New Jersey and accommodate expected commercial and residential growth throughout the study area (see Chapter 5, "Socioeconomic Conditions"). Construction activity associated with the WTC Memorial and Redevelopment Plan will continue on the remainder of the Project Site independent of this alternative. Land use at the Project Site, including the WFC and Liberty Park Plaza surrounding areas, would not change and no changes to neighborhood character would result.

PREFERRED ALTERNATIVE

Land Use and Neighborhood Character

In 2006, portions of the Preferred Alternative would be operational, with phased completion of other station components expected between 2007 and 2009. Construction on the remainder of the Preferred Alternative would be in progress at the Project Site in conjunction with ongoing construction at the WTC site. No changes in land use would occur. Much of the temporary WTC PATH station would continue to operate as it does today in conjunction with the completed portions of the permanent facility. Throughout the construction period, pedestrian access may be hindered due to sporadic closing, rerouting or narrowing of sidewalks used to access the sole entrance/exit of the temporary WTC PATH station at Fulton and Church Streets. While these construction activities may inconvenience pedestrians, these disruptions would be temporary and no long-term effects to land use or neighborhood character would result.

The construction of the proposed project would have temporary impacts on neighborhood character in the immediate vicinity of the project site. Temporary road closures, trucking activities, noise, and changes in air quality associated with construction activities may temporarily affect the quality of life for employees, residents, and visitors in the vicinity of the Project Site resulting in an adverse impact on neighborhood character in the immediate area. However, such activities are necessary to ensure the long-term vitality of Lower Manhattan and thus are likely to lead to a long-term positive benefit on the community and overall character of the area.

Public Policy

Construction of the Preferred Alternative would be consistent with the goals of PANYNJ, LMDC, and the city's *Vision* to revitalize Lower Manhattan as a competitive, thriving business district. No adverse impacts to public policy would result from the Preferred Alternative in the construction year.

OPENING YEAR (2009)

FUTURE COMMON TO ALL ALTERNATIVES

Land Use and Neighborhood Character

Project Site/WTC Redevelopment Sites. Development through 2009 would result in enormous changes to land use and neighborhood character at the WTC site, independent of the Preferred Alternative. The WTC site will change from a largely vacant site in 2006 to a mixed-use development with a Memorial and museum and office, cultural, retail, and open space uses. To the south, Washington Street will be closed, St. Nicholas Greek Orthodox Church will be reconstructed, and an open space will be created between Route 9A and Greenwich Street. These developments will strengthen and be a key element in the revitalization of Lower Manhattan by introducing a range of active and attractive uses (see Appendix A, Table A-2).

First, the initial development will include the Memorial and the related museum (Memorial Center). The extension of two streets, Greenwich and Fulton, through the WTC site, would recreate north-south and east-west linkages for pedestrians and vehicles that have not existed since before the creation of the WTC. The proposed performing arts center, a major new use for Lower Manhattan, will also face onto this intersection in the heart of the WTC site.

Freedom Tower, at the northwest corner of the WTC site, will also be completed by 2009. At a height of 1,776 feet this structure will be the tallest on the island of Manhattan and restore an element of the skyline lost on September 11, 2001. With 2.6 msf of office space, the tower will begin to replace the Class A office space lost on the WTC site. Its restaurants and observation decks will also be replacements for September 11, 2001 losses.

Retail bases of the three other towers on the WTC site will be complete by 2009 and together with the below-grade retail will provide up to 1 msf for stores. Major portions of this retail space will be at grade and open onto and enliven the sidewalks around and inside the WTC site.

A number of new open spaces will be created totaling approximately 5.6 acres. All of the open spaces, including the Memorial, will be at grade and immediately accessible from the sidewalks. Wedge of Light Plaza and PATH Plaza will be part of the east-west circulation system along with Fulton Street. Liberty Park South will stretch from Greenwich Street to Route 9A.

The potential bus garage for tour buses coming to the Memorial will be located below grade on the WTC site or, possibly, south of Liberty Street.

The Memorial and Memorial Center, along with the observation decks of Freedom Tower and its restaurants, will become major tourist attractions and attract visitors from all over the world to Lower Manhattan. The increase in visitors will benefit area businesses, particularly restaurants and shops well beyond the vicinity of the WTC site throughout the entire land use study area (see Chapter 5, "Socioeconomic Conditions"). Together, the diverse components of the WTC Memorial and Redevelopment Plan will contribute to the creation of a more active and attractive

WTC site. The overall character of the area will be improved from an essentially blighted state into a major destination for workers, tourists, and other visitors.

North of WTC Site. In keeping with the trend of increasing residential use in Lower Manhattan, a large residential project is expected to be complete at 270 Greenwich Street, formerly known as WSURA Site 5B, adding approximately 730 new residential units and 240,000 square feet of major retail uses to the area. This will serve to better connect the blocks to the east of Greenwich Street with BPC to the west by replacing a large, empty parcel with active residential and retail uses. BMCC's Fiterman Hall will be demolished and the site redeveloped for its former educational use.

Broadway Corridor. A major transportation project and several residential developments are expected to be complete in the Broadway Corridor by the 2009 opening year. The FTA in cooperation with MTA and NYCT is planning the Fulton Street Transit Center, scheduled for completion in late 2008/early 2009. The project's goal is to improve access to and from Lower Manhattan. It will consist of the construction and operation of a rehabilitated, reconfigured, enhanced multi-level underground transit hub that will incorporate four subway stations serving 12 subway lines. It will provide underground connections to WTC site developments and the Permanent WTC PATH Terminal, if built, at Dey and Church Streets. In addition, several residential conversions will be complete along Maiden Lane, Fulton, and John Streets.

Battery Park City. Another transportation project expected for completion by 2009 is the rehabilitation of Route 9A between Chambers and West Thames Streets. This section of highway, a portion of which is adjacent to the WTC Site, will either be restored at grade or placed in a short bypass beneath a wide median with an adjacent local roadway. Residential development will also continue in the North and South neighborhoods, adding over 850 residential units to BPC. The North neighborhood developments will include a new indoor community recreation center and additional space for the BPC Parks Conservancy. In the South neighborhood, the planned mixed-use development at 1st Place between Route 9A and Battery Place, will be home to the new Women's Museum. In addition, Site 26 will be developed with a 2.3 million-square foot commercial office tower with ground-floor retail and accessory parking uses.

Tribeca. Segment 3 of the Hudson River Park, which runs from Chambers Street to Houston Street north of the study area, will be complete. Currently in design development, this segment will feature two of the park's longest piers—25 and 26 near North Moore Street in Tribeca—and an "eco-pier" at Canal Street. A number of public use facilities, including a river education center, habitat planting area, boathouse, restaurant, park concessions, playgrounds, volleyball, practice field, boat docking, minigolf, skate park, and other passive and active recreation opportunities, will be operating by 2009. Residential conversions are also expected to continue throughout the subarea.

Brooklyn Bridge to Battery Park. The expanded South Ferry Subway Terminal will be opened at the southern tip of Manhattan. The completely redesigned subway station will accommodate the full length of a typical 10-car subway train (rather than the five cars it accommodates in 2004) and provide new connections to the Staten Island Ferry and to the Whitehall Street subway station. Also planned are several large residential developments through both new construction and conversion. Almost 3000 new dwelling units will be added there by 2009.

More generally, an aggressive street reconstruction program is being undertaken in Lower Manhattan both to relocate and strengthen infrastructure lost during the events of September 11, 2001, and to repair streets damaged by recovery vehicles in the months following. By 2007, the

New York City Department of Design and Construction will have reconstructed nearly all of the city's streets south of Canal Street from river to river.

Public Policy

The implementation of the development projects described above by 2009 will be consistent with public policy in the study area. The city and state policies that support the recovery and growth of Lower Manhattan as both a central business district and an evolving 24-hour community are expected to continue. Infrastructure improvements and developments providing new commercial, residential, and open space uses are being planned by the state and city and will represent a demonstration of city, state, and federal policy to rebuild Lower Manhattan. Several of these projects are federally sponsored, including the Fulton Street Transit Center, Route 9A, South Ferry Terminal, WTC Memorial and Redevelopment Plan, and the numerous commercial and residential developments subsidized through the New York Liberty Bond Program. Together, these projects demonstrate ongoing governmental interest in actively promoting infrastructure improvements and new developments throughout Lower Manhattan.

NO ACTION ALTERNATIVE

Land Use and Neighborhood Character

Under the No Action Alternative, the temporary WTC PATH station would continue to operate on the WTC site. As described above, considerable development is expected at the WTC site and in the surrounding neighborhoods, increasing the demand for PATH service and other modes of public transportation. However, without the increased capacity of the Preferred Alternative, transit service in the area may not meet the demand from other planned land use developments throughout Lower Manhattan. Furthermore, the temporary WTC PATH station is not consistent with the current master plan for the WTC site. In the event that it would need to continue operations through the opening year, components of the WTC master plan would need to be revised to accommodate PATH operations.

Although the absence of the Preferred Alternative may not preclude those developments planned throughout the study area, it may affect the desirability and marketability of Lower Manhattan's residential, office, and retail establishments. As described in Chapter 2, "Project Alternatives," as ridership nears the temporary station's design capacity, PANYNJ would need to implement operational adjustments to safely accommodate passengers, such as reduced service and/or restricted access. PATH service is vital to the movement of employees to and from their offices throughout the study area. In addition, businesses located in Jersey City and Newark depend on PATH to deliver workers from New York City and other points east of the Hudson River. More recently, PATH service has become critical to those businesses that have located facilities in both Lower Manhattan and Jersey City to allow for office expansion while maintaining a close connection between company functions on both sides of the Hudson River. Without full reliance on this critical inter-regional connection, the anticipated developments in Lower Manhattan, which would result in an increase in land use and density, may not come to fruition as quickly or intensely as would be expected under the Preferred Alternative.

Overall neighborhood character would not change substantially as a result of the No Action Alternative. Along with PATH commuters traveling to and from the temporary station, the newly opened Fulton Street Transit Center across Church Street from the Project Site and the existing and planned developments at the WTC site and on the blocks surrounding the Project

Site will generate substantial pedestrian and vehicular traffic throughout the area. The area would remain a bustling business district.

Public Policy

The No Action Alternative would not support the existing city, state, and federal policies that promote the recovery and growth of Lower Manhattan as both a central business district and an evolving 24-hour community. Those policies that support the revitalization of the Lower Manhattan central business district will undoubtedly continue well beyond 2009. The lack of the Preferred Alternative, which restores and improves upon the level of PATH train service that existed prior to September 11, 2001, would hinder the achievement of these policies' goals.

For example, as discussed above, LMDC was created to help plan and coordinate the rebuilding and revitalization of Lower Manhattan so that it will re-emerge as a stronger and more vibrant community. A comprehensive local and regional transportation infrastructure system is a vital part of meeting that objective. One of the stated purposes of New York City's *Vision* is to connect Lower Manhattan to the world around it. The policy includes recommendations to create new regional transportation links to help revitalize and improve Lower Manhattan. The continued operation of the temporary PATH station in 2009 may result in reduced service or restricted access, as discussed in Chapter 2, "Project Alternatives," making it difficult to meet the goals of these policies. Therefore, the No Action Alternative would have an adverse effect on public policy.

PREFERRED ALTERNATIVE

The Preferred Alternative would consist of a track and platform level, a mezzanine/fare-zone level, and a street-level terminal building incorporating sub-grade pedestrian connections to adjacent streets, NYCT subways, and on and off-site developments, including the WFC. The PATH tunnels, tracks, platforms, and mezzanine would be located within the WTC "bathtub" as they were prior to September 11, 2001.

The Preferred Alternative would provide added passenger capacity and pedestrian linkages to surrounding buildings and transit services that the temporary WTC PATH station could not accommodate, and would provide better service to its riders. The opening of the proposed Preferred Alternative would be compatible with the office, retail, cultural, and residential land uses in the surrounding area, benefiting area businesses, office workers, tourists, and residents, and improving the overall character of the Project Site and the surrounding blocks. The Preferred Alternative would be consistent with existing public policy aimed at reviving the Lower Manhattan office market to retain and attract both large corporations and small businesses in conjunction with the developments at the WTC site (see Chapter 5, "Socioeconomic Conditions"). These businesses would have access to the New Jersey workforce as they did before September 11, 2001, while businesses across the Hudson River in Jersey City could depend on a quick and direct commute to Lower Manhattan for the long-term. The new facility would also provide regional connections for potential visitors and patrons who wish to visit the Memorial or any of the new cultural uses developed at the WTC site and surrounding area.

The new facility would not conflict with other land uses or public policies in effect for the area, and would be compatible with the overall character of the neighborhood. No change to land use would result from the Preferred Alternative since it would replace the existing temporary WTC PATH station with the same use in a larger configuration. Overall, the Preferred Alternative would support other public policies that previously existed in Lower Manhattan with the

intention of creating a 24-hours-a-day, seven-days-a-week community. As a result, no adverse impacts to land use or public policy would result.

The new Terminal building, along with the surrounding WTC developments, would benefit overall neighborhood character since the Project Site would change from a blighted construction site to an area with built form and visual identity. PANYNJ owns the WTC site; therefore, the majority of the Terminal's components could be constructed without easements. However, PANYNJ would require easements from NYSDOT and Brookfield Properties for the construction of a Route 9A connection and its proposed entrance adjacent to the Winter Garden. PANYNJ has been coordinating with these property owners for their planning of the Route 9A connection, but the formal execution of these easements would likely not occur until final design of the connection is completed. Since the necessary easements would be negotiated directly with the property owners, their execution is not expected to result in adverse impacts to public policy.

DESIGN YEAR (2025)

FUTURE COMMON TO ALL ALTERNATIVES

Land Use and Neighborhood Character

The 2025 land uses described below assume all projects for the 2009 opening year have been completed. Additional developments, potential or proposed, that have no specific build year have been assumed to occur between 2010 and 2025 and are described below (see Appendix A, Table A-3). In addition, several developments have been identified that could potentially be developed in the future but do not have a defined program associated with a definite site at this time. Specifically, New York City's *Vision* may bring changes that are not yet programmed or approved.

Overall, land use in the study area is expected to follow existing trends toward increasing residential, cultural, and other uses while restoring the office space lost at the WTC and maintaining a strong commercial presence. The distribution of uses is expected to remain much the same as it is today, with commercial development clustered at the WTC site, the blocks immediately north of the WTC site, the Broadway Corridor, and the WFC in BPC, and residential development concentrated in the Greenwich South Corridor, BPC, and North of WTC site subareas. Development of soft sites (i.e., sites not built out to the maximum allowable FAR) may lead to a greater intensity of land uses, with higher-density office and residential uses in the future.

These developments will be in keeping with the traditional character of the Project Site and study area as a densely developed urban setting. The area surrounding the Project Site will continue to function as a bustling business district. In addition, it will contain a greater mix of uses with better transportation connections that will help to create a livelier environment, not only during the workday but during evening hours and on weekends. All of these uses will be compatible with those land uses that exist throughout the study area and will help to make Lower Manhattan a more attractive and welcoming place to live, work, and visit.

WTC Redevelopment Sites. By 2025, it is assumed that the developments for the WTC Memorial and Redevelopment Plan will be complete. In addition to the Memorial, Memorial Center, cultural facilities, retail uses, and open space, full development will bring the total office space to 10 msf and add a hotel with conference facilities. This office space will be in towers above the bases and below-grade areas with up to 1 msf of retail space. There will be five large, modern office towers ranging in area from 1.6 msf to 2.6 msf, each with between approximately

56 and 70 stories of office space. The hotel will provide up to approximately 800 rooms and up to 150,000 square feet of conference facilities. The additional office space, hotel, and their associated populations will support and benefit the retail and cultural uses developed in the initial phase of the plan.

North of WTC Site. No specific development projects have been identified for completion between 2010 and 2025 in the North of WTC Site subarea. It is likely that residential conversions will continue.

Broadway Corridor. New York City's *Vision* includes residential construction in the Broadway Corridor. Other potential future development in the Broadway Corridor includes three complete residential conversions and the conversion of the upper floors of a large office building on Broad Street to residential use.

Greenwich South Corridor. New York City's *Vision* will create a public open space, Greenwich Square, over the Brooklyn Battery Tunnel ramps with the intention of stimulating new residential development or residential conversions in the area.

Battery Park City. All of BPC is expected to be developed by 2009. No additional developments have been identified for completion between 2010 and 2025.

Remaining Subareas. Commercial and residential development is expected to continue in the remainder of the study area between 2010 and 2025 as a continuation of trends foreseen for 2009. Residential projects, both conversions and new construction, are proposed throughout the study area with the majority concentrated in the Tribeca and Brooklyn Bridge to Battery Park subareas.

In addition, two major transportation projects are also anticipated for completion before 2025. Under consideration for decades, the FTA recently issued a Record of Decision for the Second Avenue Subway. The project is proposed to provide much needed transit access to residents, workers, and visitors on the east side to reduce excess crowding on the Lexington Avenue subway and to improve overall mobility. The project consists of a new, two-track, 8.5-mile subway extending from Lexington Avenue at 125th Street in Harlem to Water Street at Hanover Square in the Brooklyn Bridge to Battery Park subarea.

Finally, the city proposes to provide direct, one-seat airport access to JFK and Newark International Airports. The project involves extending the JFK AirTrain system from the airport through a new tunnel to Lower Manhattan and by extending the PATH train from Newark's Penn Station to Newark Liberty Airport. The new tunnel between downtown and JFK would also connect the area to any Long Island Rail Road (LIRR) train at Jamaica Station. It is anticipated that the Lower Manhattan Terminal would be in the vicinity of the proposed Fulton Street Transit Center and the Permanent WTC PATH Terminal.

Public Policy

The developments described above that are expected to be completed between 2010 and 2025 will continue to be consistent with public policy for the area. These developments demonstrate the city and state's long-term interests in both rebuilding and promoting the continuous success of Lower Manhattan.

NO ACTION ALTERNATIVE

Land Use and Neighborhood Character

The existing temporary WTC PATH station was constructed for use on an interim basis, and therefore would be retired from service and no longer in operation long before the 2025 design year. At the same time, developments planned as part of the WTC Memorial Redevelopment Plan will be complete and fully occupied, as described above. Without the Preferred Alternative, the above- and below-grade portions of the Project Site may be incorporated into other WTC site developments. Land use on those portions of the Project Site located at Liberty Park Plaza and the WFC are not expected to change by 2025 under this alternative.

At this time it is unknown what, if anything, would occupy the former footprints of the temporary WTC PATH station after it ceases operations. In any event, the No Action Alternative would leave Lower Manhattan without an important regional transportation connection at a time when such a use will be critical. The WTC PATH Terminal served over 67,000 commuters a day prior to September 11, 2001, the events of which left the PATH system without a large portion of its capacity to serve commuters throughout the New York and New Jersey region. With a substantial increase in commercial office, retail, cultural, and residential uses expected by 2025 at the WTC Redevelopment Sites and in the surrounding neighborhoods, New Jersey residents will require convenient access to the Lower Manhattan business district, and without PATH no direct connection would exist. As discussed in Chapter 8A, "PATH," over 167,000 weekday passengers who would have used the Permanent WTC PATH Terminal in year 2025 would be required to divert to alternate modes of transportation to access Lower Manhattan.

The No Action Alternative would reduce the desirability and marketability of those independent developments planned for the study area, including those at the WTC site itself. Existing Lower Manhattan businesses may relocate to other areas of Manhattan or leave New York City altogether. As a result, the revitalization of Lower Manhattan may not be as robust as would otherwise be expected and any benefits to neighborhood character would not be realized.

Public Policy

The No Action Alternative would be inconsistent with public policies in place for Lower Manhattan, as discussed above for the 2009 opening year. No PATH train service would exist between New Jersey and the central business district. At the same time, the WTC Redevelopment Sites and the surrounding blocks would be fully developed and occupied. A major part of the infrastructure needed to support the Lower Manhattan office and retail markets would not exist. The lack of an important regional transportation connection—one that existed prior to September 11, 2001—would frustrate existing public policies that aim to better integrate and serve the Lower Manhattan business district with New Jersey, Long Island, Midtown Manhattan, and other boroughs, as well as nearby neighborhoods. Therefore, this alternative would result in an adverse impact on public policy.

PREFERRED ALTERNATIVE

Land Use and Neighborhood Character

In 2025, the Preferred Alternative would contribute to the creation of a more active Project Site and would benefit land use and neighborhood character. The Preferred Alternative would be compatible with and supportive of surrounding land uses. By 2025 PATH service into Lower Manhattan would be even more important than it is today, or is expected to be in 2009, due to

the increased intensity of land uses that are expected at the WTC Redevelopment Sites and throughout the land use study area, as described above. PATH service would again become an integral part of the Lower Manhattan central business district, as it was prior to September 11, 2001.

The Preferred Alternative would bring workers and visitors who, by purchasing goods and services, would support the existing businesses in the surrounding study areas, enlivening the surrounding study area. This alternative would support the increased office development and new cultural uses in the area. The influx of commuters associated with this alternative would benefit area businesses, particularly restaurants and shops, well beyond the Project Site, improving neighborhood character. Therefore, the Preferred Alternative would have beneficial effects on the surrounding areas, and no adverse impacts to land use or neighborhood character would result from this alternative. All other uses and their effects on land use and neighborhood character would be similar to conditions described in 2009.

Public Policy

This alternative is part of a major public policy initiative led by PANYNJ in cooperation with other federal, state, and city agencies to restore the Project Site as a functioning part of Lower Manhattan and maintain its place as a transportation hub for the Downtown area. The Preferred Alternative would be consistent with plans and efforts to maintain Lower Manhattan as a prosperous business district and to make the area more attractive to retain existing and attract new businesses in the long term. The project would be consistent with and help to meet the goals of public policies for Lower Manhattan, and no adverse impacts to public policy would result.

E. MITIGATION

During the construction period, activities associated with the Preferred Alternative may result in adverse impacts related to socioeconomic conditions, traffic, air quality, and noise and vibrations (see Chapter 5, "Socioeconomic Conditions," Chapter 8, "Transportation," Chapter 9, "Air Quality," and Chapter 10, "Noise and Vibration"). As a result, these activities would have an adverse effect on neighborhood character in the immediate vicinity of the Project Site. The mitigation measures proposed for each of the technical areas discussed above would also minimize the adverse effects to neighborhood character during the construction period.

Since the project would not have long-term (opening or design year) adverse impacts, as described above, mitigation would not be required once the Terminal is operational. ✷

A. INTRODUCTION

This chapter assesses the potential impacts of the Preferred Alternative on the socioeconomic characteristics of Lower Manhattan, including population and housing profiles, commercial office and retail activity, and employment trends.

B. METHODOLOGY

FRAMEWORK OF ANALYSES

A socioeconomic analysis describes whether and how a proposed action will impact the population, housing stock, or economic activities in a geographic area. Projects are examined for their potential to influence these socioeconomic characteristics (either directly or indirectly), and any anticipated changes are evaluated based on both their magnitude and character.

Typically, a proposed action should be examined for its potential to affect change through direct residential or business displacement, indirect residential or business displacement, and effects on a particular industry. The Preferred Alternative would not directly or indirectly displace businesses or residents nor would it adversely affect a specific industry. Thus, this assessment focuses on the Preferred Alternative's potential for social and economic impacts and benefits to Lower Manhattan.

As described in Chapter 2, "Project Alternatives" and Chapter 15, "Cumulative Effects," PANYNJ has coordinated with the other sponsors of the Lower Manhattan Recovery Efforts (Lower Manhattan Development Corporation, Metropolitan Transportation Authority, and New York State Department of Transportation) to develop a consistent approach to the evaluation of potential environmental effects for their respective projects. The methodology described below for the social and economic conditions analysis follows this guidance, and the development of baseline and future conditions has been closely coordinated between the project sponsors.

BASELINE CONDITIONS

As described in Chapter 2, "Project Alternatives," the Preferred Alternative is analyzed under current, and pre-September 11, 2001 conditions. This chapter presents two baselines. The first summarizes population, housing, employment, and commercial real estate characteristics as they existed prior to September 11, 2001, and the second presents those characteristics for the study areas today.

Following the baseline discussion is an assessment of future conditions in the study areas for three different analysis years: 2006 (which falls within the construction period), 2009 (the opening year) and 2025 (the design year). For each year, future socioeconomic conditions are described for the Future Common to All Alternatives as well as the No Action and Preferred Alternative.

STUDY AREA DEFINITIONS

The socioeconomic study area is Lower Manhattan, south of Canal Street. Study area subareas vary by subject matter, depending on the level of detail appropriate for the analyses and the types of data available. Subareas for each section of the socioeconomic analysis are defined below.

POPULATION AND HOUSING

There are nine Population and Housing subareas, including the World Trade Center (WTC) site. Those subareas immediately surrounding the WTC site include: North of WTC Site, Battery Park City, Greenwich South Corridor, and Broadway Corridor. Those on the periphery include: Tribeca, Civic Center, Chinatown, and Brooklyn Bridge to Battery Park (see Figure 5-1).

COMMERCIAL OFFICE MARKET

The study area for the Commercial Office Market analysis has been divided into five submarkets, which conform to data collected by the real estate services firm Cushman & Wakefield. These submarkets are mapped in Figure 5-2, and are further described below:

- City Hall: Bound by the Brooklyn Bridge, Park Row, Vesey Street, Chambers Street, Hudson River, Canal Street, and the East River.
- World Financial: Bound by Albany Street, Hudson River, Chambers Street, Church Street, Vesey Street, Broadway, Liberty Street, and Greenwich Street.
- Insurance: Bound by Pine Street, William Street, Liberty Street, Broadway, Park Row, and the Brooklyn Bridge.
- Financial West: Bound by Battery Park, Hudson River, Albany Street, Greenwich Street, Liberty Street, and Broadway.
- Financial East: Bound by Battery Park, Broadway, Liberty Street, William Street, Pine Street, and the East River.

In order to contextualize the Lower Manhattan office market data, it is compared to data describing other Manhattan submarkets, including Midtown South and Midtown. The three major Manhattan submarkets are mapped in Figure 5-3.

COMMERCIAL RETAIL MARKET

The Commercial Retail Market has not been divided into submarkets. However, because the Preferred Alternative could have an effect on retail establishments located on blocks immediately surrounding the proposed entrances to the Terminal, a smaller study area has been defined for the Retail analysis. This "Immediate Study Area" consists of the blocks immediately surrounding the WTC site, along with buildings lining the east side of Broadway from Pine Street to Ann Street (see Figure 5-2). More specifically, the Immediate Study Area includes:

- The World Financial Center on the west side of the WTC site;
- Blocks between Route 9A and Broadway, Vesey, and Barclay Streets;
- Blocks between Vesey and Thames Streets, Church Street, and Broadway;

- Blocks on the south side of Liberty Street, from West Street to Church Street.

EMPLOYMENT

The Employment study area, which includes all of Lower Manhattan south of Canal Street, has not been divided into submarkets.

DATA SOURCES

POPULATION AND HOUSING

The assessment of population and housing trends in the Primary and Secondary Study Areas is based on data from the 1990 and 2000 Census. The information was grouped into three content areas:

- Population characteristics, including total number, race, and median age;
- Housing characteristics, including number of units, vacancy and tenure (owner versus renter occupied), median contract rent, and median home value; and
- Household characteristics, including number of households, average size and income, and percent below poverty.

The data have been organized by subarea. However, because the subareas were defined according to land use patterns and commonly used neighborhood definitions, boundaries do not always conform to Census geography (Tract, Block Group, or Block). Where Census units overlap subarea boundaries, a judgment was made regarding the extents of the Census unit to include in the subarea based on land uses in the area and the potential for the characteristic being examined to cross the Census unit in question.

There is some discrepancy between the precision with which the 1990 and 2000 data conforms to subarea boundaries. Because much of the 1990 data is reported only by Tract and Block Group levels (not at the level of the Census Block, the smallest geographic unit), the 1990 data is not as precise as the 2000 data for some demographic and housing characteristics. However, every effort was made to ensure a consistent comparison between these data.

The pre-September 11, 2001 condition is based primarily on 2000 Census data. Because the Census is dicennial, it is impossible to obtain an accurate 2003 demographic and housing profile of the study areas. Thus, the current condition is based largely on 2000 data updated with information and survey data compiled from various agencies and organizations involved in the redevelopment of Lower Manhattan, such as the Alliance for Downtown New York (Downtown Alliance) and the Lower Manhattan Development Corporation (LMDC). Much of the 2003 housing and population data is based on an assessment of units built in the study areas between 2000 and 2003 and corresponding population estimates based on 2000 average household sizes by subarea. The list of recent housing development was compiled from a variety of sources including real estate firms, newspaper articles, Community Board 1, Downtown Alliance, and the New York City Department of City Planning (NYCDCP).

OFFICE

Office market trends and current conditions for Lower Manhattan and Manhattan, as a whole, are presented using data from Cushman & Wakefield. Four main indicators were used to depict market conditions: total inventory, average rent, vacancies, and absorption. Wherever possible, these indicators were reported separately by class of office space. Office class definitions are as follows:*

- *Class A*: Most prestigious buildings competing for premier office users with above average rents for the area. Buildings have high quality standard finishes, state-of-the-art systems, exceptional accessibility and suggest a definitive market presence.
- *Class B*: Buildings competing for a wide range of users with average rents for the area. Building finishes are fair to good for the area and systems are adequate, but the buildings do not compete with Class A at the same price.
- *Class C*: Buildings competing for tenants requiring functional space at below average rents for the area.

The post-September 11, 2001 condition is portrayed using data from the second quarter of 2003, and the pre-September 11, 2001 condition reflects data from the second quarter of 2001.

RETAIL

Data on the Manhattan and Lower Manhattan Retail markets was obtained primarily from the Retail Report series published by the Real Estate Board of New York and the Fulton Corridor study commissioned by LMDC.** In addition, a field survey was conducted in September 2003 to develop a comprehensive list of businesses in the "Immediate Study Area."

EMPLOYMENT

Employment data for Manhattan and New York City are from the New York State Department of Labor (NYSDOL). The discussion of employment trends is based on data from 1990, 1995, 2000, and 2002. Second quarter 2000 data were used for the pre-September 11, 2001 conditions and second quarter 2002 data (the most recent data available) were used for the post-September 11, 2001 conditions.

Employment data for Lower Manhattan is based on employment estimates from the New York Metropolitan Transportation Council (NYMTC) supplemented with industry-specific data from NYSDOL. It is difficult to accurately quantify employment in Lower Manhattan using NYSDOL data because it is available only by zip code, and zip code 10013 is bisected by Canal Street, the northern boundary of the Study Area. Although the NYMTC data in its original form is county-based, it has been adjusted to the Census Tract level and used for several transportation projects in Manhattan with the endorsement of a variety of City agencies. Thus, the NYMTC data was used to quantify employment in Lower Manhattan. (It should be noted

---

* Cushman and Wakefield. *Market Beat Series*. Individual reports from Cushman and Wakefield are referenced in text and tables presented later in this document.

** LMDC. *Fulton Corridor: Creating a Vision for Enhanced Retail+Arts+Cultural Activities in Lower Manhattan*, June 12, 2003

that overall, the NYMTC-based private sector employment estimate is approximately 6 percent higher than the NYSDOL-based estimate.)

To estimate employment by industry (or Standard Industrial Code—SIC) for Lower Manhattan, the NYSDOL employment distribution was applied to the NYMTC employment estimates for 2000 and 2002. For example: if, according to the NYSDOL, 35 percent of Lower Manhattan employment in 2000 was in the Services sector, then this distribution was applied to the NYMTC.

The NYMTC employment figures include both public and private sector employment, with subtotals by sector. While private sector employment is based on 2000 data, the public sector employment estimate is based on 1990 data—the most recent year for which data is available. However, government employment for New York City, as a whole, changed only modestly from 1990 to 2000 (decreasing by about 5 percent in magnitude).

ENVIRONMENTAL JUSTICE

Executive Order 12898, "Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations," requires that every federal agency identify and address disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority and low-income populations.

As discussed in the existing conditions portion of this chapter, the primary study area population is over 75 percent white, with a median household income that is over twice the median for New York City and a poverty level that is well below the citywide average. The secondary study area includes two subareas with populations that are over 50 percent minority: Chinatown (approximately 86 percent minority) and Civic Center (approximately 65 percent minority). These communities also have a relatively high proportion of persons living in poverty—37.5 percent in Civic Center and 33.4 percent in Chinatown, as compared to 20.8 percent in New York City. However, these communities are geographically further removed from the proposed project and would not suffer disproportionately high and adverse impacts from the proposed project. Therefore, a more detailed environmental justice analysis was deemed unnecessary. Nevertheless, as more fully discussed in Chapter 18, "Agency Coordination, Process, and Public Participation," FTA and PANYNJ reached out to low-income and minority populations in an effort to include them as part of the project's public participation program.

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

PRE-SEPTEMBER 11, 2001 BASELINE CONDITIONS

POPULATION AND HOUSING

Population

Table 5-1 presents characteristics of the Lower Manhattan population in 1990 and 2000. In 2000, there were approximately 58,620 people living in Lower Manhattan. About 44 percent of the total population lived in Chinatown. Approximately 48 percent of the study area population was White, almost 40 percent was Asian, and only 6.4 percent was Black. This contrasts with the racial profile of Manhattan as a whole, which was approximately 54 percent White,

Table 5-1
Pre-September 11, 2001 Population Characteristics in Lower Manhattan (1990 and 2000)

Primary Study Area	Total Population					Median Age[4]
	Total	Race and Ethnicity (Percent)[1,2]

Lower Manhattan Total	**58,618**	**47.8**	**6.4**	**39.4**	**6.4**	**37.2**
Manhattan	1,537,195	54.4	17.4	9.4	18.9	35.7
New York City	8,008,278	44.7	26.6	9.8	18.9	34.2

Notes:

1 White, Black, Asian, and Other population may also be Hispanic.

2 Race categories were reported differently in the 1990 and 2000 Census. In order to draw comparisons, the 2000 Census categories of "Asian Alone" and "Native Hawaiian and Other Pacific Islander Alone" were combined into "Asian" and the categories of "American Indian and Alaska Native Alone," "Some Other race alone," and "Two or more races" were combined into "Other." For 1990 data, the "Other" category combines the categories of "American Indian, Eskimo, or Aleut" and "Other race."

3 Because the 1990 census data is not reported by block, and neighborhood boundaries do not conform with block group boundaries, it was not possible to calculate the exact population or population by race within neighborhood boundaries. The population was derived by calculating the percent of population in each block group living within the neighborhood boundaries in year 2000 and applying that same percent to the 1990 block group population figures. The race percentage is based on racial breakdown of entire block groups into which the neighborhood falls.

4 Median age is the weighted average of the median ages for each census tract, block group, or block falling within the subarea. Median age can not be calculated for 1990.

Source: U.S. Department of Commerce, Bureau of the Census, 2000 Census, Summary File 1 and 1990, Summary File 1.

17 percent Black, and 9 percent Asian. As illustrated in Table 5-1, the uncharacteristically high Asian representation in Lower Manhattan is due to the high number of people living in Chinatown, which is nearly 75 percent Asian.

Of all subareas in Lower Manhattan, Brooklyn Bridge to Battery Park experienced the greatest net increase in population between 1990 and 2000 (growing by approximately 4,365 people), and Greenwich South Corridor had the greatest percentage increase (growing from 122 to 1,142 residents). For all subareas, the Asian population constituted a larger percent of total population in 2000 than it did in 1990. At the same time, the White and Black populations in most subareas shrunk as a percent of total population.

The average median age in 2000 was eldest in Chinatown and Tribeca (almost 40 in both subareas) and youngest in the Broadway Corridor and Greenwich South Corridor subareas.

Housing

As illustrated in Table 5-2, there were approximately 27,143 housing units in Lower Manhattan in 2000. Overall, about 20 percent were owner-occupied and 80 percent were renter-occupied, which mirrors the overall Manhattan housing market. The study area's vacancy rate was only moderately higher than in Manhattan (9.4 as compared to 7.5) but the rate varied substantially across subareas. At 17.9 percent, Battery Park City had the highest vacancy rate, which may be attributable to the substantial number of newly constructed but not yet occupied units that were built late in the 1990s.

The 2000 median home value in Lower Manhattan was $411,040, approximately 14 percent higher than the median for Manhattan, and 86 percent higher than the median for New York City. The area's median contract rent (or weighted average of median contract rents for all subareas) of $1,130 per month was over 50 percent higher than the median rent for Manhattan. It is worth nothing that the median home value and median contract rent for Chinatown were substantially lower than in many other Lower Manhattan subareas; which deflates the overall averages for the study area.

Between 1990 and 2000, the housing stock in Lower Manhattan increased much faster than it did in Manhattan or New York City. While the number of units in the study area increased by 30 percent, the Manhattan housing market grew by only 1.6 percent and the New York City market by 6.9 percent. The majority of growth occurred in the Battery Park City, Tribeca, and Brooklyn Bridge to Battery Park subareas, having a total of 4,480 new units between 1990 and 2000.

While the number of units increased from 1990 to 2000, the overall ratio of owner- to renter-occupied housing units remained almost constant and the vacancy rate increased by only 1.7 percent. Median contract rent increased by approximately $434 between 1990 and 2000.

Households and Income

There were approximately 24,615 households in Lower Manhattan in 2000 with an average size of 2.2 people. The vast majority of households (22,464 in number) were located in four subareas: Chinatown, Brooklyn Bridge to Battery Park, Battery Park City, and Tribeca. The study area's median household income of approximately $65,090 was about 38 percent higher than for Manhattan and 70 percent higher than for New York City. The poverty rate, however, was roughly equal to that of Manhattan—primarily due to the high poverty rate in Chinatown (33.4 percent). The North of WTC site subarea had the highest median income and lowest poverty rate in the study area. Table 5-3 presents income characteristics for Lower Manhattan.

Table 5-2
Pre-September 11, 2001 Housing Characteristics in Lower Manhattan, (1990 and 2000)

Primary Study Area	Total Housing Units	Housing Vacancy (Percent)	Housing Tenure (Percent)		Median Contract Rent[1, 3]	Median House Value[1, 2, 3]
			Owner	Renter

Manhattan	785,127	8.8	17.9	82.1	$630	N/A
New York City	2,992,169	5.8	26.6	71.4	$590	N/A
2000						
North of WTC Site	761	8.3	58.9	41.1	$1,510	$548,133
Broadway Corridor	841	11.8	16.7	83.3	$1,220	$478,080
Greenwich South Corridor	739	15.8	0.8	99.2	$2,000	$187,500
Battery Park City	5,382	17.9	17.7	82.3	$1,873	$318,600
Tribeca	4,786	8.3	32.7	67.3	$1,254	$782,455
Civic Center	91	2.2	1.1	98.9	$170	N/A
Chinatown	9,465	5.4	11.0	89.0	$449	$203,094
Brooklyn Bridge to Battery Park	5,078	8.0	25.0	75.0	$1,413	$548,058
Lower Manhattan Total	**27,143**	**9.4**	**20.5**	**79.5**	**$1,130**	**$411,040**
Manhattan	798,144	7.5	20.1	79.9	$740	$361,100
New York City	3,200,912	5.6	30.2	69.8	$646	$221,200

Notes:

1 Values were calculated by taking the weighted average of median number of rooms, median contract rent, and median house value of all the census block groups in a given study area. Because this data is available only at the block group level and block group boundaries do not always align with subarea boundaries, the medians are not exact. Block groups were included or excluded depending on how much of the block group lay within the subarea and whether the housing in the block group was consistent in character with housing in other parts of the subarea.

2 The 1990 median home value is not reported because the 1990 value was based on "specified owner-occupied housing units" only, while the 2000 median was based on all owner-occupied housing units. The two data sets are not comparable.

3 All 1990 values were converted to 2000 constant dollars using the U.S. Department of Labor's Consumer Price Index for the "New York-Northern New Jersey-Long Island" area.

Chinatown	8,955	2.7	$23,867	33.4
Brooklyn Bridge to Battery Park	4,670	1.7	$57,525	10.4
Lower Manhattan Total	**24,615**	**2.2**	**$65,090**	**19.8**
Manhattan	738,644	2.0	$47,030	19.4
New York City	3,021,588	2.6	$38,293	20.8

Notes:

1 The median income represents a weighted average of the median incomes of all the census blocks or block groups in the subarea.

2 The U.S. Census Bureau uses a set of money income thresholds that vary by family size and composition to detect who is poor. If the total income for a family or unrelated individual falls below the relevant poverty threshold, then the family or unrelated individual is classified as being "below the poverty level."

3 All 1990 values were converted to 2000 constant dollars using the US Department of Labor's Consumer Price Index for the "New York-Northern New Jersey-Long Island" area.

Source: U.S. Department of Commerce Bureau of the Census, 1990 and 2000 Census, Summary Files 1 and 3.

Table 5-4
Pre-September 11, 2001 Manhattan Office Market Characteristics (Year-End 2000)

Submarket	Total Inventory (sq. ft.)	Total Average Rent	Class A Average Rent	Total Vacancy Rate
Midtown	224,320,504	$54.65	$67.11	3.6 percent
Midtown South	60,614,279	$46.70	$50.23	3.6 percent
Lower Manhattan	107,512,756	$43.29	$52.37	3.6 percent
Total	392,447,539	$50.12	$64.51	3.7 percent

Source: Cushman & Wakefield, second quarter 2003.

Between 1990 and 2000, the study area gained a total of 5,573 households, an increase of 29.3 percent. Median household income increased by 26 percent, from $51,580 to $65,090. The most substantial increase in income occurred in the Greenwich South Corridor, the subarea, which also experienced the most dramatic growth in the number of households.

COMMERCIAL OFFICE MARKET

At year-end 2000, Manhattan's office inventory totaled 392,447,539 square feet. Approximately 57 percent was located in Midtown, 27 percent in Lower Manhattan, and 15 percent in Midtown South. As indicated in Table 5-4, vacancy rates were low, absorption was high, and total average rents ranged from $43.29 per square foot (psf) to $54.65 psf.

During the second quarter of 2001, Lower Manhattan contained approximately 107.8 million square feet (msf) of office space. Over half was considered Class A, which was generally distributed between two submarkets: World Financial and Financial East. Class B space was concentrated in the Financial East area, and the City Hall submarket contained 40 percent of all Class C space.

The WTC site itself contained over 10 msf of office space in five buildings. The Twin Towers, (One and Two World Trade Center) were 110 stories each and contained approximately 4.7 msf of Class A office space per building.

Table 5-5 shows inventory and average rents for each of the submarkets in Lower Manhattan in the months immediately preceding September 11, 2001. As shown, the average rent for Lower Manhattan office space in 2001 was $41.17 psf. Class A space rented at approximately $47.50 psf, Class B at $37.70 psf, and Class C at $37.08 psf.

Table 5-5

Source: Cushman & Wakefield, second quarter 2001.

The office vacancy rate in Lower Manhattan was fairly low immediately preceding the September 11, 2001 attacks. As indicated in Table 5-6, the vacancy rate was 6.5 percent, with vacancies in all submarkets except for Financial West ranging between 3.4 and 7.3 percent. The vacancy rate for the Financial West subarea was 21.5 percent.

COMMERCIAL RETAIL MARKET

At the end of March 2001, Manhattan had a total of 10.6 million square feet (msf) of available retail space (or 1,850 stores) with an average rent of $98 psf. By the end of September 2001, Manhattan had 11.3 msf of available retail space (1,744 stores), with an average asking rent of $84 psf. Though some of this drop can be attributed to the attacks of September 11, 2001, much of the decrease was underway in the months prior to September 11, 2001, as regional and national economies began to slow.

In Lower Manhattan, a total of 1.6 msf of retail space was available as of March 2001, and the average asking rent was $60 psf. Like the overall Manhattan retail market, the Lower Manhattan market was showing signs of weakness prior to September 11, 2001, evidenced by the drop in average asking rents from $67 psf in September 2000 to $60 psf in March 2001.

EMPLOYMENT

New York City and Manhattan

Approximately 3.1 million people were employed in New York City's private sector in 2000, and almost two thirds (1.9 million) worked in Manhattan. In both Manhattan and New York City as a whole, the greatest concentration of employment was in the Services industry. The largest proportion of all Services employment was in the Business Services and Health Services subsectors. In Manhattan, 31 percent of all Services employment was in Business Services, and 14 percent was in Health Services. In New York City, 24 percent was in Business Services and 23 percent in Health Services. Public Sector employment in New York City totaled approximately 549,100 in 2000, comprising about 15 percent of all employment in the City. Of those employees, approximately 66,700 worked for the federal government, 42,100 for the state, and 440,300 for local government agencies.

In Manhattan, 418,236 employees (22 percent of the private labor force) worked in the Finance, Insurance and Real Estate (FIRE) sector, and another 18 percent worked in retail or wholesale

trade. By comparison, New York City's workers were less concentrated in the FIRE industries (16 percent of private sector employees) and somewhat more concentrated in the trade industries (20 percent of private sector employees).

Between 1990 and 2000, private sector employment in Manhattan grew by about 3.4 percent, or 64,400 workers. The largest absolute growth occurred in the Services sector, which gained 161,525 employees, growing by 22 percent. Retail Trade also experienced substantial growth, adding about 34.8 thousand employees to its 1990 base of 198,273. Employment in Wholesale Trade declined by 29,000 workers. Employment in the FIRE industries decreased by over 7 percent, from 451,400 to 418,200 employees.

Lower Manhattan

In 2000, there were approximately 426,008 employees in Lower Manhattan. As shown in Table 5-7, approximately 40 percent were working in the FIRE sector and another 36 percent worked in the Services sector. Within the Services sector, 36 percent worked in "Business Services," and within FIRE, 65 percent worked in the "Security and commodity brokers, dealers, exchanges, and services" subsector as a whole.

Table 5-7
Pre-September 11, 2001 Lower Manhattan Employment (2000)

Industry	Number	Percent
Private Sector Employment	331,841	100.0 %
Agriculture, Forestry, Fishing, and Hunting	164	0.0 %
Mining	2	0.0 %
Construction Industries	4,486	1.4 %
Manufacturing	16,826	5.1 %
Transportation, Communication, and Utilities	13,385	4.0 %
Wholesale Trade	9,633	2.9 %
Retail Trade	34,990	10.5 %
Financial, Insurance, Real Estate	130,370	39.3 %
Services Industries	120,887	36.4 %
Unclassified Establishments	1,097	0.3 %
Public Sector Employment	94,168	22.1 %
Total Employment	426,009	100.0 %

Notes:

1. Due to NYSDOL data suppression practices, the sum of employment by industry did not exactly match the total private sector employment figure. Employment that was unaccounted for in the industry breakdown was added to "Unclassified Establishments."
2. For private sector employment industry subcategories, "Percent" represents percent of private sector employment, not total employment. For main public and private Sector headings, "Percent" represents the relative contribution of private and public employment to total employment.

Sources: Number of firms was obtained from NYSDOL 2002 employment data. Employment was estimated using NYSDOL data to generate an employment estimate that is consistent with NYMTC employment estimates.

Compared to Manhattan, Lower Manhattan had a high concentration of FIRE sector employment. About 38 percent of all FIRE employment in Manhattan and 32 percent of all New York City FIRE employment was located within Lower Manhattan, making it more than twice

as concentrated in the FIRE industries as Manhattan and about three times more concentrated than the City as a whole.

CHANGES IN THE AFFECTED ENVIRONMENT SINCE SEPTEMBER 11, 2001

POPULATION AND HOUSING

Population

The Lower Manhattan population has gone through some dramatic changes since the 2000 Census. Following September 11, 2001, the population in Lower Manhattan (particularly in those subareas surrounding the WTC site) dropped, as people were forced to leave their homes during the beginning phases of the WTC site cleanup. While some of the area's residents returned when conditions permitted, others chose to relocate elsewhere, driving vacancy rates upward and keeping the population below its pre-September 11, 2001 level. However, residential grant programs were successful in convincing many to remain, return, or relocate to Lower Manhattan. Thus, vacancy rates have decreased and population has grown.

According to the Downtown Alliance, residential vacancy rates in Lower Manhattan have now returned to their pre-September 11, 2001 levels.* Assuming a) an overall vacancy rate of 5 percent in residential buildings that existed in 2000 as well as those built between 2000 and 2003 (see Housing sections below for more detail) and b) that the average housing size remains the same as in 2000, the population in Lower Manhattan has grown by approximately 10,077 (17 percent) since the 2000 Census, resulting in a total of approximately 68,695. The majority of this growth occurred in the Greenwich South Corridor and Brooklyn Bridge to Battery Park subareas, where populations increased by approximately 2,730 and 3,400 people respectively.

Information on the current racial composition of subarea populations is not available. Judging from the modest changes that occurred between 1990 and 2000, it is assumed that the racial composition has not changed markedly since the 2000 Census.

Housing

Lower Manhattan included approximately 27,140 housing units in 2000. Since then, the area has gained approximately 5,774 housing units, growing by 21 percent. Approximately 36 percent of the new units were built in the Brooklyn Bridge to Battery Park subarea; another 1,690 units were added to the Greenwich South Corridor subarea, and 835 units to Battery Park City. With the exception of Battery Park City, which has new construction, many new units in the Study Area are in buildings converted from commercial use. Most new units are upscale, with rents equal to or higher than the median for their respective subareas.

Households and Income

Current information on household and income characteristics is not available. However, judging from rental rates and general size of apartments constructed between 2000 and 2003, it is assumed that median income and average household size in Lower Manhattan have not changed greatly since 2000.

* Downtown Alliance. *The Downtown Report.* Winter 2003.

COMMERCIAL OFFICE MARKET

Manhattan Office Market

Since the end of 2000, the Manhattan office market has lost approximately 3.2 msf of space, and average rental rates have decreased by approximately 18 percent. Vacancy rates have increased from 3.7 to 12.5 percent.

According to second quarter 2003 data, the Manhattan office market currently contains approximately 390 million square feet (msf) of office space. Of that space, 58 percent (approximately 227 msf) is considered Class A, and 27 percent (about 104 msf) is considered Class B. The vast majority (75 percent) of Class A space is located in Midtown. Class B and C space is more evenly dispersed across the submarkets, with Midtown containing the largest portion of Class B space, and Midtown South the greatest amount of Class C.

Table 5-8 presents the inventory and average rent by class of space for the Manhattan submarkets. The total average rent for Manhattan office space in 2003 is approximately $41 psf. Class A space commands an average rent of $48.50 psf and Class C, $26.75 psf. Class A rents are much higher in Midtown than in Downtown or Midtown South—about $10 psf higher than Downtown and $17 psf higher than Midtown South. The average rental rate for Downtown as a whole ($36.36 psf) is notably lower than the average rent for all of Manhattan ($41.12 psf).

Table 5-8
Post September 11, 2001 Midtown Office Inventory and Rents (2003)

Submarket	Class A		Class B		Class C		Total	
	Inventory (sq.ft.)	Total Avg. Rent	Inventory (sq.ft.)	Total Avg. Rent	Inventory (sq.ft.)	Total Avg. Rent	Inventory (sq.ft.)	Total Avg. Rent
Midtown	171,977,201	$51.50	41,780,038	$35.94	17,442,468	$24.49	231,199,707	$46.56
Midtown South	9,943,982	$34.37	30,241,234	$32.82	24,993,692	$27.37	65,178,908	$31.09

Source: Cushman & Wakefield, second quarter 2003.

As indicated in Table 5-9, the vacancy rate for office space in Manhattan is currently 12.5 percent. Of the three submarkets, Midtown South has the highest vacancy rate (14.5 percent). Overall, Class B space has a slightly higher vacancy rate (13.1 percent) than Classes A (12.4 percent) or C (12.2 percent). The vacancy rate for Class A buildings is higher Downtown than in other submarkets.

Source: Cushman & Wakefield. Downtown New York Office Market Data, second quarter 2003.

Lower Manhattan Office Market

The Lower Manhattan office market has changed in many ways since 2001 (see Table 5-10). The total inventory in 2003 is about 14 percent less than it was in 2001—a difference of about 15 msf. The most dramatic change occurred in Class A inventory, which decreased by approximately 23 percent. The decrease in Class A space occurred primarily from the loss of the WTC and surrounding buildings. A small fraction of that loss was countered by an increase of 0.75 msf of Class A space in Financial West between 2001 and 2003.

Table 5-10
Post September 11, 2001 Lower Manhattan Office Inventory and Rents (2003)

Submarket	Class A		Class B		Class C		Total	
	Inventory (sq.ft.)	Total Avg. Rent	Inventory (sq.ft.)	Total Avg. Rent	Inventory (sq.ft.)	Total Avg. Rent	Inventory (sq.ft.)	Total Avg. Rent
World Financial	10,202,802	$44.13	2,447,114	$29.27	1,396,150	$32.00	14,046,066	$40.58
City Hall	5,181,465	$40.99	3,492,656	$29.23	5,904,094	$30.60	14,578,215	$33.02
Insurance	5,202,929	$33.25	7,170,386	$27.90	4,393,706	$26.95	16,767,021	$29.85
Financial West	1,438,315	$34.51	3,433,528	$32.56	1,569,242	$29.24	6,441,085	$33.72

Total	45,375,476	$41.57	32,249,155	$30.58	15,266,018	$28.49	92,890,649	$36.36

Source: Cushman & Wakefield. Downtown New York Office Market Data, second quarter 2003.

Average rents in Lower Manhattan have decreased dramatically since 2000. Overall, rent dropped by 13.2 percent from $41.17 psf to $36.36 psf. Class C rents dropped by the greatest percentage (23 percent) and Class A the least (13 percent). Among Downtown submarkets, rents in the Insurance area experienced the most drastic decrease (dropping by 24 percent).

Data from the second quarter of 2003 indicates that Lower Manhattan now has a total inventory of approximately 93 msf of office space. Of that space, 49 percent is considered Class A. Over 50 percent of Class A space is located in the Financial East submarket. Class B space is also concentrated in Financial East, while the City Hall and Insurance submarkets contain the majority (a combined 67 percent) of Class C space.

As illustrated in Table 5-11, vacancy rates in Lower Manhattan vary across submarkets and class of space. The World Financial and Financial West submarkets have the highest vacancy rates (24.7 percent and 22.9 percent respectively). Vacancies are most common in Class A space at approximately 14.3 percent as compared to 11.5 percent of Class B space and 10.2 percent of Class C space.

Table 5-11

COMMERCIAL RETAIL MARKET

According to the New York City Department of Finance, Manhattan has a total of 108.6 msf of retail space. Approximately 41 percent (44.4 msf) is located in Midtown South, 31 percent (33.9 msf) in Midtown, and 6.5 percent Downtown.

The average asking rent varies considerably among submarkets. Average asking rents are highest in the East Side and are lowest in Upper Manhattan. The average asking rent dropped dramatically between Spring 2001 and Spring 2003, from $98 psf to $88 psf. The amount of available retail space increased only modestly over that same period from 10.6 msf to 11.3 msf. The amount of available space was 14.5 msf in Spring 2003.

Lower Manhattan contains approximately 7.1 msf of retail space and comprises approximately 6.5 percent of the retail space in Manhattan. According to the Real Estate Board of New York (REBNY), almost 2.3 msf of Lower Manhattan's retail space was available in Spring 2003. The average asking price is $58 psf, which is markedly lower than the $88 psf average asking rent for Manhattan as a whole.

September 11, 2001 had considerable negative impacts on the Lower Manhattan retail market. Approximately 325,000 sf of retail space was destroyed at the World Trade Center, and many retail establishments in the area were closed for several months following the attacks. Retailers reported a dramatic drop in sales after the attacks, resulting both from a decline in office and tourist populations and from the temporary decline in the residential population. The vacancy rate below Chambers Street increased from 10 percent in August 2001 to 17 percent in May 2002, and the average asking rent decreased from $60 psf to $58 psf.

Retail activity improved as people and businesses returned to Lower Manhattan. Major Downtown stores such as Century 21 and J&R Computer World have reopened, and new stores such as Ann Taylor Loft, Nine West, and Crunch Gym have appeared in Lower Manhattan. However, the average asking rent is still $2 psf lower than in Spring 2001 and $9 psf less than in Fall 2000.

The retail market in Lower Manhattan includes a broad range of services, but is heavily concentrated in the food industries. A survey conducted by Wall Street Rising in August 2002 indicated that approximately one third of the retail establishments south of Chambers Street were food-oriented, with 20 percent falling into the Deli/Fast Food/Take-Out category and 11 percent in the Restaurant category. Roughly another third of the retail base was in the GAFO (general merchandise, apparel and accessories, furniture and home furnishings, and other comparison goods) category, with approximately 11 percent of all retail stores selling apparel and accessories. Neighborhood services such as nail and hair salons, cleaners/tailors, and shoe repair shops constituted another 15 to 20 percent of the retail south of Chambers. *

Immediate Study Area Retail Market

The Immediate Study Area includes the blocks immediately surrounding the Project Site. The retail mix in the Immediate Study Area reflects the composition of the retail market in Lower Manhattan as a whole with a heavy concentration of food-oriented and GAFO businesses. (Refer to Figure 5-4, later in this chapter.)

---

* Wall Street Rising. *Downtown Retail Attraction Program*. March 2003. Section 3.

The World Financial Center currently contains a total of 33 retail establishments on two floors. Twelve are eating or drinking places, 10 are GAFO stores, 9 sell convenience goods, and 2 offer neighborhood services. As of March 2003, there were 19 available stores in the World Financial Center, ranging from 574 to 13,620 square feet.

The remainder of the study area contains 70 retail establishments. Most are street level. A few have street-level entrances with second floor space, and others are located slightly below street level. Of the 70 stores, 24 are GAFO, 21 are eating or drinking establishments, 14 sell convenience goods (with 4 focusing on food items), and 7 provide neighborhood services. At the time of this field inspection, the area included four vacant storefronts, one on the northeast corner of Church and Vesey Streets, two along Liberty between Greenwich and Trinity Streets, and one on the northeast corner of Broadway and Maiden Lane.

EMPLOYMENT

New York City and Manhattan

Between 2000 and 2002, employment in every private sector industry except for "Unclassified" decreased. The Services industry lost the greatest number of employees (about 51,000) while the Wholesale Trade and Manufacturing industries lost the greatest percent of employees (10 and 16 percent, respectively).

According to second quarter 2002 employment data from the NYSDOL, there were approximately 2.9 million individuals working in the private sector in New York City. Over 60 percent were employed in Manhattan. (See Table 5-12.) Service industries—which include a wide variety of jobs in hotel, educational services, legal services, automotive repair, and health services—employed the largest number of people and the greatest percentage of the total private sector workforce in both New York City and Manhattan. In Manhattan, employment in service industries was approximately 850,140, or 47 percent of the overall private sector market. In New York City, 46 percent of the private sector workforce was employed in Services. After Services, the industry employing the greatest number of Manhattan workers was FIRE. These workers comprised over 21 percent of Manhattan's private sector workforce. In New York City as a whole, however, FIRE constituted only 16 percent of total employment. Outside Manhattan, Trade, particularly Retail Trade, was the second-highest employer, comprising approximately 20 percent of the private sector workforce.

Public sector employment represented 16 percent of all employment in New York City in 2002. Of the 553,887 public sector employees, approximately 60,700 worked for the federal government, 42,600 for the State, and 450,600 for local government.

Lower Manhattan Employment

The September 11, 2001 attacks and the economic downturn that followed had a dramatic impact on employment in Lower Manhattan. The attack destroyed seven buildings and damaged approximately 23 others.* According to TenantWise.com, the buildings that were destroyed and damaged contained 608 tenants (450 tenants in destroyed buildings and 158 tenants in damaged buildings). Approximately 137,920 jobs were initially displaced.

Source: New York State Department of Labor, second quarter 2002.

As of March 2002, 55.3 percent of displaced jobs had returned to Lower Manhattan. Another 27 percent had relocated to Midtown, 11 percent to New Jersey, and 5 percent to other locations. TenantWise.com reports that as of September 2003, only 91 of the 186 large corporate tenants (those occupying over 10,000 sf of office space) forced to relocate following the attacks had returned to Lower Manhattan.

In light of these displacement and relocation estimates, it is not surprising that Lower Manhattan lost approximately 71,256 employees, representing 17 percent of its 2000 workforce. The greatest loss was in the FIRE sector, which decreased by approximately 25 percent. Retail was also hit hard, losing approximately 11 percent of its 2000 base.

In 2002, there were 354,753 private and public sector jobs in Lower Manhattan. As shown in Table 5-13, almost 40 percent of the private sector employees worked in service industries and another 35 percent worked in the FIRE sector. Within the FIRE industries, over 60 percent were in the "Security and commodity brokers, dealers, exchanges, and services" subsector and another 14 percent were at banks, in the "Depository institutions" subsector. The greatest percentage of employees in the Services Industry (31 percent) were in "Business Services."

Table 5-13
Post-September 11, 2001 Lower Manhattan Employment (2002)

Industry	Number	Percent
Private Sector Employment	276,336	77.9 %

2. For private sector employment industry subcategories, "Percent" represents percent of private sector employment, not total employment. For main public and private sector headings, "Percent" represents the relative contribution of private and public employment to total employment.

Sources: Number of firms was obtained from NYSDOL 2002 employment data. Employment was estimated using NYSDOL data to generate an employment estimate that is consistent with NYMTC employment estimates.

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

CONSTRUCTION PERIOD (2006)

FUTURE COMMON TO ALL ALTERNATIVES

By 2006, Lower Manhattan will gain an estimated 6,023 housing units, an increase of 18 percent over its 2000 base, and an estimated 10,856 residents (see Table 5-14). Accounting for these additional housing units and those known to have been constructed between 2000 and 2003, Lower Manhattan will have 38,581 housing units and approximately 78,929 residents by 2006.

Lower Manhattan will gain approximately 3.55 msf of office space. When added to the 92.9 msf of space in Lower Manhattan in 2003, the total space will be approximately 96.45 msf by 2006. Retail area will increase by 110,400 sf between 2003 and 2006, resulting in a total of approximately 7.21 msf of space. The projected retail employment, office employment, and other employment (from hotel and institutional uses) are added to the 2002 base of 354,753, it yields an estimated 2006 figure of approximately 369,966 jobs.

Table 5-14
Projected Housing, Population, and Employment in Lower Manhattan in the Construction Period (2006)

Estimate	Residential (DU)	Office (sf)	Retail (sf)	Population	
				Residential	Employee
Post-September 11, 2001	32,558	92,900,000	7,100,000	68,073	354,753
Incremental Growth	6,023	3,550,800	110,400	10,856	15,213
Total 2006	38,581	96,450,800	7,210,400	78,929	369,966

Notes: Population estimates were generated by multiplying the number of housing units (DU) by the 2000 average household size for each subarea. Employment estimates were generated by applying standard employee/square foot ratios to anticipated development.

In addition to the jobs that would be created by new development in Lower Manhattan, the major, federally-sponsored recovery efforts that are independent of the Preferred Alternative are anticipated to result in significant numbers of construction jobs in 2006. As will be described below for the Preferred Alternative, these workers will provide for substantial increases in spending and tax revenues within Lower Manhattan.

NO ACTION ALTERNATIVE

Under the No Action Alternative, the temporary WTC PATH station would continue to operate as it does today with a single entry/exit at the intersection of Fulton and Church Streets. There would be construction activity on the WTC site associated with the WTC Memorial and Redevelopment Plan. Although access to the temporary WTC PATH station would be retained at all times, certain routes to and from the Fulton Street entrance may be restricted to allow for construction staging and other activities. However, since there would be no active uses on the WTC site during the construction period, these restrictions would not have a direct economic effect.

As will be described in Chapter 15, "Cumulative Effects," the simultaneous construction of transportation and development projects in Lower Manhattan may have impacts to local residents and businesses. Temporary road closures, trucking activities, and construction noise may temporarily affect the quality of life for employees and residents in the vicinity of the WTC site.

PREFERRED ALTERNATIVE

Construction of the Preferred Alternative would not displace residents or businesses since no such uses are currently located on the WTC site. The plans for the Preferred Alternative have been closely coordinated into the WTC Memorial and Redevelopment Plan; thus, its construction would also not preclude future cultural, office, and retail projects on the WTC site. Off-site construction is limited to portions of Route 9A and the Winter Garden at the World Financial Center. In their planning for these off-site activities, PANYNJ has ensured that no commercial or residential spaces would be directly displaced.

The majority of the Preferred Alternative's construction would occur within the WTC site. Where off-site construction would be required, PANYNJ would prepare a Maintenance and Protection of Traffic (MPT) plan to ensure that residents, employees, and visitors to Lower Manhattan can access destinations throughout the study area (see Chapter 8, "Transportation").

Environmental Performance Commitments (EPCs) would be undertaken to communicate with local businesses regarding construction activities and to provide for signage and advertising to promote businesses directly impacted by construction activities. Thus, the Preferred Alternative would not eliminate access to existing residential, business, or retail establishments during the construction period.

Access to the temporary WTC PATH station would be retained throughout the construction period. However, as certain components are completed, additional entrances and exits would be provided. As described below, the anticipated changes in pedestrian flows associated with the Preferred Alternative would not result in adverse impacts to businesses in the Immediate Study Area.

The construction of the Preferred Alternative would be coordinated with the overall redevelopment of the WTC site. Although additional construction equipment and labor would be required for the Terminal's construction, the types of activities and their potential effects on local populations would occur with or without the Preferred Alternative since the WTC Memorial and Redevelopment Plan would occur independently. However, to minimize any potential adverse effects associated with the construction of the Preferred Alternative, PANYNJ would implement EPCs as described in Chapter 2, "Project Alternatives," and later in this chapter under Section E, "Mitigation."

As described in Chapter 2, "Project Alternatives," the Draft Environmental Impact Statement evaluated a Permanent WTC PATH Terminal both with and without a sub-grade connection beneath Church Street to Liberty Plaza. The alternative with the concourse was projected to cost $81 million more than the alternative without the concourse. However, since publication of the DEIS, PANYNJ has advanced the design of the Preferred Alternative, which does not include this sub-grade concourse, and has determined that certain components would be more costly than originally estimated. Thus, the Preferred Alternative would have a higher construction cost ($2.138 billion) than the "Terminal with Liberty Plaza Connection Alternative" presented in the DEIS.

The construction of the Preferred Alternative would generate new construction jobs and resultant economic benefits for Lower Manhattan. The principal model used to estimate the effect of constructing the Terminal on the city's economy is the Regional Input-Output Modeling System (RIMS II), developed by the U.S. Department of Commerce, Bureau of Economic Analysis. The model contains data for New York City on 490 economic sectors, showing how each sector affects every other sector as a result of a change in the quantity of its product or service. A similar RIMS II model for New York State, also developed by the U.S. Department of Commerce, has been used to trace the effects on the State economy. The models have been adjusted to reflect the most recent changes in the New York metropolitan area price level. Using these models and the specific characteristics of the project, the total effect has been projected for New York City and State.

The development of this alternative would be undertaken by the investment of funds into the area. Based on preliminary estimates, the capital investment for construction of the Preferred Alternative is estimated to equal about $2.138 billion. This amount includes site preparation and hard costs (actual construction), and design, legal, and related costs. The total estimated amount of $2.138 billion reflects the cost of physical improvements to the site, and therefore excludes other values (such as financing) that are not directly a part of the expenditures for construction.

The $2.138 billion represents the direct expenditures during the construction period. As a result of the direct expenditures, the direct employment is estimated at about 10,533 person-years of employment. (A person-year is the equivalent of one employee working full-time for a year.) In addition to direct employment, total employment resulting from construction expenditures would include jobs in business establishments providing goods and services to the contractors and resulting indirect and generated employment. Based on the model's economic multipliers for New York City industrial sectors, the Preferred Alternative would generate an additional 5,779 person-years of employment within New York City, bringing the total direct and generated jobs from the construction to 16,312 person-years (see Table 5-15). In the larger New York State economy, the model estimates that this alternative would generate 9,432 person-years of indirect employment, bringing the total direct and generated jobs from construction to 19,965 person-years of employment.

The direct wages and salaries during the construction period are estimated at $661.50 million (see Table 5-15). Total direct and generated wages and salaries resulting in New York City from construction are estimated at $988.94 million. In the broader New York State economy, total direct and generated wages and salaries from construction of the Preferred Alternative are estimated at $1.18 billion ($1,184.88 million).

Based on the RIMS II model for New York City and State, the total economic activity, including indirect expenditures (those generated by the direct expenditures), that would result from construction is estimated at $3.97 billion in New York State, of which $3.10 billion would occur in New York City (see Table 5-15).

The construction activity would have associated with it tax revenues for New York City, the Metropolitan Transportation Authority (MTA), and New York State. Based on aggregate data on economic activity and tax receipts for the New York City and State economies, it is estimated that, in total, the construction of the Terminal would generate approximately $146 million in tax revenues for New York City, MTA, and New York State. Of these tax revenues, the largest portion would come from personal income taxes, corporate and business taxes, sales tax on indirect expenditures, and related taxes on direct and induced economic activity. New York State would receive about $96.81 million from construction of the Preferred Alternative. The MTA (which collects a 0.25 percent sales tax and tax surcharges on business and utilities taxes within the city and the MTA 12-county region) would receive about $2.96 million. New York City would receive about $46.5 million.

OPENING YEAR (2009)

FUTURE COMMON TO ALL ALTERNATIVES

Table 5-16 summarizes the development and population growth anticipated in Lower Manhattan by 2009. The combined new construction of dwelling units, offices, and retail between 2003 and 2009 will increase both the residential and employee populations of Lower Manhattan. In total, the area is expected to gain 10,060 dwelling units, 6.15 msf of office space, and 1.38 msf of retail space between 2003 and 2009. This will result in a total of 42,618 dwelling units, 99.05 msf of office space, and 8.48 msf of retail space.

In total, the area's residential population will increase by 28 percent between 2003 and 2009 from 68,073 to 86,893. The combined development of offices, retail, hotels, and institutional uses in Lower Manhattan is expected to increase its employment by nearly 9 percent over the same six year period from 354,753 to 386,081.

Table 5-15
Employment and Fiscal Benefits from Construction of the Preferred Alternative

	Portion in New York City	Total New York City And State
Employment (Person-years)*		
Direct (Construction)	10,533	10,533
Indirect (Secondary and Induced)	5,779	9,432
Total	16,312	19,965
Wages and Salaries (Millions)		
Direct (Construction)	$661.50	$661.50
Indirect (Secondary and Induced)	$327.44	$523.38
Total	$988.94	$1,184.88
Total Economic Output or Demand** (Millions)		
Direct (Construction)	$2,138.0	$2,138.0
Indirect (Secondary and Induced)	$957.7	$1,832.6
Total	$3,095.7	$3,970.6
	Fiscal	
Tax Revenues*** (Constant 2003 dollars)		
New York City Taxes	$46,485,500	
MTA Taxes	$2,963,000	
New York State Taxes	$96,809,500	
Total	$146,258,000	

Notes:
* A person-year is the equivalent of one person working full-time for a year.
** The economic output or total effect on the local economy derived from the direct construction spending.
*** Includes personal income taxes, corporate and business taxes, sales tax on indirect expenditures, and numerous other taxes on construction and secondary expenditures.

Table 5-16
Projected Housing, Population, and Employment in Lower Manhattan in the Opening Year (2009)

Estimate	Residential (DU)	Office (sf)	Retail (sf)	Population	
				Residential	Employee
Post-September 11, 2001	32,558	92,900,000	7,100,000	68,073	354,753
Incremental Growth	10,060	6,150,800	1,380,400	18,820	31,328
Total 2009	42,618	99,050,800	8,480,400	86,893	386,081

Notes: Population estimates were generated by multiplying the number of housing units by the 2000 average household size for each subarea. Employment estimates were generated by applying standard employee/square foot ratios to anticipated development.

NO ACTION ALTERNATIVE

Under the No Action Alternative, the temporary WTC PATH station would continue to operate in the opening year. As described in Chapter 8, Section A, "PATH," PANYNJ anticipates that the temporary station can fully accommodate the anticipated increase in workers and residents in Lower Manhattan in the 2009 opening year.

PREFERRED ALTERNATIVE

Upon its completion, the Preferred Alternative would have positive impacts to the residential and business populations of Lower Manhattan. As described in Chapter 8, Section A "PATH," the Preferred Alternative would serve approximately 67,000 passengers on an average weekday. The transportation link between New Jersey and Lower Manhattan would improve the marketability of office space in the study area and would support the growing residential population of Lower Manhattan.

The Preferred Alternative would include a small retail component (less than 5,000 sf), but there would be no residential or office uses within the project limits. Thus, the Preferred Alternative would not alter the 2009 projected employment or population characteristics described above.

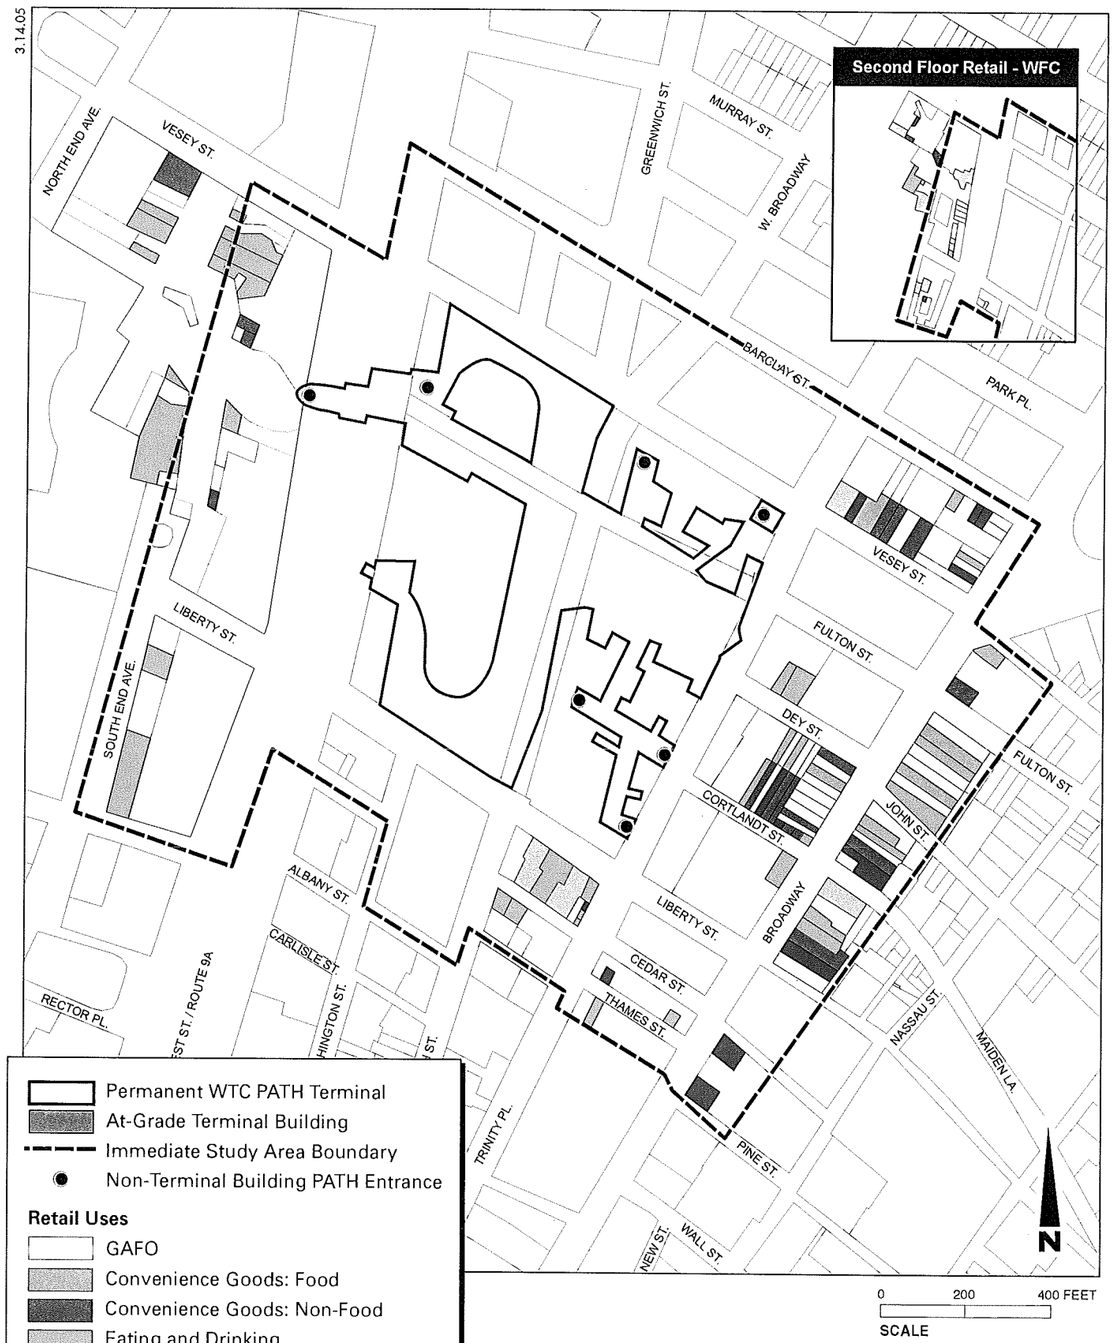
Although the Preferred Alternative may increase the desirability of Lower Manhattan's residential market, its effects would not be powerful enough to alter the existing demographic or housing profile nor would it alter existing trends. Over the past two decades, Lower Manhattan has experienced residential growth that is unmatched by most parts of the city. Between 1990 and 2000, the housing stock in the subareas immediately surrounding the WTC site increased by 44 percent as compared to 1.6 and 6.9 percent for Manhattan and the city as a whole, respectively. As described under the Future Common to All Alternatives, this trend is expected to continue. Based on current and anticipated statistics, the area would not contain a substantial population that would be vulnerable to indirect displacement. Thus, any upward pressures in real estate resulting from the development of the Preferred Alternative would not result in adverse impacts from the displacement of local residents.

The Preferred Alternative would not directly displace business or residents, would not introduce major new economic activities, and would not replace property that has a blighting effect on existing commercial development. Therefore, the Preferred Alternative would not result in indirect business displacement. If anything, it would have a positive indirect effect to the Lower Manhattan office market by providing improved access to existing and proposed developments.

Prior to September 11, 2001, approximately 140,000 people used the WTC PATH Terminal on a daily basis, generating a reliable stream of foot traffic for retail establishments in the Immediate Study Area. Figure 5-4 shows existing retail uses in the Immediate Study Area by category along with the proposed access points to the Terminal, which would be generally positioned in the same location as before September 11, 2001 with two exceptions: 1) a sub-grade connection to the Winter Garden at the World Financial Center, and 2) connection to Fulton Street Transit Center's Dey Street Concourse.

The proposed Winter Garden entrance would replace the second-level pedestrian bridge that existed before September 11, 2001. This entrance may alter pedestrian patterns within the World Financial Center as compared to the pre-September 11, 2001 condition, but any changes would be modest and would not substantially impact existing businesses in the World Financial Center. The new Dey Street concourse, which is being constructed independent of the Preferred Alternative, would allow a direct, sub-grade connection between subways located along

3.14.05



PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure 5-4
Retail Uses

Broadway, Fulton, Nassau, and William Streets and the WTC site and Permanent WTC PATH Terminal. This new transfer may attract some pedestrians from street-level; however, the businesses located en route would not be substantially impacted by these diversions. Thus, the Preferred Alternative would not have adverse indirect effects to retail establishments in the Immediate Study Area.

The Preferred Alternative would not directly alter the employment characteristics of the study area since it would not include an office component or substantial commercial development. The small amount of retail that is proposed would be comparable to that which existed prior to September 11, 2001. This retail would employ up to 15 people, representing a small addition to the more than 382,800 jobs that would be located south of Canal Street in 2009. Any potential impacts to employment would be positive since the Preferred Alternative would improve access to jobs for both residents of New Jersey and Lower Manhattan.

DESIGN YEAR (2025)

FUTURE COMMON TO ALL ALTERNATIVES

Table 5-17 summarizes the development and population growth anticipated in Lower Manhattan by 2025. In total from 2003 to 2025, Lower Manhattan is expected to gain 12,217 new housing units, nearly 15 msf of new and reoccupied office space, and nearly 1.5 msf of new and reoccupied retail space. In total the area will house 90,775 residents and will employ 421,873 in offices, retail, hotels, and cultural and institutional facilities.

Table 5-17
Projected Housing, Population, and Employment in Lower Manhattan in the Design Year (2025)

Estimate	Residential (DU)	Office (sf)	Retail (sf)	Population	
				Residential	Employee
Post-September 11, 2001	32,558	92,900,000	7,100,000	68,073	354,753
Incremental Growth	12,217	14,912,850	1,470,700	22,702	67,120
Total 2025	44,775	107,812,850	8,570,700	90,775	421,873
Pre-September 11, 2001	27,143	107,512,756	7,450,000	58,618	426,000

Notes: Population estimates were generated by multiplying the number of housing units by the 2000 average household size for each subarea. Employment estimates were generated by applying standard employee/square foot ratios to anticipated development.

The residential population of Lower Manhattan is expected to increase substantially as compared to before September 11, 2001. By 2025, the area will house 90,775 residents, representing a 79 percent increase over the 25 year period. Although the area will realize a net gain in retail and office spaces, the total employment in 2025 is expected to be quite similar to pre-September 11, 2001 conditions. By 2025, employment will be within 1 percent of its pre-September 11, 2001 levels. The estimates presented in Table 5-18 indicate that while the office and retail markets in Lower Manhattan will have recovered from the terrorist attacks by 2025, the area's drastic increase in its residential population exemplify Lower Manhattan's changing focus from a 9 to 5 business center to a 24-hour neighborhood.

NO ACTION ALTERNATIVE

By 2025, the temporary WTC PATH station would be retired from service since it would have reached the end of its useful service life. Absent the Preferred Alternative, PATH operations would be suspended between New Jersey and the WTC site. As described in Chapter 1, "Purpose and Need," Chapter 8, "Transportation," and previously in this chapter, the aftermath of September 11, 2001 had devastating affects to the economy of Lower Manhattan. Access to the area was limited by the loss of PATH service between New Jersey and the WTC. It is anticipated that if this connection was again lost, growth in population and employment would not be as robust as currently projected.

This assertion is supported by surveys and studies involving businesses currently located in Lower Manhattan. For example, the "Executive Survey" performed by the Downtown Alliance in April 2003 revealed that transportation access to Lower Manhattan is an issue of high importance to senior executives at leading Downtown companies. The survey indicates that for many leading businesses, the decision to remain in or relocate to Lower Manhattan is heavily based on the convenience and ease with which their employees and clients can reach their facilities. Thus, the absence of a WTC PATH Terminal under the No Action Alternative may contribute to an out-migration of some existing firms, and discourage other firms from locating in Lower Manhattan.

As discussed in Chapter 8, Section B ("Vehicular Traffic and Parking"), vehicular traffic during AM and PM peak hours is expected to increase by more than 1,200 trips under the No Action Alternative. This addition would represent a considerable increase in congestion and could have adverse impacts at key locations, especially near the major portals such as the Holland Tunnel and along the Route 9A corridor. These new vehicle trips could negatively impact businesses in Lower Manhattan, making it more difficult for trucks to deliver goods, for employees to reach their workplaces, and for customers to reach retailers.

Thus, the combination of increased vehicle traffic and decreased transportation access under the No Action Alternative could have a serious adverse impact on the long-term vitality of the Lower Manhattan economy.

PREFERRED ALTERNATIVE

As previously described, the Preferred Alternative would not include a residential or office component. The proposed retail component would be comparable to what existed prior to September 11, 2001 and would not have an effect on employment in Lower Manhattan. Thus, the Preferred Alternative would not alter the development, population, or employment characteristics described above for the Future Common to All Alternatives.

Furthermore, the Preferred Alternative would have no adverse direct or indirect effects on residents or businesses in the design year. While ridership would increase between 2009 and 2025, this change would have positive impacts to businesses within the Immediate Study Area. It is expected that any effects of the Preferred Alternative would be beneficial as compared to existing and No Action conditions and that there would be no adverse impacts to social or economic conditions in Lower Manhattan.

E. MITIGATION

During the construction period, activities associated with the Permanent WTC PATH Terminal may restrict access or limit the visibility of certain businesses in the immediate vicinity of the Project Site. To minimize adverse effects to these businesses, PANYNJ would undertake EPCs that both promote the business climate and Lower Manhattan and retain access to businesses, to the extent possible. These EPCs and the proposed implementation plans are described in Table 5-18.

Table 5-18
Environmental Performance Commitments

Proposed Commitment	Implementation Plan
Coordinate with LMDC, Downtown Alliance or other entities to minimize residential and retail impacts as required through: a) relocation assistance, as applicable, to persons to businesses physically displaced by the project; and b) focus on essential business and amenities to remain in Lower Manhattan.	This would be implemented as part of the Maintenance and Protection of Traffic (MPT) Plan and the coordinated Transportation Management Plan (TMP) among the Lower Manhattan Project sponsors. All businesses in the affected area would be mapped, in conjunction with the MPT and construction staging plans, to determine conflicts on business access. The MPT Plan and TMP would then identify solutions to these conflicts.
Add appropriate signage for affected businesses and amenities.	This would be implemented as part of the project's MPT Plan.

As described in Chapter 2, "Project Alternatives," PANYNJ has and continues to coordinate with the sponsors of the other Lower Manhattan recovery efforts to further refine the EPCs and protocols for their implementation. This includes public outreach planning to inform businesses and residents of issues during the construction period. This plan will employ a variety of methods to communicate with the public during construction of the Preferred Alternative including targeted outreach to residents and businesses adjacent to the Project Site as well as a wider campaign for Lower Manhattan through community and interest groups, media, and other public relations tools. Refer to Chapter 18, "Agency Coordination, Process, and Public Participation," for a description of outreach activities to date.

Since the Preferred Alternative would not have long-term (opening or design year) adverse impacts, as described above, mitigation would not be required once the Terminal is operational. ✱

A. INTRODUCTION

Lower Manhattan is home to many of New York City's most important historic resources and some of its finest architecture. It is the oldest and one of the most culturally rich sections of the city. Thus, numerous buildings, street fixtures and other structures have been identified as historically significant. This chapter assesses the potential impacts of the Preferred Alternative on archaeological and historic resources.

B. METHODOLOGY

In general, potential effects on archaeological or historic resources can include both direct physical effects (e.g., demolition, alteration, or damage from construction on nearby sites) and indirect, contextual effects, such as the isolation of a property from its surrounding environment, or the introduction of visual, audible, or atmospheric elements that are out of character with a property or that alter its setting. To assess the potential effect of a project, an Area of Potential Effect (APE) is defined and an inventory of archaeological and historic resources located in the APE is compiled.

This section describes the delineation of the APE, the inventory, and the assessment of potential effects of the Preferred Alternative.

REGULATORY CONTEXT

The National Environmental Policy Act (NEPA) requires the consideration of potential impacts to historic resources. In addition, potential effects on historic resources are considered in conformance with Section 106 of the National Historic Preservation Act of 1966 (NHPA), Section 4(f) of the United States Department of Transportation Act of 1966 (Section 4[f]), and the New York State Historic Preservation Act of 1980 (SHPA). In addition, the New York City Landmarks Law and potential impacts to New York City Landmarks (NYCLs) and New York City Historic Districts (NYCHDs) have been considered.

NATIONAL HISTORIC PRESERVATION ACT (SECTION 106)

NHPA requires federal agencies to take into account the effects of their undertakings on historic properties. This process, commonly referred to as Section 106 process, provides for review of any federally licensed, financed, or assisted undertaking. Because funds from a federal agency (the United States Department of Transportation, Federal Transit Administration [FTA]) would be used to achieve the project, this assessment of cultural resources was prepared pursuant to Section 106 of NHPA.

Due to the WTC Site being within and near the project locations of their respective proposed undertakings, FTA, Federal Highway Administration (FHWA) and Lower Manhattan Development Corporation (LMDC) coordinated the Section 106 process in determining the

eligibility of the WTC Site for inclusion in the National Register of Historic Places. The coordinated process concluded on March 31, 2004 with the issuance of the Coordinated Determination of National Register Eligibility (Coordinated DOE) finding the WTC Site eligible for listing. As the State Register of Historic Places has the same criteria for evaluation as the National Register, the WTC Site is also eligible for inclusion in the State Register. Each project sponsor is performing its own assessment of its project's effects and identifying mitigation measures, as necessary.

Section 106, as implemented by federal regulations appearing at 36 CFR 800, mandates that federal agencies take into account the effect of their actions on any properties listed on or determined eligible for listing on the National Register of Historic Places (NR) and afford the federal Advisory Council on Historic Preservation (ACHP) a reasonable opportunity to comment on such undertakings. Federal agencies, in consultation with the State Historic Preservation Officer (SHPO), as well as other consulting parties where appropriate, must determine whether the Preferred Alternative would have any effects on the characteristics of a resource that qualify it for the National Register of Historic Places (NR) and seek ways to avoid, minimize, or mitigate any adverse effects. The Section 106 process includes the following:

- All properties within the APE that are included in or eligible for the National Register must be identified in consultation with SHPO. If properties are found that may be eligible for the National Register, but for which no determination has yet been made, the agency consults with SHPO to determine eligibility or ineligibility.
- If there are listed or eligible properties, the potential effect of the proposed project on each property must be evaluated, in consultation with SHPO, to determine if the project would have adverse effects on them by applying the criteria of adverse effect (36 CFR § 800.5(a)). In general, a proposed project is deemed to have an adverse effect if it would diminish the characteristics of the property that qualify it for inclusion in the National Register.
- If the analysis indicates that the proposed project would have an adverse effect, ACHP is notified, and SHPO and other consulting parties are consulted to seek concurrence on ways to avoid, minimize, or mitigate effects. This mitigation is typically implemented through either a Memorandum of Agreement (MOA) or Programmatic Agreement. ACHP may choose to participate in the consultation when there are substantial effects on important historic properties, when a case presents important questions of policy or interpretation, when there is a potential for procedural problems, or when there are issues of concern to Native Americans. ACHP must be invited to participate when the federal agency sponsoring the project requests ACHP's involvement, when the project would have an adverse effect on a National Historic Landmark (NHL), or when a Programmatic Agreement will be prepared. Programmatic Agreements may be used when effects on historic properties are similar and repetitive or are multi-state or regional in scope, when effects on historic properties cannot be fully determined prior to approval of an undertaking, or where other circumstances warrant a departure from the normal Section 106 process, among other reasons. In addition, the federal agency sponsoring the project may request an advisory opinion if it wishes.
- Execution of the MOA or Programmatic Agreement and implementation of the terms therein demonstrate that the federal agency has taken into account the effects of the action.

The review under Section 106 can be conducted in coordination with analyses conducted for NEPA, and where consistent with the procedures set forth in 36 CFR 800, information developed for the NEPA environmental review may be used to meet the requirements of Section

106. The views of the public are essential to inform federal decision-making in the Section 106 process and, therefore, the public should be made aware of, and given the opportunity to comment on, the project and its effects on historic properties. An agency may use its procedures for public involvement under NEPA to satisfy the requirements of Section 106, if those procedures provide adequate opportunities for public involvement consistent with 36 CFR 800. In the case of the Permanent WTC PATH Terminal, the FTA is coordinating its Section 106 process with the other federal agencies carrying out Lower Manhattan Recovery Projects and is using this NEPA review to provide additional opportunities for comment by the public, SHPO, ACHP, and a broad range of consulting parties. As described in Section E, "Mitigation," the Section 106 process is ongoing for this project.

In addition, Section 110 of NHPA addresses federal agencies' responsibility to preserve historic properties. Section 110(f) mandates additional protection for NHLs by requiring that federal agencies exercise a higher standard of care when considering undertakings that may directly and adversely affect NHLs.

SECTION 4(F) OF THE U.S. DEPARTMENT OF TRANSPORTATION ACT

Historic properties are also protected under Section 4(f) of the Department of Transportation Act of 1966.[1] Section 4(f) prohibits actions by the Secretary of Transportation that require "use" of a historic property that is listed on or eligible for inclusion on the National Register, unless a determination is made that there is no feasible and prudent alternative to the use of such land and all possible planning has been undertaken to minimize harm to the 4(f) property. For historic properties, "use" includes direct physical impacts, such as demolition or removal of part of a historic property. It also includes adverse contextual impacts (these can result in "constructive use," when changes caused by the project that are near the historic structure cause a substantial impairment in the historic resource's important qualities). Constructive use could occur from such changes as noise, visual intrusion, or other such elements that would significantly alter the setting of the historic resource. A Section 4(f) Evaluation has been prepared and is included in Volume I of this Environmental Impact Statement (EIS).

STATE HISTORIC PRESERVATION ACT

SHPA closely resembles NHPA, and requires that state agencies consider the effect of their actions on properties listed on or determined eligible for listing on the State Register of Historic Places. Compliance with Section 106 satisfies the requirements of SHPA, set forth in Section 14.09 of the New York State Parks, Recreation and Historic Preservation Law.

NEW YORK CITY LANDMARKS LAW

The New York City Landmarks Preservation Commission (LPC) designates historically significant properties in New York City as NYCLs and/or NYCHDs, following the criteria provided in the *Local Laws of the City of New York, New York City Charter, Administrative Code, Title 25, Chapter 3*. Properties designated as NYCLs or NYCHDs are protected under the New York City Landmarks Law, which requires LPC review and approval before any alterations or demolition can occur. Although the New York City Landmarks Law is not applicable to the

[1] Section 4(f) has been recodified as Section 303 of Title 49 of the United States Code as well Section 138 of Title 23, although it is commonly referred to as Section 4(f).

Permanent WTC PATH Terminal, potential impacts to NYCLs and NYCHDs have been considered.

AREA OF POTENTIAL EFFECT

SHPO has concurred with the APEs defined below for archaeological and historic resources (see Appendix B).

ARCHAEOLOGICAL RESOURCES

For archaeological resources, the APE is generally the area to be excavated by the Preferred Alternative, since this is the area where any artifacts or features could be disturbed (see Figure 6-1). For the Preferred Alternative, the APE for archaeological resources includes a portion of the eastern half of the WTC site (east of the 1 and 9 subway line). The western half of the WTC site (the bathtub), where the proposed tracks, platforms, and mezzanine would be located, was excavated down to bedrock during construction of the WTC, and again during the recent demolition and debris removal as part of the recovery from the attacks. As a result, the bathtub has no potential for archaeological resources.

The APE for archaeological resources also includes the location where a below-grade pedestrian concourse would extend beyond the boundary of the WTC site and cross beneath Route 9A to the World Financial Center (WFC) in Battery Park City (BPC). As described in Chapter 2, "Project Alternatives," the Draft EIS (DEIS) considered an alternative (since dismissed) that would have involved the construction of a below-grade pedestrian concourse beneath Church and Liberty Streets, terminating within Liberty Plaza. The APE for archaeological resources therefore was originally delineated to include portions of Church and Liberty Streets and Liberty Plaza.

Archaeological resources are evaluated through a three-step process. The first step, Phase 1, consisted of documentary research into the history of the site to determine the likelihood that archaeological resources may be present within the APE. This step was divided into two phases: Phase 1A, which required identifying areas that may contain archaeological resources, and Phase 1B, which would involve subsurface testing to try to determine whether any resources are actually present. Phase 1A documentary research has been complete, while Phase 1B subsurface testing has been recommended for certain areas of the Project Site. If the Phase 1B testing indicates that resources are present, then Phase 2 investigations would take place. Phase 2 would consist of more extensive subsurface investigations and additional research to establish the age, integrity and research potential of the resources, and whether they may be eligible for the Registers. A third step, Phase 3, would be considered the mitigation phase; mitigation may consist of either avoidance of the resource or data recovery in the form of a full-scale excavation and documentation.

HISTORIC RESOURCES

To account for contextual and visual effects, as well as possible construction-related structural damage, the APE for historic resources was defined as the Project Site and the adjacent area within approximately two blocks of the Project Site. Thus, the APE is generally bounded by Barclay Street to the north, Albany and Thames Streets to the south, the limits of the Route 9A right-of-way to the west and Broadway to the east (see Figure 6-1).

Identification of Historic Resources

Once the APE was defined, a list of officially recognized historic resources within the APE was compiled. This included NHLs; other properties or districts listed on the State and National Registers of Historic Places (S/NR) or properties determined eligible for such listing; and New York City Landmarks (NYCL) or Historic Districts (NYCHD), or properties pending NYCL or NYCHD designation. A list of potential historic resources within the APE was also compiled. These were identified based on field surveys of the APE and, where available, information from historical societies or preservation organizations with knowledge of the area. Potential historic resources comprise properties that may be eligible for listing on the S/NR and/or designation as NYCLs.

The National Register Criteria for Evaluation are found in 36 CFR 60. Following these criteria, districts, sites, buildings, structures, and objects are eligible for the S/NR if they possess integrity of location, design, setting, materials workmanship, feeling, and association, and:

A. that are associated with events that have made a significant contribution to the broad patterns of our history; or

B. that are associated with the lives of significant persons in our past; or

C. that embody the distinctive characteristics of a type, period, or method of construction; that represent the work of a master; that possess high artistic values; that represent a significant and distinguishable entity whose components may lack individual distinction; or

D. that have yielded, or may be likely to yield, information important in history or prehistory.

Properties that have been constructed within the last 50 years are ordinarily not eligible. Determinations of eligibility are made by SHPO. Generally, all properties that are listed on the National Register are listed on the State Register, which has the same criteria for evaluation as the National Register.

Buildings, properties, or objects are eligible for designation as a NYCL or NYCHD when a part is at least 30 years old. Landmarks have a special character or special historical or aesthetic interest or value as part of the development, heritage, or cultural characteristics of the city, state, or nation. There are four types of landmarks: individual, interior, historic district, and scenic.

The identification of historic resources for this project was unique due to the historic events of September 11, 2001. As described above, FTA, FHWA, and LMDC issued a Coordinated DOE regarding the WTC site's eligibility for inclusion in the National Register. SHPO concurred with this determination and found the WTC site eligible for listing in the National Register (see Appendix B). As the State and National Registers have the same criteria for evaluation, the WTC Site is also eligible for inclusion in the State Register.

In addition to the resources with official designation or status, a number of other potential historic resources have been identified by the Lower Manhattan Emergency Preservation Fund (LMEPF), a consortium of historic preservation organizations that was formed in response to the terrorist attacks of September 11, 2001. This consortium includes the Municipal Art Society, the National Trust for Historic Preservation, the New York Landmarks Conservancy, the Preservation League of New York State, and the World Monuments Fund. The LMEPF produced a map, entitled *Corridors of Concern*, which shows potential historic resources in addition to the officially recognized (or known) resources. Information obtained from this map was used to assist in the identification of potential historic resources. SHPO and LPC have

determined that some of these resources are S/NR-eligible and NYCL-eligible, and these resources have been included in Table 6-1.

ASSESSMENT OF EFFECTS ON HISTORIC RESOURCES

Once the historic resources in the APE are identified, the effects of the project on those resources are assessed. As described above, potential effects may include both direct physical effects and indirect contextual effects. Direct effects could include physical destruction, damage, or alteration of a historic resource. In addition, indirect effects, such as changes in the appearance of a historic resource or in its setting—including introduction of incompatible visual, audible, or atmospheric elements to a resource's setting—are considered.

FTA began its Section 106 process in September 2003, concurrent with scoping for the Permanent WTC PATH Terminal. In December 2003, FTA began its coordinated Section 106 process with FHWA (lead agency for the Route 9A Project and LMDC (lead agency for the WTC Memorial and Redevelopment Plan). In December 2003, the three federal agencies jointly notified the SHPO and ACHP concerning these three Lower Manhattan undertakings and identified potential consulting parties to the Section 106 process. In January and February 2004, FTA, FHWA and LMDC jointly hosted two meetings with consulting parties to discuss the projects and in particular the evaluation of the WTC Site for eligibility for inclusion in the National Register of Historic Places. Consulting parties were also offered opportunities to comment on draft versions of the Coordinated DOE, which was issued in final form on March 31, 2004. At this point, the coordinated process effectively ended, with each lead agency to meet the remainder of its Section 106 responsibilities separately as appropriate to its respective undertaking.

FTA identified the APE for the Permanent WTC PATH Terminal and by letter of February 25, 2004 requested SHPO concurrence with its proposed APE. The SHPO indicated its concurrence through its letter of March 19, 2004. FTA has identified 21 historic properties within the APE as described below, and as shown on Figure 6-1 and Table 6-1. Areas of potential archaeological sensitivity within the APE are shown on Figure 6-2.

As discussed in Section D, "Probable Impacts of the Project Alternatives," FTA finds that the Preferred Alternative will have adverse effects on historic properties. FTA has coordinated extensively with SHPO, ACHP, and consulting parties in the identification of measures to resolve these adverse effects (see Section E, "Mitigation," for more information). Results of this coordination and consultation form the basis for the MOA executed among FTA, SHPO, ACHP, and PANYNJ for the Permanent WTC PATH Terminal (see Appendix B).

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

PRE-SEPTEMBER 11, 2001 BASELINE CONDITIONS

ARCHAEOLOGICAL RESOURCES

It is assumed that the potential for archaeological resources would be the same in the pre-September 11, 2001 conditions analysis as described below in "Changes in the Affected Environment Since September 11, 2001." The potential for archaeological resources was limited due to construction activity that took place on the Project Site and surrounding area prior to September 11, 2001.

Figure 6-2

PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Areas of Potential Archaeological Sensitivity

HISTORIC RESOURCES

Project Site

Prior to September 11, 2001, the Project Site was occupied by a WTC PATH Terminal, which included a track and platform level, an associated mezzanine/fare-zone level, and sub-grade pedestrian connections to adjacent streets, subways, and the buildings of the WTC. Access to the mezzanine and platform levels was located on the eastern portion of the Project Site within the WTC concourse. The track and platform and mezzanine levels were located on the western half of the site (west of the 1 and 9 subway line), below the WTC Towers 1 and 2. The tracks connected to the Hudson River tunnels beneath Route 9A and extended west under the Hudson River to New Jersey. Below ground, remnants of the former Hudson and Manhattan (H&M) Terminal existed in an altered state. Used as truck ramps and for storage, they were not publicly accessible.

As of September 11, 2001, none of the PATH facilities or WTC buildings on the Project Site were listed on or determined eligible for listing on the S/NR or designated as a NYCL.

Area of Potential Effect

In the pre-September 11, 2001 conditions analysis, the approximately 16-acre WTC, built by the Port Authority of New York and New Jersey (PANYNJ) between 1966 and 1981, comprised six buildings, including the 110-story Twin Towers (1 and 2 WTC). These 1,350-foot-tall aluminum-clad towers (excluding the 345.1-foot antenna) were the tallest buildings in the world when completed in 1972 and 1973. Other buildings located on the WTC site included a 22-story hotel (3 WTC), two nine-story buildings (4 and 5 WTC), and an eight-story U.S. Customs House (6 WTC). These buildings were situated around the Austin J. Tobin Plaza, which was decorated with several sculptures by prominent artists. A concourse was located directly below the plaza and consisted of a retail mall and transportation hub. A pedestrian bridge over Route 9A connected the northern part of the WTC with the commercial core of BPC. As of September 11, 2001, there were no known historic resources located on the WTC Site.

Prior to September 11, 2001, the block at the corner of Liberty Street and Route 9A was an active parking lot and the site of the St. Nicholas Greek Orthodox Church, destroyed on September 11, 2001. This small Greek Orthodox church stood at 155 Cedar Street, south of the WTC. Established in 1916 by Greek immigrants, it was only 35 feet tall with a rooftop bell cote. The church was notable for its small scale and its icons, which were a gift from the last czar of Russia, Nicholas II. The block to the east was occupied by a 39-story office building at 130 Liberty Street. Located directly across Liberty Street from 2 WTC, it was a fully occupied office tower with ground-floor retail. It had a plaza with a fountain, above which was an additional plaza level that was originally intended to connect to the plaza level at the WTC.

It is assumed that all historic buildings that were damaged on September 11, 2001 would not have been damaged and would still be occupied as they were on September 11, 2001. The Federal Office Building/U.S. Post Office would be occupied with office tenants and the Church Street Station of the post office would be open and serving its customers. The Barclay-Vesey Building would be undamaged.

It is assumed that the identification of known and potential resources would be the same in the pre-September 11, 2001 conditions analysis as described below in "Changes in the Affected Environment Since September 11, 2001." Although several resources were listed on or determined eligible for listing on the National Register or designated as a NYCL or NYCHD after Septem-

ber 11, 2001, these resources would have been determined eligible or designated in any event because their characteristics that qualify them for listing were not altered.

CHANGES IN THE AFFECTED ENVIRONMENT SINCE SEPTEMBER 11, 2001

ARCHAEOLOGICAL RESOURCES

The following analysis regarding the potential for archaeological resources on the WTC site was based on data obtained from a Phase IA Archaeological Assessment of the WTC, prepared in October 2003 and a Topic Intensive Study of the WTC Site, prepared in March 2004. Information regarding the potential for archaeological resources in the Route 9A roadbed was obtained from prior documentation for the *Route 9A Reconstruction FEIS*. Copies of these reports, as well as relevant SHPO correspondence, are included in Appendix B.

Project Site

Prehistoric Resources. Prior to European contact in the early 17th century, Native Americans speaking a Munsee dialect of the Eastern Algonquin language inhabited Manhattan Island. Native Americans referred to the island of Manhattan as "Minna-atn" which meant "Island of Hills." The first contacts between Native Americans and Europeans occurred when early explorers began to trade with the native population. Dutch trading expeditions had been visiting the Hudson River for many years prior to the founding of New Amsterdam at the southern tip of Manhattan in 1626. These groups made contact with the native population; Robert Juet, who traveled with Henry Hudson on his 1609 voyage, provides in his journal a description of the native population and their trading practices. Dutch colonization in Manhattan began in earnest in 1625 when an expedition of farmers from the Dutch West India Company arrived at the southern tip of Manhattan with the purpose of building a fort and laying out nine Company farms.

Prior to landfilling activities in the 18th and early 19th centuries, the Hudson River shoreline originally ran approximately along the path of Greenwich Street. Research on the Paleo-shoreline indicates the possibility of a bay from Cedar Street to north of the WTC and an irregular shoreline forming a spit of land near Vesey Street at about 40 feet below current sea level.

There is little likelihood that precontact archaeological resources have survived within the Project Site. West of Greenwich Street, excavation for the bathtub extends about 70 feet below grade, below the lowest level that precontact deposits could have survived (about 40 feet below grade). East of Greenwich Street, it is likely that precontact resources would have been destroyed by basement construction in these areas as well as construction activities associated with the WTC.

Therefore, the Project Site is not considered sensitive for prehistoric archaeological resources.

Historic Period. Prior to 1700, a large portion of the Project Site was either under water or was undeveloped farmland. During the Dutch period, a wooden ship called the *Tyjger* burned and was abandoned along the shoreline in 1613.

The first known structures on the Project Site were a house and windmill belonging to Peter Mesier. Shown on the Miller Plan (1696), they were located in the area that is now west of Church Street between Liberty and Cortlandt Streets. Landfilling along the Hudson River shoreline began around the turn of the 18th century. Between 1699 and 1701 several entrepreneurs

built docks on the three blocks between Cedar and Cortlandt Streets and Greenwich Street and Washington Street.

Activity along the Hudson River waterfront accelerated in the 18th century and continued through the 19th century. Many streets were planned and developed during this period and the busy waterfront supported many successful business ventures. By 1852 all the streetfronts within the APE had been solidly filled with buildings.

The Project Site was disturbed by construction of the 1 and 9 subway lines and the Hudson & Manhattan (H&M) Railroad and its Terminal on the west side of Church Street between Cortlandt and Fulton Streets. During construction of the subway (1916), the remains of a wooden ship thought to be the *Tyjger* were found in the excavation of Greenwich Street at Dey Street.

During the 1960s, the Project Site was extensively disturbed by construction of the WTC. The entire area west of Greenwich Street and the 1 and 9 subway was excavated to bedrock, 70 feet below grade to create the so-called bathtub where the Twin Towers along with the hotel and 6 WTC stood. In 1967 during excavation for the WTC, archaeologists attempted to find the rest of the *Tyjger*, but their efforts were unsuccessful.

Areas of Potential Sensitivity. A Phase IA Archaeological Assessment for the Project Site (included in Appendix B) found the following areas to be sensitive and warrant further consideration:

- At the northeast corner of the Project Site: former Lots 8-17 on former Block 85 (south side of Vesey Street between Greenwich and Church Streets, see Figure 6-2).
- At the southeast corner of the Project Site: Former lots 5, 6, and 10 on former Block 60 (north side of Liberty Street between Greenwich and Church Streets, see Figure 6-2).

The Topic Intensive Study for the WTC Site (included in Appendix B) concluded that the three lots on Liberty Street and the 10 lots on Vesey Street appear to possess potential archaeological significance. Each of the lots was occupied by a household or business for an extended period of time spanning the 1750s through the 1850s. The lots were used for both residences, businesses, and a combination of residences and businesses, where the proprietor lived and worked at the same location. Archaeological resources associated with occupations on these 13 historic lots have the potential to answer a variety of research questions pertaining to use and occupation of home lots by different types of individuals and businesses in Lower Manhattan during the second half of the 18th and first half of the 19th century.

These areas were located outside the former WTC construction footprint and have the potential to contain shaft features (such as privies, cisterns, wells, and cesspools) predating the 1850s that may have survived under former basements. Lots with basements 20 feet or more below grade have a lesser likelihood of shaft feature preservation.

Route 9A Connection

There is one known archaeological resource in the area where the pedestrian concourse to the WFC would be located—the Hudson River Bulkhead (S/NR-eligible). The bulkhead and its associated structural systems were built between 1871 and 1936 by the New York City Department of Docks. The majority of the construction consisted of masonry walls on a variety of foundation systems, with quarry-faced ashlar granite block forming the visible face along most of the armored frontage. Design of the bulkhead was the responsibility of George B.

McClellan, a Civil War general, who became the first Engineer-in-Chief of the Department of Docks. McClellan's plans contemplated the creation of a 250-foot-wide marginal street, from which 60- to 100-foot-wide piers with cargo sheds would project 400 to 500 feet around 150- to 200-foot-wide slips. Initiated to respond to the deteriorated, congested, and silt-filled condition of the waterfront, the carefully built granite walls created a consistent monumental surface to the waterfront that reinforced an image of New York City's commercial prominence. As property was acquired and as commerce warranted, the city built the bulkheads, built or rebuilt pier substructures, and leased redeveloped areas to private companies, which were usually responsible for piershed and headhouse construction. The bulkhead runs from the Battery to West 59th Street. The portion of the bulkhead located within the study area is below-grade along the western edge of Route 9A.

In the area between Dey and Fulton Streets, where the pedestrian concourse to the WFC would be located, 16 potential historic-period archaeological sites were identified in documentation prepared for the *Route 9A Reconstruction FEIS* (see Appendix B). No potential prehistoric sites were identified in this area. (This number includes sites listed as Cortlandt-Dey on the south and Fulton-Vesey on the north.) Of these, 15 were piers, wharves and pier sheds; all of these were eliminated from further consideration due to lack of archaeological visibility and lack of research potential (SHPO letter 8/12/92). The other site was a crib bulkhead at Dey Street, which was eliminated due to lack of research potential (SHPO letter 8/12/92).

HISTORIC RESOURCES

Project Site

The Project Site is located within and near the limits of the approximately 16-acre WTC site, which has been found to be S/NR-eligible. A street level access point and a below-grade pedestrian concourse would extend beyond the Project Site, connecting to the Winter Garden at the WFC. The WFC is located in BPC, west of Route 9A, opposite the WTC site. The Winter Garden is a large glass-enclosed public atrium and is one of several modern structures included in the WFC. It was severely damaged on September 11, 2001 and has since been reconstructed.

The temporary WTC PATH station opened in November 2003. Its entrance is located at the northeast portion of the WTC site. At Fulton Street, the canopy of the temporary WTC PATH station has a sculptural form, with two wings rising from a central truss supported on two vertical trusses. The tracks of the temporary WTC PATH station curve around the south end of the bathtub, passing into the new structure of the temporary station. The temporary WTC PATH station's mezzanine level, station platforms, and rail tracks are located on the western portion of the site. The 1 and 9 subway line also bisects the Project Site. Additionally, a wide area along the east side of the Project Site is paved with concrete. Sidewalk viewing areas are located along Church Street south of the PATH entrance and on Liberty Street. Aside from the viewing areas and the temporary WTC PATH station, the remainder of the Project Site remains excavated or under construction and is not accessible to the public.

Limited portions of the former H&M Terminal still exist below grade on the WTC site. Designed by Clinton & Russell, and constructed in 1908–09, it consisted of two 19-story Renaissance Revival towers that were linked together below ground by a three-level rail terminal. It occupied a two-block-long site on Church Street between Cortlandt and Fulton Streets. The terminal was linked to the Hudson Tubes—two cast-iron ring tunnels built under the Hudson River. In connection with the construction of the WTC, a new PATH terminal was built west of the H&M Terminal. Although the H&M Terminal office towers were demolished, the Hudson

Tubes were still used, but were redirected to swing out farther apart from each other to accommodate the longer length of the new terminal. As the terminal was located west of the H&M Terminal and at a lower grade, the H&M Terminal was able to maintain normal service during construction of the new facility. The WTC PATH Terminal opened in 1971, at which time the H&M Terminal was closed. Unused remnants of the Hudson Tubes were converted to truck ramps, and portions of the former terminal were used for truck loading, parking, and storage.

The WTC PATH Terminal and the PATH tunnels were catastrophically destroyed as a result of the terrorist attacks on September 11, 2001. Some portions of the underground levels of the former H&M Terminal were damaged but remained intact. SHPO determined that the remaining portions of the former H&M Terminal and the cast-iron tubes leading from the station do not meet the criteria for listing on the National Register due to a loss of historic integrity (letter dated October 16, 2003).

Area of Potential Effect

Known Resources

There are several known historic resources located in the APE. These resources are described below. They are also listed in Table 6-1 and mapped on Figure 6-1.

WTC Site (S/NR-eligible)

The WTC Site is an approximately 16-acre parcel bounded by Vesey, Church and Liberty Streets and Route 9A. As detailed in the Coordinated DOE (see Appendix B), the WTC Site is significant as the locus of the events of September 11 and the significance of those events and their aftermath to American history makes the WTC Site eligible for listing on the State and National Registers, even at this early date. Some elements remaining on the site help convey the events of September 11 and their aftermath. The Coordinated DOE identifies the following elements in particular as contributing to the significance of the WTC Site: the truncated box-beam column bases that help define the perimeter or "footprints" of the former Twin Towers; the slurry walls that form the sides of the underground bathtub for the Twin Towers; the remnants of the parking garage, containing slabs and interior columns charred with smoke; the beams forming a cross erected by recovery workers; the portion of the concrete steps and escalator ramp from Vesey Street to the subway; and the remaining portion of the passageway to the E subway line.

Artifacts recovered from the WTC Site following the attacks currently exist at off-site locations, including the New York State Museum in Albany and Hangar 17 at John F. Kennedy International Airport. Because these off-site artifacts are not physically located on the WTC Site and do not convey the significance of the site, they are not included in the Coordinated DOE. However, the Keeper of the National Register of Historic Places has indicated in a letter to the ACHP (dated July 18, 2004), that artifacts returned to the WTC Site in the future could be considered contributing elements of this historic property if they are returned and found to convey significance (see the Coordinated DOE in Appendix B for a discussion of off-site artifacts).

Notes: Corresponds to Figure 6-1.
NHL: National Historic Landmark.
SR: New York State Register of Historic Places.
NR: National Register of Historic Places.
S/NR-eligible: Site has been found eligible for listing on the New York State and National Registers of Historic Places.
NYCL: New York City Landmark.
NYCL-eligible: LPC has determined that the site appears eligible for NYCL designation.
* The United States Realty Building is listed on the SR only. It is eligible for listing on the NR.

In addition, the Coalition of 9/11 Families has requested that the National Park Service (NPS), which administers the NHL program, consider the WTC Site for NHL status. The NHL program was authorized by the Historic Sites Act of 1935 (Public Law 74-292). NHL criteria (36 CFR § 65.4[a] and [b]) differ from National Register criteria and establish a stringent test for national significance and high historical integrity. NPS has indicated that they will not consider this request until the Project's Section 106 review process and other Section 106 processes related to the WTC Site are completed.

Barclay-Vesey Building (S/NR-Eligible, NYCL)

Built between 1923 and 1927, the Art Deco Barclay-Vesey Building (140 West Street) occupies the full block bounded by Barclay Street, Washington Street, Vesey Sreet, and Route 9A, and overlooks the WTC Site. It is considered one of the most significant structures in the history of skyscraper design, since it was the first building in New York City to make the most of the requirements of the 1916 Zoning Resolution, leading to the tower's dramatic massing. Designed by Ralph Walker of McKenzie, Voorhees & Gmelin as an office building and switching center for the New York Telephone Company, this 32-story brick, limestone, and terra cotta structure consists of an 18-story parallelogram base and an 11-story square tower (see Figure 6-3). For 10 stories, the base rises flush with the lot lines. Above the 10th floor, there are setbacks on the north and south façades and light courts on the east and west façades. Above the base, the tower is oriented to the Manhattan grid street pattern. Multiple setbacks above the 10th floor serve to further relieve the building's bulk. Flat piers provide verticality and on the tower they create buttresses that cap the structure. There are limestone cornices on each setback, and on the first two floors there are terra cotta spandrel panels, and window and door enframements of intricately carved reliefs of people, animals, and vegetation. The ground floor of the Vesey Street façade is an arcade.

The Barclay-Vesey Building suffered façade and structural damage as a result of the collapse of 1 WTC and 7 WTC. Repair work is ongoing and it is partially reoccupied.

Federal Office Building/U.S. Post Office (S/NR)

This building, located at 90 Church Street, was designed by Cross & Cross and Pennington, Lewis & Mills and was constructed in 1934–38. The massive limestone building is 15 stories tall and combines Classical Revival and Art Deco details, as well as exterior sculptural reliefs by Carl Paul Jennewein (see Figure 6-3). It occupies the full block bounded by West Broadway and Barclay, Vesey, and Church Streets, and also overlooks the WTC Site across Vesey Street. The building has been closed for repair, cleaning, remediation of potentially hazardous materials, and interior reconstruction.

St. Peter's Roman Catholic Church (S/NR, NYCL)

Located at 22 Barclay Street, this Greek Revival granite church is home to the oldest Roman Catholic parish in New York City. It was designed by John R. Haggerty and Thomas Thomas in 1836-40, replacing an earlier building dating from 1785. It has a temple-like front with six Ionic columns (see Figure 6-4).

Former St. Peter's School (S/NR-eligible)

East of St. Peter's Church at 16 Barclay Street, a five-story brick Greek Revival school building was erected for St. Peter's School ca. 1838. It is three bays wide and is topped with a mansard roof with three pediment dormers (see Figure 6-4).

30 Vesey Street (S/NR-eligible)

The 18-story brick Renaissance Revival building at 30 Vesey Street has a tripartite design of base, shaft, and capital. Fluted pilasters embellish its two-story base, and additional ornamentation is found at the upper stories. It was constructed in 1914.

Old New York Evening Post Building (S/NR, NYCL)

Robert D. Kohn designed this 13-story limestone-faced building, located at 20 Vesey Street, in 1906–07. It was erected as the offices and printing plant of the *New York Evening Post*. It is a rare example of a New York City building inspired by the early 20th-century Central European artistic reform movement known as the Vienna Secession. Its refined classicism, rational expression of structure, and stylized ornament are suggestive of Viennese precedents. Notable features of the building include four statues on the 10th floor known as the *Four Periods of Publicity*—two are by Gutzon Borglum, the sculptor of Mount Rushmore, and two are by Estelle Rumbold Kohn, the architect's wife.

New York County Lawyer's Association (S/NR, NYCL)

An example of the 18th-century English Georgian Revival style, this four-story white limestone building is a late work of Cass Gilbert, having been designed in 1929–30. It is located at 14 Vesey Street and was commissioned by the New York County Lawyer's Association, an organization that had been founded in 1908 to serve the public interest and the legal profession.

Astor Building (S/NR-eligible)

The seven-story Renaissance Revival commercial building at 217 Broadway was designed by Charles Platt in 1915. It has a stone façade and lacks ornamentation. The building is crowned by a bracketed cornice.

Transportation Building (S/NR-eligible)

Designed by York & Sawyer in 1926–27, this 44-story skyscraper is located at 225 Broadway. It rises straight to the 23rd floor, continues eight stories with narrow setbacks, then a rectangular tower rises an additional 13 floors. It has a four-story stone base with tan brick upper stories and Lombardic details.

African Burial Ground and the Commons Historic District (NHL, S/NR, NYCHD)

Bounded by Duane Street, Park Row, Broadway, and Centre Street, this district incorporates both the Commons—pastureland set aside by the Dutch government in colonial New Amsterdam—and the 18th-century African Burial Ground. The Commons later became a site for parading troops, public gatherings, celebrations, and executions. A portion of the Commons became a public park in the 1780s and was later incorporated into a park setting for City Hall. The section of the Commons between Chambers and Duane Streets became a burial ground for African slaves and freed men and women in the 18th century and possibly earlier. The cemetery was uncovered during investigations for the construction of a federal office building. Portions of the burial ground were completely excavated to construct the government building, but other sections were preserved in situ as a memorial to New York's earliest African residents.

St. Paul's Chapel and Graveyard (NHL, S/NR, NYCL)

St. Paul's Chapel, located at Broadway and Fulton Street, was erected between 1764 and 1766; its porch was built in 1767–68 and its tower was designed by James C. Lawrence in 1794. It is Manhattan's oldest surviving church and is also considered one of the finest Georgian buildings in the nation. It is a simplified version of James Gibbs's Saint Martin-in-the-Fields on Trafalgar Square in London. It was built of local stone with brownstone trim. It has a modest portico on its towered west façade, which faces the adjacent 18th-century graveyard. The Broadway elevation features an imposing brownstone Ionic porch, which was part of the original plan but was not built until 1767–68 (see Figure 6-4). Although the design of the church is often ascribed to

St. Paul's Chapel (Broadway and Fulton)
and the former AT&T Company Building (195 Broadway)

Figure 6-4
Known Historic Resources

Thomas McBean, there is no evidence to support this theory. George Washington worshipped at the church during the brief period when New York was the nation's capital. During the recovery effort at the WTC Site, the chapel served as a refuge for rescue workers.

Former American Telephone & Telegraph (AT&T) Company Building (S/NR-eligible, NYCL-eligible)

Designed by William Welles Bosworth and built in three sections between 1912 and 1923, this 29-story neo-Classical Revival commercial office building is located at 195 Broadway. It has been described as a square-topped layer cake, as its façade consists of eight Ionic colonnades, with three stories located within each set (see Figure 6-4). It is clad with Vermont granite and has a Doric colonnade at the lower story. It is reported to have more classical columns than any other façade in the world. Its tower rises to a stepped crown modeled on the Mausoleum of Halicarnassus. Bronze panels above the Broadway entrances were designed by the sculptor Paul Manship. It has a notable lobby with Greek Temple-like rows of Doric columns.

Fulton Street Station (S/NR-eligible, NYCL)

The underground subway station at Fulton Street is one of several under- and above-ground stations built as part of Contract 1 of the Interborough Rapid Transit Company's first subway in Manhattan. This first section of the subway, which ran from City Hall to Grand Central Terminal and then ran west and along Broadway to the Bronx, was built between 1899 and 1904 under the direction of Chief Engineer William B. Parsons. The ornamentation of the stations, consisting primarily of white tile with light-colored brick and decorative mosaic sign panels and terra cotta and faience plaques, was designed by Heins & La Farge. The Fulton Street Station was restored in 1987 by Lee Harris Pomeroy & Associates. It features ceramic tile plaques of Robert Fulton's steamboat the *Clermont*.

Former East River Savings Bank (S/NR-eligible, NYCL-eligible)

Currently occupied by a department store, the five-story former bank building located at 26 Cortlandt Street was designed by Walker & Gillette in 1931–1934. It has Classical and Art Deco details with stainless-steel winged eagles over the entrances (see Figure 6-5).

United States Realty Building (SR, NR-eligible, NYCL)

Designed by Francis H. Kimball in 1904–07, this skyscraper at 115 Broadway, as well as the Trinity Building at 111 Broadway, were designed with Gothic details to harmonize with Trinity Church, located to the south. Both buildings are faced with limestone and feature towers, gables, and delicately carved ornament. Construction of both buildings was a major undertaking, causing the relocation of Thames Street as well as the construction of caissons 80 feet into the marshy subsoil.

Beard Building (S/NR-eligible, NYCL-eligible)

Oswald Wirz designed the 12-story Beard Building at 125 Cedar Street (a.k.a. 120 Liberty Street) as an office building. Constructed in 1895–97, it is a through-block, brick and stone building with Romanesque Revival-style façades (see Figure 6-5). It has a two-story stone base composed of pilasters and deeply recessed window bays; the north façade of the base is clad in limestone, while the south façade appears to be clad in sandstone. On the shaft, wide piers frame corner window bays and create a wide central bay broken up by thin, closely spaced mullions. An entablature caps the shaft. The two-story building capital contains pedimented windows. A

bracketed cornice crowns the building. Converted to residential use long before September 11, 2001, it has been restored and reoccupied except for the ground floor on Liberty Street.

114-118 Liberty Street (S/NR-eligible)

This 11-story Renaissance Revival-style building was constructed in 1900–01 and designed by John T. Williams (see Figure 6-5). Due to the irregular lot shape, the through-block loft building is three bays wide on Liberty Street and two bays wide on Cedar Street. The main façade fronts Liberty Street overlooking the WTC Site. It has a two-story rusticated stone base and a brick shaft crowned with a modillioned cornice. The base contains an entrance porch, arched show windows with keystones, and a frieze. Projecting cartouches and an entablature mark the mezzanine (third) story. The upper floors are articulated with brick pilasters, spandrels, and mullions. At the two-story capital, swags crown the double-height piers, and the top-floor windows are arched. The Cedar Street façade is divided into a rusticated base, a shaft composed of piers and window bays, and a cornice-crowned capital, but it is less ornate. Converted to residential use prior to September 11, 2001, it is currently being restored to residential use.

21-23 Thames Street (S/NR-eligible)

This five-story brick tenement was built in 1872 by John Lerscher. It features a galvanized iron cornice and was originally designed to house three families on each of its upper stories.

90 West Street (S/NR-eligible, NYCL)

Designed by Cass Gilbert and built in 1905–07, the 90 West Street Building is among the most important early 20th century skyscrapers in New York City, and the aesthetic precursor of Gilbert's Woolworth Building from 1910–13. The 23-story former commercial office building is also the earliest example of the use of Gothic detail on a skyscraper with distinctly vertical massing. It has a C-shaped plan with a light court facing east and its primary façade fronting on Route 9A. Its north elevation faces the WTC Site across Liberty Street. Above a two-story granite base, the façades of the shaft are clad in white terra cotta with modest marble and polychromed terra cotta trim. The shaft is articulated with recessed window bays and clustered columns that form piers. These piers, along with colonettes between the windows, rise uninterrupted for most of the building's height, creating vertical emphasis. The building's heavy three-story capital is ornately designed as an arcade with engaged columns. A mansard roof with dormers and pinnacles crowns the building. The building was covered in scaffolding for ongoing façade repair on September 11. It was heavily damaged due to burning debris from the WTC. It is being restored and renovated for residential use.

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

This section describes conditions that are or would be expected to exist under the No Action and Preferred Alternatives for the three analysis scenarios (construction period, opening year and design year).

CONSTRUCTION PERIOD (2006)

FUTURE COMMON TO ALL ALTERNATIVES

Initial reconstruction activities associated with the WTC Memorial and Redevelopment Plan would be taking place. It is anticipated that St. Nicholas Church will be reconstructed on the

Former East River Savings Bank, 26 Cortlandt Street

114-118 Liberty Street (left) and the Beard Building at 125 Cedar Street

Figure 6-5
Known Historic Resources

block south of the WTC site. In addition, reconstruction of Route 9A between West Thames Street and Chambers Street will be underway.

As part of the Section 106 process for each of their respective projects, LMDC and NYSDOT have prepared and executed Programmatic Agreements that will continue to guide the design and construction of their projects with respect to potential impacts to historic resources. Furthermore, the Northwest Remnant Subgrade Structures, which were identified in the coordinated DOE for the WTC site, will be removed as part of Freedom Tower's construction. The removal of these structures is being undertaken in accordance with the Programmatic Agreement by LMDC, SHPO, and ACHP.

Both the Barclay-Vesey Building and the Federal Office Building/U.S. Post Office, north of the Project Site, will be repaired, renovated, and reopened. Between these two buildings, 7 WTC will be complete along with its triangular open space on the north side of Vesey Street. A residential building is expected to be complete along Barclay Street, between Broadway and Church Street. The proposed building is expected to be taller than the adjacent small-scale buildings.

NO ACTION ALTERNATIVE

Project Site

Under the No Action Alternative, the temporary WTC PATH station would remain in service. There would be no project-generated construction activities that would affect historic resources.

Area of Potential Effect

It is not expected that this alternative would have any adverse effects on historic resources.

PREFERRED ALTERNATIVE

Project Site

Construction of the Preferred Alternative would begin in 2005 concurrent with other sub-grade work for the proposed redevelopment of the WTC site. Components of the terminal, including the platforms, mezzanine, and certain pedestrian connections, would be completed by the end of 2009. A pedestrian concourse to the WFC would also be constructed.

Construction of the Preferred Alternative may affect potential archaeological resources located on the Project Site. In order to avoid, minimize, or mitigate any adverse effects to potential archaeological resources on the Project Site, PANYNJ would coordinate with LMDC and SHPO prior to the start of construction to determine whether any potentially sensitive areas have already been tested as part of the WTC Memorial and Redevelopment Plan. As described in the MOA executed for the Permanent WTC PATH Terminal, prior to any disturbance of potentially sensitive areas, PANYNJ would—in consultation with SHPO and LMDC, as appropriate—locate, identify, and evaluate the National Register eligibility of archaeological resources in these potentially sensitive areas. If National Register-eligible archaeological resources would be adversely affected by construction of the Preferred Alternative, PANYNJ, in consultation with FTA, SHPO, and LMDC, as appropriate, and the Section 106 consulting parties, would develop and implement an Archaeological Resource Treatment Plan

Construction of a below-grade pedestrian concourse to the WFC may require removal of short segments of the Hudson River Bulkhead between Fulton and Vesey Streets. At this time it is

anticipated that an approximately 40-foot wide segment of the bulkhead would be affected. As described in the executed MOA, PANYNJ would coordinate treatment of the bulkhead with NYSDOT, as appropriate. A plan would be developed to locate and identify intact portions of the bulkhead that would be affected by construction of the below-grade pedestrian concourse. If intact portions of the bulkhead are identified, PANYNJ would, in consultation with SHPO and NYSDOT, prepare a treatment plan for the portions of the Hudson River Bulkhead that would be affected by the Preferred Alternative. The plan would be submitted to SHPO and the Section 106 consulting parties for review and comment prior to its implementation.

Area of Potential Effect

WTC Site

Adverse effects to the WTC site are expected under this alternative, although the extent of these adverse effects has not yet been fully determined. Construction of the Preferred Alternative would not alter the location or setting of the WTC site. However, because it will result in the removal or alteration of remaining remnants and structures on the site, it could diminish the site's integrity of feeling, association, and materials. The following describes the specific impacts of the Preferred Alternative on the various elements of this historic resource. Each of these elements has been addressed in the MOA and specific stipulations regarding the documentation and treatment of the WTC site have been defined (see Appendix B).

- ***Tower Perimeter Column Bases with Other Column Bases and Infrastructure*** (constructed pre-September 11, 2001): There were 84 perimeter columns extending into the bedrock that would outline the North Tower façade, and 73 perimeter columns extending into bedrock that would outline the South Tower façade. The original subgrade column grid in the WTC bathtub was configured to span above the former Hudson & Manhattan tunnels traversing the bathtub, as well as then new PATH tracks (there were 84 perimeter columns for the South Tower appearing above grade). In addition, approximately 34 of the South Tower columns were within the PATH right-of-way area (interspersed with tracks, electrical equipment, and other infrastructure), and 39 were outside the PATH right-of-way area. During the post-September 11, 2001 emergency recovery operations conducted by the City of New York, all of these Tower perimeter columns were truncated such that only the bases remain. During subsequent construction of the temporary WTC PATH station, all of the column bases within the existing PATH right-of-way were either obscured to some extent or removed for installation of the temporary WTC PATH station's track sheds, utilities, duct banks, conduits, and other PATH infrastructure.

  As described in the project's Memorandum of Agreement (MOA), PANYNJ shall, to the maximum extent feasible, preserve in place 84 column base remnants in the North Tower and 39 column base remnants in the South Tower at the existing floor at elevation 242 (58 feet below Sea Level) that outline the footprints of the former Twin Towers at the WTC site and are not located in the PATH right-of-way. However, up to 16 column bases in the North Tower and 3 column bases in the South Tower would be temporarily or permanently removed.

  There would be various site infrastructure elements supporting the Preferred Alternative within the PATH right-of-way, including utility lines traversing the outline of the Tower perimeter column bases, and utility rooms and structures located within the area outlined by the perimeter column bases. Although these would not disturb the perimeter column bases themselves, these elements may somewhat impact visibility and accessibility to the Tower

perimeter column bases. The Preferred Alternative may also include utility lines that cross the footprints of the former North and South Towers at an elevation above the existing floor of the WTC site (Elevation 242 or 58 feet below Sea Level). Under current plans, these utilities would be at Elevation 264 (36 feet below Sea Level). These utility lines could serve the joint infrastructure needs of both the Permanent WTC PATH Terminal and the WTC Memorial and Redevelopment Plan.

The total extent of the North Tower footprint at the lowest level, at approximately elevation 242 (58 feet below sea level) to be permanently occupied by any portion of the Project will be approximately 1,600 square feet and will not exceed 4 percent of the North Tower footprint area. The total extent of the South Tower footprint at the lowest level, at approximately elevation 242 (58 feet below sea level) to be permanently occupied by any portion of the Project will be approximately 21,615 square feet currently occupied by the WTC PATH facility, plus an additional 2,000 square feet required by the Project, and will not exceed 53 percent of the South Tower footprint area.

During the construction of the Preferred Alternative, PANYNJ would construct a temporary track west of the existing Track 5. This temporary track would be used to maintain PATH operations while rehabilitation work is undertaken on other PATH tracks. The temporary track would cover column bases and footprint areas outside the existing PATH right-of-way during the construction period, but this track would be removed upon completion of the permanent tracks.

- ***Bathtub Walls*** (constructed pre-September 11) and Tiebacks (constructed post-September 11/temporary): All four of the slurry walls forming the "bathtub" would require some modification in order to ensure their continued structural function, which is to secure the "basement" of this portion of the WTC site from the high water table resulting from the site's proximity to the Hudson River.

  The Preferred Alternative includes the reinforcement of portions of the basement walls to ensure their structural integrity and to support future redevelopment of the WTC site, including the Permanent WTC PATH Terminal. A portion of the approximately 70 foot high west slurry wall, with tieback caps exposed, is proposed to remain visible and accessible to the public (a separate undertaking), and another portion of the west wall would be pierced (in a location away from the proposed exposed section) for the east-west pedestrian concourse below Route 9A. The remainder of the west wall would be protectively lined as part of the Preferred Alternative. PANYNJ would also reinforce portions of the east bathtub wall abutting NYCT's 1 and 9 line that were not previously reinforced. If other development on the WTC site does not move forward according to current schedules or plans, it may also be necessary to reinforce portions of the north bathtub wall east of Freedom Tower and portions of the south bathtub wall above the existing PATH substation. Where liners are installed, existing tieback caps would remain although their projections would be subsumed within the concrete of the liners.

- ***Recovery and Construction Ramp*** (constructed post-September 11/temporary): The support foundation for the ramp would be relocated to allow for construction of a temporary track. The ramp would remain during early construction of the Preferred Alternative and would then be removed.

- ***North and South Tunnel Projections from West Wall*** (constructed pre-September 11): Structural modifications would be made to the projections to accommodate the temporary Track 6.
- ***H&M Remnants*** (constructed pre-September 11): The cast-iron ring tubes in the east slurry wall of the bathtub would be removed for construction of the Preferred Alternative. On the eastern portion of the WTC site, all or portions of the remnants of the former H&M Terminal building and its powerhouse would be removed to construct a north-south concourse for the Preferred Alternative. Other remnants of these tubes (under the Hudson River) would still remain in service.
- ***Other Vehicular Ramps*** (constructed pre-September 11): Several of these ramps would be removed or sealed off, as they would have no function under the Preferred Alternative. This would also accommodate construction of new pedestrian concourses.
- ***PATH Tracks and Substation*** (reconstructed post-September 11): The PATH tracks that are part of the temporary WTC PATH station, would remain but would be further modified for permanent operation and to install a switch to the temporary Track 6. The wiring at the existing substation, also installed as part of the temporary PATH facility, would be modified for the permanent operation.
- ***Existing WTC PATH Station Main Entrance and Concourse, Sidewalks, Fencing, Existing PATH Platforms/Mezzanine*** (constructed post-September 11/temporary): Portions of these elements would be removed for construction of a permanent entry facility, main transit hall, concourses, PATH mezzanine, and platform levels.
- ***Passageway to the NYCT WTC Subway Station (E-Train)*** (constructed pre-September 11): The passageway between the Terminal and the MTA/NYCT E Subway would be designed to incorporate the existing E Subway entrance in its current location. Certain elements and materials of this passageway, which were retained as part of the construction of the temporary station, would be preserved as part of the Preferred Alternative. However, it may be necessary to remove the doors during construction for their protection. They would be stored until they could be returned to the reconstructed passageway.
- ***Steel Beams in Cross Form*** (post-September 11): The "steel cross" was moved from the area of 6 WTC to its current location in the eastern portion of the WTC site near the intersection of Church and Cortlandt Streets for public viewing. The cross structure would be removed from this location to accommodate the new north-south pedestrian concourse construction at-grade. The steel beam in cross form would remain in the custody of PANYNJ pending its disposition in accordance with the rights of its respective owners.
- ***Plaza and Subway Access from Vesey Street*** (constructed pre-September 11): The structural remnants of this access from Vesey Street are not permanently stable or functional. However, construction of the Preferred Alternative would not directly impact these elements. Furthermore, as described in the Project's MOA, a Resource Plan would be prepared to include these structures with measures to protect them from potential indirect effects during the Terminal's construction.
- ***Cooling Water Pipes*** (constructed pre-September 11): The Preferred Alternative would have no impact on the cooling water pipes. However, sections of the existing cooling water pipes may be reconstructed or rerouted under a separate undertaking.

Historic Resources Outside the WTC Site

Sub-grade work associated with construction of the Preferred Alternative could affect historic resources located within 90 feet of the Project Site. Based on the analysis described in Chapter 10, "Noise and Vibration," construction of the Terminal may cause damage to these buildings from ground-borne vibrations and dewatering. Specifically, historic buildings or sites located within 90 feet of the Project Site include the Barclay-Vesey Building at 140 West Street, St. Paul's Chapel and Graveyard, the former East River Savings Bank at 26 Cortlandt Street, the Beard Building at 125 Cedar Street, and 114-118 Liberty Street. (Other historic resources are more distant from the Project Site and are not within the area that is expected to be affected by construction.)

These potential adverse effects would be mitigated by Construction Protection Plan(s), the protocol and stipulations of which have been addressed in the MOA (see Appendix B).

OPENING YEAR (2009)

FUTURE COMMON TO ALL ALTERNATIVES

Portions of the WTC Memorial and Redevelopment plan would be complete while other construction activity would continue. The Greenwich Street view corridor and possibly the street itself will be open north into Tribeca. In addition, reconstruction of Route 9A between West Thames and Chambers Streets would be complete. As described earlier, the Programmatic Agreements executed by LMDC and NYSDOT for their respective undertakings will continue to guide the design and construction of those projects with respect to potential impacts to historic resources. In BPC, Site 26 is slated for commercial development and may be opened. The Fulton Street Transit Center would be open, east of the Permanent WTC PATH Terminal.

NO ACTION ALTERNATIVE

Project Site

In 2009 without the Preferred Alternative, the temporary WTC PATH station would remain in service. Some construction activities associated with the WTC Memorial and Redevelopment Plan would continue.

Area of Potential Effect

It is not expected that this alternative would have any adverse effects on historic resources.

PREFERRED ALTERNATIVE

Project Site

The tracks, platforms, mezzanine, concourses, and street-level terminal building would be located on the WTC site. The terminal building would provide street-level access to the WTC site and Greenwich and Church Streets. The terminal building would be designed by Santiago Calatrava, an award-winning architect, artist and engineer. His works include the Olympic Sports Complex (Athens, 2001), the Milwaukee Art Museum (1994), several railway stations (Liege, 1996; Lisbon, 1993; and Alameda, 1991), and several bridges (Buenos Aires, 1998; Orleans, 1996; Venice, 1996; Bilbao, 1994; and Merida, 1988). The terminal would be modern in design and would be lower in height than the WTC buildings adjacent to it on the south and to

the north of it across Fulton Street. Underground pedestrian concourses connecting to other transit systems would also be complete by 2009.

Two ventilation structures would be within the Route 9A median. As these locations have no potential for archaeological sensitivity, construction of the ventilation structures would have no adverse effect on archaeological resources.

Area of Potential Effect

In terms of contextual or visual effects, the APE is developed with a mix of historic and modern structures that range in height from one to 60 stories. The size and architectural styles of these buildings vary greatly, reflecting the architectural styles of the eras in which they were designed and constructed. The APE is composed of historic structures near more modern structures, where many streets contain a mixture of historic structures in immediate proximity to contemporary glass and metal structures. The historic context of the APE was dramatically changed during the 1960s with the construction of the WTC. Redevelopment of the WTC site, which will be underway by 2009 independent of the Preferred Alternative, will again introduce modern skyscrapers to the immediate area. By 2009, Freedom Tower will be completed on the northwest quadrant of the WTC site and will be a tall, modern structure. In contrast, the Terminal planned under the Preferred Alternative would be of a lower height and scale than existing buildings in the immediate area, as well as adjacent structures completed and/or development on the WTC site.

It is anticipated that Calatrava's design for the proposed terminal building would be constructed of glass, steel and concrete, and would be similar to the materials used in Wedge of Light Plaza that would be constructed along Church Street as part of the WTC Memorial and Redevelopment Plan. It would also be in keeping with modern structures that exist in the study area, such as the Winter Garden and other buildings in the WFC and BPC. It would continue the tradition in the downtown area where technologically advanced modern buildings have been constructed near older, historic structures, thus continuing the existing trend of modern buildings juxtaposed against the historic fabric of Lower Manhattan. It is also anticipated that Calatrava's design would be modern and unique to the area, and that the new terminal may become an important architectural resource. It is expected that the proposed terminal building would be an improvement over current conditions and would introduce an important architectural resource to the APE.

The proposed development would not alter the historic context of the surrounding area, as this context was significantly altered with the completion of the WTC and subsequent modern office buildings that were (and will be) erected in the APE.

It is not anticipated that the street level access to the below-grade pedestrian concourse at the WFC would have any contextual or visual effects on historic resources. Several street level subway entrances already exist within the APE, in close proximity to historic resources. It is anticipated that this entrance would be similar to other subway entrances located throughout the APE.

It is not anticipated that the vent structures would have any contextual or visual effects on historic resources. The vent structures within the Route 9A median would be long and slender in massing and would stand 40 feet tall. It is anticipated that the vent structures would be clad in reflective material that would be in keeping with modern materials used on buildings in the immediate area. This reflective material would also help the vent structures to blend in with their natural surroundings. Surrounding each vent structure, trees would be planted in the median as part of greening improvements to Route 9A. It is anticipated that these trees would be 35 feet in

height within five years, thus obscuring views of the vent structures from historic resources located in the APE. Although the vent structures would be located west of the WTC site, it is not anticipated that these structures would affect the WTC site, as they would not block views towards the site and tall trees would obscure views of these structures from the WTC site. Overall, it is not anticipated that the vent structures would have any adverse contextual or visual effects on historic resources, as they would be consistent with modern buildings in the surrounding area and would be obscured by tall trees that would be planted in the Route 9A median.

DESIGN YEAR (2025)

FUTURE COMMON TO ALL ALTERNATIVES

By 2025, it is assumed that the full program for the WTC site would be developed, with the completion of the three towers on the east side of the WTC site and a fifth tower south of Liberty Street. A 65-story office building (Tower 2) and a 25-story hotel would be completed in the northeast quadrant. In the southeast quadrant, a 62-story office building (Tower 3) and a 58-story office building (Tower 4) would be completed. A 57-story office building (Tower 5) would be completed south of Liberty Street. Two office towers will also be developed at 130 and 140 Liberty Street.

NO ACTION ALTERNATIVE

Project Site

In 2025 absent the Preferred Alternative, it is assumed that PATH service would no longer operate at the Project Site. The temporary WTC PATH station would still be located on the Project Site, unless removed by a separate undertaking, but would not be operational. Construction activities associated with the WTC Memorial and Redevelopment Plan would be complete, and it is anticipated that there would be increased pedestrian traffic on the Project Site.

Area of Potential Effect

It is not expected that this alternative would have any adverse effects on historic resources.

PREFERRED ALTERNATIVE

Project Site

All work associated with the Preferred Alternative would have been completed for a period of 16 years after its initial operation. It is anticipated that there would be increased pedestrian traffic on the Project Site as a result of the Preferred Alternative.

Area of Potential Effect

In 2025, it is anticipated that there would be increased pedestrian traffic in the area immediately surrounding the Project Site. However, this would not change the character of historic resources located in the APE as the context of the Project Site and surrounding area has historically been defined by transportation uses, first with the H&M Terminal, then with the pre-September 11, 2001 WTC PATH Terminal and currently with the temporary WTC PATH station. Thus, the APE has been characterized by transportation uses and pedestrian traffic and it is not anticipated that an increase in pedestrian traffic would have an adverse effect on historic resources.

E. MITIGATION

PROJECT-SPECIFIC COMMITMENTS

As described in Chapter 18, "Agency Coordination, Process, and Public Participation," FTA and PANYNJ have solicited and fully considered comments from consulting parties and other interested members of the public regarding measures to minimize or mitigate adverse effects of the construction and operation of the Permanent WTC PATH Terminal. The agreed upon measures are contained in an MOA that has been executed among FTA, SHPO, ACHP, and PANYNJ (see Appendix B). This MOA for the Permanent WTC PATH Terminal has been prepared pursuant to the finding that the Preferred Alternative would have adverse effects on the WTC site and the Hudson River Bulkhead. The MOA also addresses the potential effects of the Preferred Alternative on as yet undetermined archaeological resources on the WTC site and on off-site historic resources during construction.

WTC SITE

The executed MOA provides for specific measures to mitigate impacts on the remaining remnants and structures on the WTC site. Specifically, it includes measures pertaining to the tower perimeter column bases and footprint areas, the passageway to the NYCT E WTC subway station, the steel beam in cross form, and the east and west slurry walls. Furthermore, the MOA has general provisions for the documentation of the WTC site, and protection of remaining remnants and structures during construction. The MOA also provides stipulations for the treatment of cumulative effects, which is described in Chapter 15, "Cumulative Effects," of this FEIS.

WTC Site Documentation

As stated in the MOA, PANYNJ would document the WTC site and its historic features to Level II standards of the Historic American Buildings Survey/Historic American Engineering Record (HABS/HAER) prior to the removal or alteration of any historic features from the WTC site in connection with the undertaking of the Permanent WTC PATH Terminal. This documentation would consist of large-format, black-and-white photography of the site and its historic features as they currently exist; large-format photographic reproduction of selected existing drawings of current conditions and of pre-September 11, 2001 conditions; and a written history and description of the site and its historic features using information previously generated for the Coordinated DOE for the WTC site as well as the Permanent WTC PATH Terminal's DEIS and FEIS. PANYNJ would coordinate the photographic effort with the photographic efforts related to LMDC's fulfillment of Stipulation 1 as set forth in the April 22, 2004 Programmatic Agreement among the ACHP, LMDC, and SHPO for the WTC Memorial and Redevelopment Plan.

PANYNJ would consult with SHPO and HABS/HAER to determine whether particular features warrant measured drawings, and any such drawings would be prepared by an individual with demonstrated experience in the preparation of measured drawings to HABS/HAER standards.

The completed documentation would be submitted to SHPO and HABS/HAER for consideration. The large-format photographs prepared to HABS/HAER standards would consist of the views itemized in Exhibit H, "Schedule of Photographs" of the Project's MOA (see Appendix B).

Tower Perimeter Column Bases

Up to a total of 5 column bases in the North Tower and up to a total of 3 column bases in the South Tower may be temporarily or permanently removed to construct PATH Platform D. Where Platform D would intersect the northeast corner of the North Tower footprint, the platform would be clear of vertical obstructions and architectural treatments would be used to symbolically represent the location of the footprint. A minimum of 5 to a maximum of 7 column bases of the east column line of the North Tower would be visible from Platform D. The viewing area would consist of a glass wall tilted inward from the platform combined with a mirrored wall to the west to provide a view of the column bases from this area of the platform. Appropriate signage, graphics, and lighting would complete the viewing area.

The locations of column remnants of the South Tower that may be removed or permanently obscured by PATH platforms B, C, and D would be symbolically represented on these platforms through architectural treatments that define and differentiate the portions of the infrastructure that are within the Tower footprint areas. These treatments may include color differentiation, texture differentiation, symbolic representation of Tower perimeter column remnants, and/or an emblematic marker designating the location of the historic resource.

In addition to the column bases described above, up to 4 column bases in the North Tower could be temporarily removed by work to install other Project structures and infrastructure. Of the 4 column bases that could be affected by the Project foundation, those column bases that remain in situ undisturbed or are temporarily removed and returned to their original locations would be accessible following the completion of these foundations.

Removing column bases, on either a temporary or permanent basis, would be considered only after practical engineering design options pursuant to Stipulations I.B., 2a and 2b, to preserve column bases in place have been exhausted. Column bases that are removed would be returned to their original locations if practical engineering design permits. Permanent removal of column bases would only take place as a last resort, and these column bases would be removed and stored in accordance with the stipulations of the MOA.

The east-west pedestrian concourse to the World Financial Center would be designed and built in a manner that avoids the column remnants projecting above the concrete slab that outline the north perimeter of the North Tower and places this corridor at least five (5) feet outside the North Tower footprint as measured from the center line of each projecting column base to the face of the nearest structural support wall.

The temporary PATH track (in addition to the existing 5 tracks) and associated ballast that would be installed on a temporary basis during construction of the Project tracks and platforms and would be removed upon completion of the permanent tracks and platforms to re-expose the North and South Tower perimeter column remnants and portions of the North and South Tower footprints that may be covered by the temporary track and ballast.

The construction fill currently on the footprints has been temporarily removed for the purposes of documentation of the footprints pursuant to Stipulation I.A. of the MOA, and would be replaced with clean rounded gravel as required after the documentation in order to protect the footprints and column remnants from ongoing construction. Further treatments may be specified in the Project's Resource Protection Plan.

Passageway to the NYCT Subway Station (E Train)

The new pedestrian connection between the Permanent WTC PATH Terminal and the MTA/NYCT WTC E Subway Station would incorporate the existing E subway entrance, in its current location, in a manner that retains existing materials and features of this entrance, including, but not limited to, the handrails, the travertine flooring, the steps and doors separating the E train from the pedestrian connection, and overhead signage, to the extent possible and in accordance with current building codes and Americans with Disabilities Act requirements. The design would include, at a minimum, a plaque identifying the historic features of the E subway entrance. During construction of the new pedestrian connection between the Permanent WTC PATH Terminal and the E Subway Entrance, doors may need to be carefully removed and stored until they can be reinstalled within the new connection.

East and West Slurry Walls

The design for the Preferred Alternative would provide visibility from within the Terminal to a portion of the east or west slurry wall if the following criteria are met: the condition of the slurry wall evokes the image now understood to represent the historic nature of the wall (e.g. tiebacks are part of the area to be exposed, tiebacks project beyond the re-stabilized slurry wall); the exposure provided would enable a view of the slurry wall that is clear, recognizable, and respectful of the slurry wall; and the exposure would not pose a safety hazard to the public from exposed finishes of the wall or its components. The design for the east-west pedestrian concourse shall include a location from which the members of the public may view a plaque and photograph of the west slurry wall.

Steel Beams in Cross Form

PANYNJ would relocate the steel column and crossbeam mounted on a concrete pedestal and currently situated within the WTC site near Church Street in accordance with Stipulation VI of the MOA (see Appendix B). The object would remain in the custody and control of PANYNJ pending final disposition of these artifacts in accordance with the rights of the respective owners.

Resource Protection Plan for the WTC Site

PANYNJ, in consultation with SHPO and in coordination with LMDC and MTA/NYCT, as appropriate, shall develop a WTC Resource Protection Plan for the Permanent WTC PATH Terminal. The plan would be prepared to protect elements of the WTC site that are to remain in situ from inadvertent damage during the Terminal's construction. It would detail the Project's construction procedures and other construction plans for the site. It would provide for an inspection and reporting of the existing condition of elements, establish protection procedures, establish a monitoring program, and establish methods and materials to be used for any repairs. A historic architect, who meets the Secretary of the Interior's professional qualifications standards (48 FR 44716) in historic preservation, would be part of the design/construction team and would have the opportunity to review design drawing and specifications prior to construction. The plan would empower the Project's historic architect in consultation with the Chief Engineer of PANYNJ to issue "stop work" orders to prevent any unanticipated damage to historic properties. Recommencement of work would only be permitted once the Chief Engineer of PANYNJ and the historic architect are assured that appropriate modifications have been made to construction techniques to assure that no further damage would occur.

PANYNJ will furnish copies of the Plan to SHPO, ACHP, NPS, and the Section 106 consulting parties for review and comment prior to its implementation.

ARCHAEOLOGICAL TREATMENT PLANS

The executed MOA includes the process to address the Preferred Alternative's impacts on the Hudson River Bulkhead and its potential impacts to as yet determined archaeological resources that may be located within the eastern potion of the WTC site. Because the Hudson River Bulkhead is also located within the APE for the Route 9A Project, PANYNJ would coordinate its treatment plan with NYSDOT. Similarly because the potential archaeological resources within the WTC site are also located within the APE for the WTC Memorial and Redevelopment Plan, PANYNJ would coordinate its treatment plan, if necessary, with LMDC.

In consultation with SHPO, and, as appropriate, NYSDOT, PANYNJ would develop and implement a plan to locate and identify intact portions of the Hudson River Bulkhead that would be affected by construction of the Permanent WTC PATH Terminal's east-west pedestrian connection. In the event that the intact portions of the Hudson River Bulkhead are identified, PANYNJ would, in consultation with the SHPO and NYSDOT, prepare a treatment plan for those portions of the Hudson River Bulkhead to be affected by the Project. The plan would be submitted to SHPO and Section 106 consulting parties for their review and comment prior to implementation.

Prior to any Project-related subsurface disturbance at any of the locations that have been determined to be sensitive for historic archaeological resources, PANYNJ will, in consultation with the SHPO, and LMDC as appropriate identify and evaluate the National Register eligibility of any archaeological resources at these locations in accordance with 36 CFR 800.4.

In the event that FTA, in consultation with SHPO, determines that National Register-eligible archaeological resources will be adversely affected by construction of the Preferred Alternative, PANYNJ would, in consultation with FTA, SHPO, and LMDC as appropriate, and the Section 106 consulting parties, develop and implement an Archaeological Resource Treatment Plan for the Project. The Archaeological Resource Treatment Plan and documentation will adhere to the standards established by the Secretary of the Interior's Standards and Guidelines for Archaeology and Historic Preservation (48 FR 44716), including the standards therein for professional qualifications. The plan will be submitted to SHPO and Section 106 consulting parties for their review and comment prior to implementation.

CONSTRUCTION PROTECTION PLANS

The MOA includes protocols for developing and implementing a CPP to avoid, minimize, or mitigate the project's potential construction-period vibration impacts on the Barcley-Vesey Building, Former East River Savings Bank, the Beard Building, 114-118 Liberty Street, and St. Paul's Chapel and Graveyard.

PANYNJ, in consultation with SHPO and Section 106 consulting parties, and in coordination with LMDC, NYSDOT, and MTA/NYCT, where appropriate, shall develop a Construction Protection Plan (CPP) for the Preferred Alternative. The CPP would set forth measures for the protection and avoidance of structural and architectural damage for these historic properties. The CPP would be based on requirements in the "New York City Department of Buildings Technical Policy and Procedure Notice (PPN) #10/88" regarding procedures for the avoidance of damage to historic structures resulting from adjacent construction. The PPN defines adjacent historic structures as being contiguous or within a lateral disturbance of 90 feet from a lot under development or alteration.

The CPP would describe in detail the construction procedures of the Preferred Alternative, as well as the construction procedures associated with other projects under construction in the vicinity of each of these historic properties. It would also provide for the inspecting and reporting of existing conditions at these properties, establish protection procedures, establish a monitoring program to measure vertical and lateral movement and vibration, establish and monitor construction methods to limit vibration; and establish methods and materials to be used for any repairs. The plan shall also specify the implementation of special vibration protection measures to protect these historic properties from increased vibration levels associated with construction activities. The CPP would provide for a historical architect meeting the Secretary of Interior's Standards to supervise implementation of the CPP.

The CPP would empower the historical architect, in consultation with the Chief Engineer of PANYNJ to issue "stop work" orders to prevent any damage to historic properties, and any recommencement of work shall only be permitted at such time that the Chief Engineer and historical architect have assurance that the appropriate modifications have been made to the construction technique to assure that no damage would occur to historic properties.

ENVIRONMENTAL PERFORMANCE COMMITTMENTS

As described in Chapter 2, "Project Alternatives," and Chapter 3, "Construction Methods and Materials," PANYNJ, in cooperation with the sponsors of the other Lower Manhattan recovery projects, has developed Environmental Performance Commitments (EPCs) to protect historic resources during construction of the Preferred Alternative. Table 6-2 describes the EPCs that pertain to historic resources as well as current plans for their implementation.

Table 6-2
Environmental Performance Commitments

Commitment	Implementation Plan
Establish coordination among projects to avoid or minimize interruption in access to cultural and historic sites.	Access to cultural sites within the APE for the Preferred Alternative will be maintained, to the maximum extent feasible given public safety considerations, as part of the Preferred Alternative's Maintenance and Protection of Traffic (MPT) Plan. The TMP for all of the Lower Manhattan Recovery Projects will also coordinate access to cultural sites.
Initiate public information and involvement outreach with sensitivity to local cultural resources.	PANYNJ has coordinated with the Project's Section 106 consulting parties to develop and execute a Memorandum of Agreement pursuant to Section 106 of the National Historic Preservation Act. The executed Memorandum of Agreement includes stipulations for ongoing coordination and consultation as the Preferred Alternative's design and construction moves forward. Materials pertaining to the Project's effects on cultural resources will made available on the project's website in accordance with the stipulations of the executed Memorandum of Agreement.
Identify public information outlets that will receive and provide current information about access during construction.	This EPC will be implemented through the Lower Manhattan Construction Command Center pursuant to Governor Pataki's Executive Order.
Consult with SHPO and LPC regarding potentially impacted, culturally significant sites. Monitor noise and vibration during construction at such sites as appropriate.	PANYNJ has and will continue to coordinate with the ACHP, SHPO, LPC, and the Section 106 consulting parties pursuant to the stipulations of the executed Memorandum of Agreement. As specified in the executed Memorandum of Agreement, PANYNJ will consult with SHPO and LPC to develop construction protection plans to monitor fragile buildings within the Preferred Alternative's APE and to stipulate measures to avert impacts to these structures. As described in the executed Memorandum of Agreement, PANYNJ will coordinate its CPPs with LMDC, MTA/NYCT, and/or NYSDOT, as appropriate, for those structures that may be cumulatively affected by construction vibrations.

*

Chapter 7: Urban Design and Visual Resources

A. INTRODUCTION

Lower Manhattan is developed with a dense concentration of historic and modern buildings that range in size from small-scale, low-rise structures to large-scale, high-rise structures. They reflect a variety of architectural styles that have been built over the years as commerce in Lower Manhattan has flourished and expressed its success in built form. The streets and open spaces surrounding this rich collection of buildings provide unique views that are distinguished from the views of other cities.

For 30 years, the World Trade Center's (WTC) Twin Towers were the tallest elements of those views and readily identifiable from miles around. Prior to September 11, 2001 the WTC complex occupied a superblock site and had a strong presence on the urban design of the area. A WTC PATH Terminal was located at the WTC and was an important transportation hub for the area. Following the events of September 11, 2001 and the subsequent recovery efforts, the WTC site had lost its transportation hub as well as the other aspects of the WTC. Construction activities have continued on the site as part of various phases of recovery and stabilization and included the construction of the temporary WTC PATH station, which opened for public use in November 2003.

The Preferred Alternative would introduce a visually important terminal building to the study area and would contribute to the larger redevelopment of Lower Manhattan. The modern design of the new terminal would create a new gateway to Lower Manhattan and would re-establish the site as an important transportation center.

This chapter considers the impact of the Preferred Alternative on the urban design character and visual resources of the study area from nearby locations from which the project would be visible. The study area has been delineated as the area generally bounded by Barclay Street to the north, Cedar and Thames Streets to the south, Battery Park City (BPC) to the west and Broadway to the east (see Figure 7-1). This study area was developed to be consistent with the study area defined for Cultural Resources (see Chapter 6).

Urban design characteristics and visual resources create the "look" of a neighborhood—its physical appearance, including the size and shape of buildings, their arrangement on blocks, the street pattern, and noteworthy views that may give an area a distinctive character and contribute to its unique sense of place. Urban design characteristics of a neighborhood are composed of the various components in the buildings and streets of the area and include building bulk, use and height, block forms and street patterns, streetscape elements, and natural features. An area's visual resources are its unique or important public view corridors, vistas, or natural or built features. They include views from public and publicly accessible locations only.*

---

* As defined in the *City Environmental Quality Review* (CEQR) *Technical Manual*, page 3G-1.

B. METHODOLOGY

Three analysis years—2006 (construction year), 2009 (opening year), and 2025 (design year)—are considered. While the analysis is primarily based upon conditions that exist today at the Project Site and in the surrounding study area, a discussion of the study area prior to the events of September 11, 2001 is included in this chapter to provide an overall context for the analysis which follows. Anticipated changes in the urban design and visual resources of the study area that are expected to occur independently of the Preferred Alternative by each analysis year are identified and potential impacts associated with each of the Preferred Alternatives are assessed.

The analysis of potential impacts to urban design and visual resources was conducted using the guidance set forth in the 2001 *City Environmental Quality Review* (CEQR) *Technical Manual.* Once the study area was established, the urban design characteristics and significant visual resources were described. Field visits were conducted to obtain information about the urban design and visual resources located within the study area. The information gathered in the field was supplemented with data obtained from Sanborn maps. Once this information was gathered, an assessment was prepared, focusing on urban design elements and visual resources that could be impacted.

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

PRE-SEPTEMBER 11, 2001 BASELINE CONDITIONS

PROJECT SITE

Urban Design

Prior to September 11, 2001, the Project Site was occupied by a WTC PATH Terminal, which included a track and platform level, an associated mezzanine/fare-zone level, and sub-grade pedestrian connections to adjacent streets, subways, and the WTC. There were no above-ground features of the terminal, as it was accessed through the WTC buildings (see Figure 7-2).

Visual Resources and View Corridors

Prior to September 11, 2001, the Twin Towers were important visual resources. Buildings associated with the WTC blocked views across the Project Site from other portions of the study area.

STUDY AREA

Comprising important parts of Lower Manhattan, the study area prior to September 11, 2001, was densely developed with office buildings, a number of which have been converted to residential use in recent years. The discussion below focuses first on the study area's urban design—its basic layout and structures—and then describes its visual resources.

Urban Design

Natural Features, Street Patterns, and Block Shapes. The topography of the study area sloped slightly to the south and west. Street patterns were slightly irregular. Route 9A and Greenwich Street generally traveled in a north-south direction, while West Broadway, Church Street, and Broadway traveled in a northeast-southwest direction. As a result, the blocks west of West

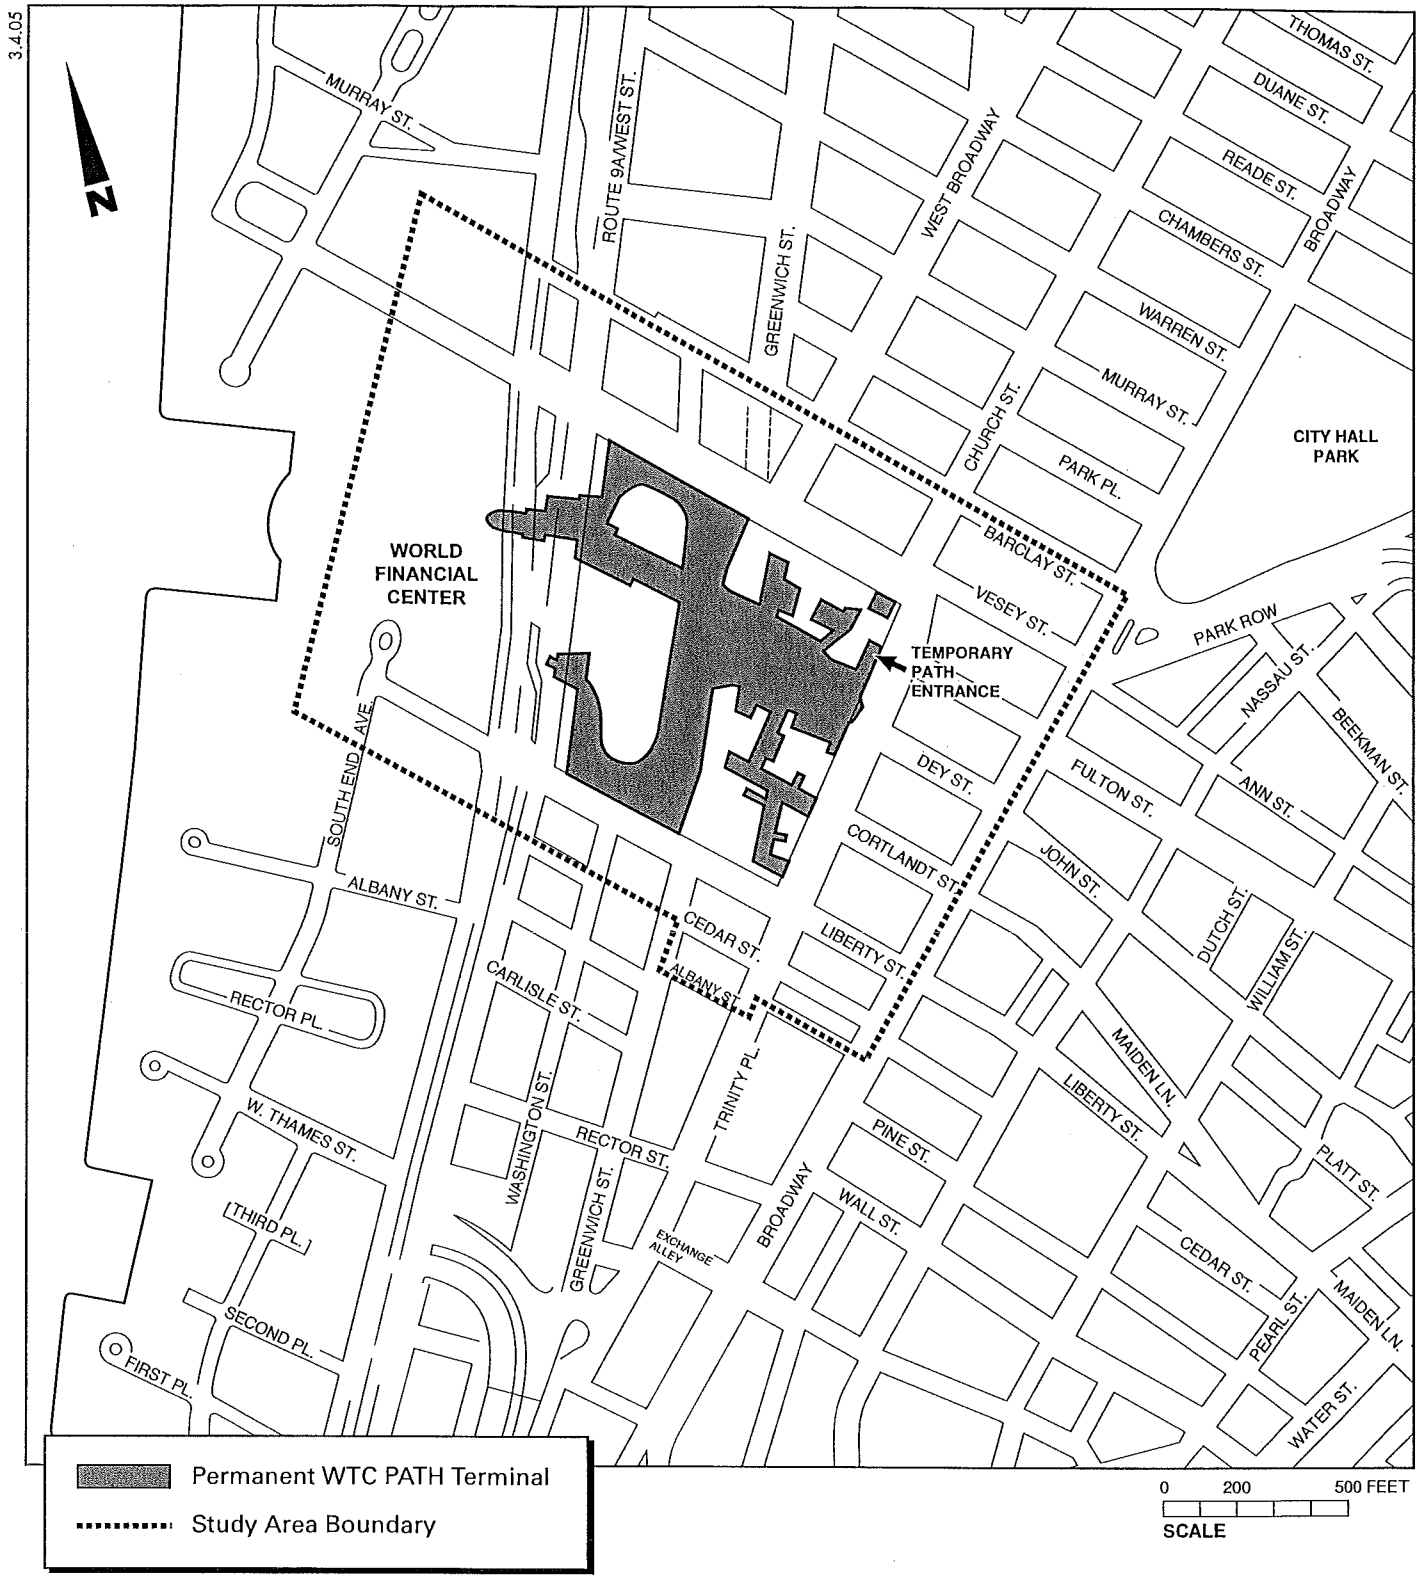

Figure 7-1

Urban Design and Visual Resources Study Area

Figure 7-2

Urban Design and Visual Resources Pre-September 11, 2001 Conditions

Broadway had irregular shapes. Route 9A, Broadway and Church Street were the primary roadways in the study area carrying multiple lanes of vehicular traffic.

Greenwich Street terminated at Barclay Street as Seven World Trade Center (7 WTC) occupied the entire area between Washington Street on the west and West Broadway on the east. West Broadway was open to Vesey Street where it ended at the WTC site. The WTC occupied a superblock site and had a strong impact on the street patterns and block shapes in the study area.

Large office buildings—including the Barclay-Vesey Building, the Federal Office Building/U.S. Post Office and One Liberty Plaza—occupied full blocks. St. Paul's Chapel, with its adjoining graveyard, also occupied a full block. Liberty Plaza occupied the full block bounded by Liberty and Cedar Street, Trinity Place and Broadway.

In BPC, there were no streets through the World Financial Center (WFC) between Liberty Street on the south and Vesey Street on the north. South End Avenue was the north-south roadway south of Liberty Street as was North End Avenue north of Vesey Street. Block shapes were not regular, and most structures were not built to the lot line.

Streetscape. The study area was urban in character, with streets flanked by concrete sidewalks. Most buildings extended to the lot line. Parked cars lined most streets. Various kinds of street furniture were found throughout study area, including fire hydrants, mailboxes, newsstands, lampposts and vendor carts. Most lampposts located along Route 9A were reproductions of historic lampposts, while others were of more modern design. Historic fire alarm call boxes were unique urban artifacts also found in the study area.

While still very urban in character, BPC was visually distinct from the rest of the study area. It was physically divided from the study area by Route 9A, the only multi-lane highway in the area. The WFC was set back from Route 9A's bikeway/walkway by a wide concrete sidewalk along the building front and a green lawn beyond that. Open space, both paved plazas and landscaped areas, was far more prevalent in BPC than elsewhere in the study area. BPC also had a great variety of attractive, well-designed street furniture, including benches, tables, and lampposts.

The streetscape on the north side of 7 WTC was the location of the wide truck ramp off Barclay Street that provided service access to the underground levels of the WTC. To reach this ramp, trucks were lined up on the west side of West Broadway for several blocks. The WTC as well as the wide and busy Route 9A roadway separated the WFC from the streets of Lower Manhattan. Two twelve-foot-tall vent structures for the WTC PATH Terminal were also located in the Route 9A median, opposite the WTC. Liberty and Vesey Streets were both open, providing vehicular access.

Building Uses, Shapes, and Forms. Prior to September 11, 2001, six buildings were located on the WTC superblock, most notably the 110-story Twin Towers (One and Two World Trade Center). These 1,350-foot-tall aluminum-clad skyscrapers (excluding the 345.1-foot antenna) were the tallest buildings in New York and had a dominating presence on the New York City skyline (see Figure 7-3). The Twin Towers were important visual resources due to their height and modern design. Other buildings on the site were more modest in scale. These included a 22-story hotel (Three World Trade Center), two nine-story buildings (Four and Five World Trade Center), and the eight-story U.S. Customs House (Six World Trade Center). These buildings were situated around the Austin J. Tobin Plaza, which was decorated with several sculptures. An enclosed pedestrian bridge over Route 9A connected the WTC with the Winter Garden in the WFC and was wider than the bridge that still crosses Route 9A at Liberty Street. Another shorter

pedestrian bridge crossed over Vesey Street from the WTC plaza to 7 WTC. The building at 7 WTC occupied the full block between Barclay, Vesey and Washington Streets and West Broadway.

A 39-story office building stood at 130 Liberty Street. Located directly across Liberty Street from 2 WTC, it had a plaza with a fountain.

The remainder of the study area was developed with a mix of historic and modern, low- and high-rise buildings. Almost all the buildings were originally constructed as office buildings, although several had been converted to residential use. Three churches were located in the study area—St. Paul's Chapel, St. Peter's Roman Catholic Church and St. Nicholas Greek Orthodox Church. Aside from the WTC, buildings in the study area ranged in height from two to 54 stories. Several tall office buildings were located in the study area and included the Barclay-Vesey Building with its dramatic setbacks, the Transportation Building at 225 Broadway, the former AT&T Company Building at 195 Broadway and One Liberty Plaza. Most buildings were built to the lot line, except for One Liberty Plaza, which was set back from its lot line and was surrounded by a plaza.

BPC was primarily developed with modern high-rise office and residential buildings. The WFC was a group of office towers clad in pink granite. They varied in height from 33 to 51 stories. Each structure was designed with a different geometric form at its roofline—mastaba, dome, pyramid, and stepped pyramid. The residential buildings west and south of the WFC varied in height from four to 28 stories.

Visual Resources and View Corridors

Prior to September 11, 2001, the Twin Towers were considered important visual features for the study area. The Austin J. Tobin Plaza and the plaza area along Church Street were visual and urban design amenities.

Despite its amenities, the WTC blocked view corridors. It cut off views north and south on Greenwich and Washington Streets, views south on West Broadway, and views west on Fulton, Dey, and Cortlandt Streets. The building at 130 Liberty Street blocked views east and west on Cedar Street.

7 WTC blocked views of the east side of the Art Deco Barclay-Vesey Building. Views from the south of the Barclay-Vesey Building were limited by 6 WTC and 1 WTC. 7 WTC blocked views south on Greenwich Street and views south on West Broadway ended at 5 WTC. A shorter structure and set back from the street, 5 WTC allowed more light up West Broadway than 7 WTC allowed up Greenwich Street.

Broadway, Church Street and Route 9A provided long north-south view corridors; however, the view corridor along Route 9A was partially blocked by the pedestrian bridges above the highway at Liberty and Vesey Streets. Views west on Barclay, Vesey, Liberty and Cedar Streets continued to BPC, while views east on these streets continued uninterrupted along narrow street corridors. The view corridors north along Washington and Greenwich Streets were blocked by 2 WTC and 4 WTC. In addition, the view east and west on Cedar Street was blocked by 130 Liberty Street—a building with dark glass windows that towered over the narrow streets to the east, south, and west of it.

In BPC, the buildings of the WFC were designed to harmonize with the size and design of the Twin Towers (see Figure 7-3). In views of Manhattan from the Hudson River or New Jersey, the WFC buildings stepped up the height of the built environment toward the WTC towers. On the

2.23.04

Source: PANYNJ

Figure 7-3

Urban Design and Visual Resources Pre-September 11, 2001 Conditions

other hand, because of the WTC the whole façade of the WFC along Route 9A could only be seen at an oblique angle. It was also not possible to see St. Paul's Chapel and the East River Savings Bank from the WFC prior to September 11, 2001.

Historic office buildings are frequently among the important visual resources of Lower Manhattan (see Chapter 6, "Cultural Resources"). Due to their heights, distinctive forms and decorative features, the Art Deco Barclay-Vesey Building (140 West Street/Route 9A), the neo-Gothic Woolworth Building (233 Broadway), the neo-Gothic building at 90 West Street, the Beaux Arts Equitable Building (120 Broadway) and the Art Deco Irving Trust Company Building (1 Wall Street) were unique visual resources that could be seen from throughout the study area.

Trinity Church was an important visual resource that was visible from the southern portion of the study area. Set between its graveyard and a small yard area, it was a relatively small neo-Gothic structure located at the head of Wall Street. Similarly, St. Paul's Chapel, opposite the northeast corner of the Project Site, was a visual resource along with its graveyard and large trees. The steeples of both churches were visible from blocks away, and the juxtaposition of their steeples against high-rise buildings, both sleek modern and more ornate older ones, was a defining feature of Lower Manhattan.

Another visual resource was Liberty Plaza. It was a paved full block with eight metal benches; a life-sized sculpture of a man with a briefcase and umbrella sat on one. Across the plaza there were views of the WTC but not the WFC. On Cortlandt, Dey, and Fulton Streets, the structures of the WTC blocked views west. Looking west on Cortlandt Street, 4 WTC was in front of 2 WTC. The view west across Fulton Street was to 5 WTC.

The modern granite-clad structures of the WFC and the glass walls of the Winter Garden were visible from Route 9A and adjoining side streets. While very attractive, the most important visual resources of BPC were the Hudson River and the many varied open spaces of BPC.

CHANGES IN THE AFFECTED ENVIRONMENT SINCE SEPTEMBER 11, 2001

This section provides a detailed description of urban design characteristics and visual resources in the study area which have changed since September 11, 2001. These differences are largely concentrated on the Project Site, the WTC site and the immediate area. This section highlights changes in urban design and visual resources which occurred as a direct result of the terrorist attacks along with any other changes which have occurred.

PROJECT SITE

Urban Design

The attacks of September 11, 2001 destroyed the WTC PATH Terminal along with the Twin Towers and the rest of the WTC. Today, the temporary WTC PATH station, which opened in November 2003, is located at the northeast portion of the Project Site (see Figure 7-4). The tracks of the temporary WTC PATH station curve around the south end of the bathtub, passing into the new structure of the temporary station. The temporary WTC PATH station's mezzanine level, station platforms, and rail tracks are located on the western portion of the site. The New York City Transit (NYCT) 1 and 9 subway line also bisects the Project Site. Additionally, a wide area along the east side of the Project Site is paved with concrete. The entrance to the temporary WTC PATH station is located here opposite Fulton Street. Sidewalk viewing areas are located along Church Street south of the WTC PATH entrance and on Liberty Street.

Portions of the former Hudson & Manhattan (H&M) Terminal exist on site; however, these portions are below grade and are not visible from street level. Damaged portions of the tunnels that traveled under the Hudson River—known as the Hudson Tubes—are located in the east wall. Only the south tube is visible (see Figure 7-4). Aside from the viewing areas and the temporary WTC PATH station, the remainder of the Project Site remains undeveloped and is fenced off and not accessible to the public (see Figure 7-5).

Visual Resources and View Corridors

On the Project Site at Fulton Street, the canopy of the temporary WTC PATH station has a sculptural form, with two wings rising from a central truss supported on two vertical trusses (see Figure 7-4). The fence, which stands along the public viewing area, allows visitors to see through it to the WTC site. The Port Authority of New York and New Jersey (PANYNJ) has posted informational boards telling the history of the site and high-rise buildings in Lower Manhattan.

As no other structures exist on the Project Site, the site is open and more sunlight reaches the Project Site and surrounding streets. View corridors are open across the site to other portions of the study area.

STUDY AREA

Urban Design

Natural Features, Street Patterns, and Block Shapes. Following the events of September 11, 2001, street patterns and block shapes changed slightly in the study area. The area south of Barclay Street and west of Greenwich Street is now closed to traffic by fencing and construction activity at 7 WTC. Greenwich Street, at least as a view corridor, is being reopened to Vesey Street by the new configuration of 7 WTC. Aside from the temporary WTC PATH station, the superblock of the WTC remains an undeveloped lot.

Many street segments were closed after the terrorist attacks and for the recovery activities. Closed streets include portions of Barclay, Vesey, Liberty and Cedar Streets, and the northern portions of Washington and Greenwich Streets.

Streetscape. Today, much of the streetscape surrounding the WTC site is dominated by construction. Otherwise, streetscape features in the study area are generally unchanged.

Building Uses, Shapes, and Forms. St. Nicholas Greek Orthodox Church, located south of the WTC site, was destroyed as a result of the events of September 11, 2001. The large block south of the WTC, bounded by Liberty, Greenwich, Albany, and Washington Streets, is occupied by a vacant office building at 130 Liberty Street. Its north façade (facing the WTC) was severely damaged in the attacks of September 11, 2001, and its two-level plaza was completely destroyed. The plaza area has been excavated, leaving a large hole in the ground surrounded mostly by a high construction wall. The large size of its lot, as well as the damaged and abandoned condition of the building, creates a strong presence on the adjoining streets.

Visual Resources and View Corridors

The WTC site in its current condition has opened view corridors to the north, south, west, and east (see Figure 7-6). The openness allows visual resources located in the study area to be seen from and across the WTC site. The Barclay-Vesey Building and the Federal Office Building/U.S. Post Office are now visible in views north, from south of the site. From locations

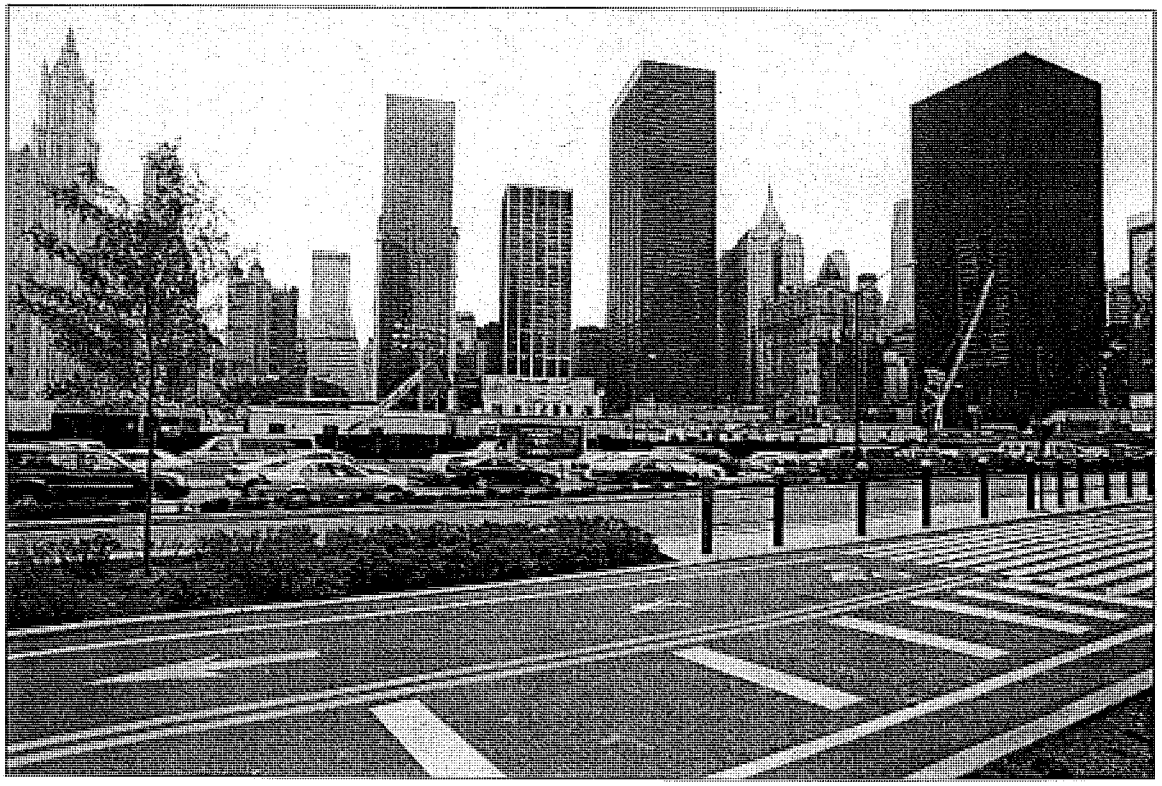
View west across the WTC site



View southeast across the WTC site

Figure 7-6

Urban Design and Visual Resources
Post-September 11, 2001 (Current) Conditions

west of the site, views of St. Paul's Chapel and the East River Savings Bank are available. From east of the site, views of the modern office towers of the WFC as well as views toward the Hudson River are available. Due to the undeveloped condition of the WTC site, the streets and buildings immediately surrounding it receive additional light.

Views west on Barclay, Vesey, Liberty and Cedar Streets are partially blocked by construction activity. Liberty Plaza was damaged on September 11, 2001 and has been partially restored. It remains a full-block open space with benches, planters, and lighting.

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

This section describes conditions that are or would be expected to exist under the project alternatives for three analysis scenarios (construction period, opening year, and design year).

CONSTRUCTION PERIOD (2006)

FUTURE COMMON TO ALL ALTERNATIVES

Initial reconstruction activities associated with the WTC Memorial and Redevelopment Plan would be taking place. St. Nicholas Church is expected to be reconstructed south of the WTC site by 2006.

Both the Barclay-Vesey Building and the Federal Office Building/U.S. Post Office, north of the Project Site, will be repaired, renovated, and reopened. Between these two buildings, 7 WTC will be complete along with its triangular open space on the north side of Vesey Street. A residential building is expected to be complete along Barclay Street, between Broadway and Church Street. The proposed building is expected to be taller than the adjacent small-scale buildings. In addition, reconstruction of Route 9A between West Thames and Chambers Streets will be taking place.

NO ACTION ALTERNATIVE

Project Site

Under the No Action Alternative, the temporary WTC PATH station would remain in service. Construction activities associated with the WTC Memorial and Redevelopment Plan would be occurring on site.

Study Area

It is not expected that this alternative would have any adverse impact to urban design features or visual resources.

PREFERRED ALTERNATIVE

Project Site

Construction of the Preferred Alternative would begin in 2005 concurrent with other sub-grade work for the proposed redevelopment of the WTC site. Components of the terminal, including the platforms, mezzanine, and certain pedestrian connections, would be completed by the end of 2006.

Study Area

It is not anticipated that this alternative would have any impact on natural features, street patterns, or block shapes in the study area, as none of these features would be altered. Construction activities associated with this alternative may temporarily impact streetscape features. As all work would take place below grade and there would be no above-ground features of this alternative completed by 2006, there is no anticipated adverse impact to building uses, shapes, and forms in the study area. Although there would be some above-grade construction activities as well as potential staging areas associated with this alternative, these construction activities would be temporary. As these construction activities would be temporary and would not have a permanent visual impact on the study area, it is not anticipated that there would be an adverse impact to visual resources and view corridors in the study area.

OPENING YEAR (2009)

FUTURE COMMON TO ALL ALTERNATIVES

Portions of the WTC Memorial and Redevelopment Plan would be complete while other construction activity would continue. The Greenwich Street view corridor and possibly the street itself will be open north into Tribeca. In addition, reconstruction of Route 9A between West Thames and Chambers Streets would be complete. In BPC, Site 26 is slated for commercial development. The Fulton Street Transit Center would be open, east of the Project Site.

NO ACTION ALTERNATIVE

Project Site

In 2009 without the Preferred Alternative, it is assumed that the temporary WTC PATH station would remain in service. Some construction activities associated with the WTC Memorial and Redevelopment Plan would continue while some would be complete on site.

Study Area

It is not expected that this alternative would have any adverse impact to urban design features or visual resources.

PREFERRED ALTERNATIVE

Project Site

The remaining portions of the Preferred Alternative would be completed in phases from 2007 to 2009. The terminal building would be located on the WTC site south of Fulton Street between Greenwich and Church Streets.

The terminal building would provide street-level access to the WTC site and Greenwich and Church Streets. It would be modern in design and would be lower in height than the WTC buildings adjacent to it on the south and to the north of it across Fulton Street. The terminal building would be designed by Santiago Calatrava, an award-winning architect, artist, and engineer. His works include the Olympic Sports Complex (Athens, 2001), the Milwaukee Art Museum (1994), several railway stations (Liege, 1996; Lisbon, 1993; and Alameda, 1991), and several bridges (Buenos Aires, 1998; Orleans, 1996; Venice, 1996; Bilbao, 1994; and Merida, 1988).

Calatrava's modern design for the terminal would incorporate two wing-like canopies that would run the length of the glass and steel shell of the terminal concourse (see Figures 7-7 and 7-8). These wings would be approximately 100 feet high and could pivot aside to create an opening to the sky along the main axis of the terminal. The terminal's design would complement the modern structures planned for the WTC site, such as Freedom Tower and Wedge of Light Plaza. The terminal would likely become an important visual resource for Lower Manhattan, and would create a grand point of entry for the new transportation center.

Underground pedestrian concourses connecting to New York City subways would also be complete by 2009. An above-ground entrance to the concourse would be located next to the World Financial Center. The Terminal would also include certain ancillary facilities and systems, including mechanical, ventilation, communications, and security.

In addition, two vent structures would be located in the Route 9A median, west of the WTC site. Both the north vent and the south vent would be of a long and slender massing and would stand 40 feet tall. It is anticipated that the structures would be clad in reflective material, in keeping with modern material used on buildings in the immediate area.

Study Area

In 2009, it is not anticipated that this alternative would have any impact on natural features, street patterns, or block shapes in the study area, as none of these features would be altered. It is not anticipated that there would be an adverse impact on streetscape features since existing elements would not be altered by the proposed development. The Project Site is expected to be developed with streetscape elements that would be in keeping with those found throughout the study area. Although the entrance to the temporary WTC PATH station would be replaced by the new entrance to the Permanent WTC PATH Terminal, it is expected that the new entrance would be developed with streetscape elements that would be in keeping with those found in the study area and would be an improvement over current conditions.

It is anticipated that Calatrava's design for the proposed terminal building would be constructed of glass, steel and concrete, and would be similar to the materials used in Wedge of Light Plaza that would be constructed along Church Street as part of the WTC Memorial and Redevelopment Plan. It would also be in keeping with modern structures that exist in the study area, such as the Winter Garden and other buildings in the WFC and BPC. It would continue the tradition in the downtown area where technologically advanced modern buildings have been constructed near older, historic structures. It is also anticipated that Calatrava's design would be modern and unique to the area, and that the new terminal may become an important visual resource for the study area. In addition, its use would be consistent with the historic transportation uses associated with the Project Site. The terminal building would not block any unique views or view corridors, as views across the Project Site will be blocked by construction associated with redevelopment of the WTC site. As it is expected that the proposed terminal building would be an improvement over current conditions and would introduce an important architectural resource to the study area, it is not expected to have an adverse impact on the urban design or visual resources of the study area.

It is anticipated that the underground concourse to the WFC would be an improvement over existing conditions because its construction would allow for the removal of the temporary bridge over Route 9A at Vesey Street. The removal of this bridge would improve view corridors along Route 9A and surrounding streets in the study area. A new headhouse would be located in front of the Winter Garden. The headhouse would provide access to and from the Route 9A

connection. It would be a canopy of steel and glass and would be similar in scale to the temporary WTC PATH Station entrance. It is anticipated that the headhouse would complement the modern style of the Winter Garden. Figure 7-9 is a schematic of the proposed headhouse.

It is not anticipated that the vent structures would block any views or view corridors. The vent structures would be located in the Route 9A median, west of the WTC site. The location of the north vent structure would not block the Fulton Street view corridor, while the south vent structure would not block the Liberty Street view corridor. The vent structures would not block views north or south on Route 9A, as they would be slender in massing and would be located within the roadway median. Surrounding each vent structure, trees would be planted in the median as part of greening improvements to Route 9A. It is expected that this landscaping would occur concurrent with landscaping for the Route 9A Project in or around 2007.

It is anticipated that these trees would be 35 feet in height within five years of planting, thus obscuring views of the vent structures from pedestrians and vehicular traffic (see Figures 7-10 and 7-11). It is anticipated that the vent structures would be clad in reflective material that would be in keeping with modern materials used on buildings in the immediate area. This reflective material would also help the vent structures to blend in with their natural surroundings. Although the vent structures would be located west of the WTC site, it is not anticipated that these structures would impact the WTC site, as they would not block views towards the site and tall trees would obscure views of these structures from the WTC site. Likewise, it is not anticipated that these vent structures would have any impact on the WFC. Overall, it is not anticipated that the vent structures would have an adverse impact on view corridors or visual resources located within the study area, as they would not block any view corridors or views to visual resources and would be further obscured by tall trees that would be planted in the Route 9A median.

DESIGN YEAR (2025)

FUTURE COMMON TO ALL ALTERNATIVES

By 2015, it is assumed that the full program for the WTC site would be developed, with the completion of the three towers on the east side of the WTC site and a fifth tower south of Liberty Street. A 65-story office building (Tower 2) and a 25-story hotel would be completed in the northeast quadrant. In the southeast quadrant, a 62-story office building (Tower 3) and a 58-story office building (Tower 4) would be completed. A 57-story office building (Tower 5) would be completed south of Liberty Street. Two office towers would also be developed at 130 and 140 Liberty Street. The Fulton Street Transit Center would be complete, east of the Project Site. It is expected that these new developments would create shadows typical of the urban context of Lower Manhattan.

NO ACTION ALTERNATIVE

Project Site

In 2025 without the Preferred Alternative, it is assumed that the temporary WTC PATH station would still be located on the Project Site, unless removed by a separate undertaking and would not be operational. Construction activities associated with the WTC Memorial and Redevelopment Plan would be complete on site.

(facing east from the Winter Garden)

Figure 7-11
Proposed Route 9A Vent

Study Area

It is not expected that this alternative would have any adverse impact to urban design features or visual resources.

PREFERRED ALTERNATIVE

Project Site

All work associated with this alternative would have been completed for a period of 16 years after its initial operation. It is assumed that in 2025, the Preferred Alternative would be in operation and would continue to be compatible with and supportive of urban design features and visual resources on the WTC site. This alternative would bring workers and visitors who would enliven the Project Site and surrounding neighborhood by bringing increased pedestrian traffic. Therefore, it is not anticipated that this alternative would have an adverse impact on the urban design or visual resources of the Project Site.

Study Area

In the future, urban design characteristics of the study area may change. Changes to urban design features, visual resources, or to their settings may occur irrespective of this alternative.

In 2025, it is assumed that the Preferred Alternative would continue to be compatible with and supportive of urban design features and visual resources of the study area. It is anticipated that Calatrava's modern design for the Preferred Alternative would be unique to the study area and that the Terminal may become an important visual resource. It is expected that this alternative would be an improvement over current conditions and, therefore, would not result in any adverse impact to the urban design or visual resources of the study area.

E. MITIGATION

The Preferred Alternative would not result in adverse impacts to urban design or visual resources. Specific measures have been proposed that would minimize or avoid adverse impacts to the urban design and visual resources of the study area. The north and south vent structures would be slender in massing and trees would be planted around them. It is expected that this landscaping would occur concurrent with landscaping for the Route 9A Project. It is anticipated that these trees would be 35 feet in height within five years of planting and would thus obscure views of the vent structures from pedestrians and vehicular traffic. It is also anticipated that the vent structures would be clad in reflective material that would help them blend in with their natural surroundings. ✷

A. INTRODUCTION

The assessment of potential impacts to transportation facilities associated with the Preferred Alternative has been divided into four sections as follows:

- Chapter 8, Section A, "PATH";
- Chapter 8, Section B, "Vehicular Traffic and Parking";
- Chapter 8, Section C, "Transit," which includes non-PATH transit modes such as subway, bus, and ferry; and
- Chapter 8, Section D, "Pedestrians."

These sections describe transportation conditions in the vicinity of the Project Site and identify the potential for significant impacts of the Preferred Alternative. The analyses address conditions in the area once the Permanent World Trade Center (WTC) PATH Terminal is fully operational in 2009, further in the future in its 2025 design year, and when the Terminal is under construction. Chapter 15, "Cumulative Effects," includes an assessment of cumulative impacts when several proposed Lower Manhattan projects including the Permanent WTC PATH Terminal, the World Trade Center Memorial and Redevelopment Plan, Fulton Street Transit Center, Route 9A Project, and South Ferry Terminal, are in simultaneous construction and operation.

B. ANALYSIS FRAMEWORK FOR THE PROJECT ALTERNATIVES

NO ACTION ALTERNATIVE

As described in Chapter 2, "Project Alternatives," the No Action Alternative could result in the closure of the temporary station and full disruption of PATH service to Lower Manhattan at some point between the 2009 opening year and 2025 design year. The Port Authority of New York and New Jersey (PANYNJ) would work to maintain service to the extent possible, but as passenger volumes increase, the temporary station would have severe operating constraints that would limit its ability to safely and efficiently process riders. For analysis purposes, it has been assumed that absent the Preferred Alternative, those traveling between New Jersey and Lower Manhattan would be diverted to other modes of travel in the design year. In order to assess the probable impacts of this diversion to the regional and Lower Manhattan transportation networks, it was necessary to estimate the percentage of former PATH riders that would divert to each mode. To estimate this modal diversion from the temporary WTC PATH station, a number of assumptions were required, including:

- The WTC area would be redeveloped to accommodate the volume of workers similar to pre-September 11, 2001 levels, as current redevelopment plans indicate.
- All PATH stations would be fully operational, excluding the WTC PATH Terminal.

- Waterway ferry services between Lower Manhattan and west-of-Hudson locations would provide service, frequency, and passenger capacity levels similar to post-September 11, 2001 and prior to the opening of the temporary WTC PATH station.
- Some express bus service from west-of-Hudson locations would be implemented or would be diverted from the Port Authority Bus Terminal (PABT) to Lower Manhattan.

Based on these assumptions, west-of-Hudson travelers wishing to reach the Lower Manhattan area would have several mode options to cross the Hudson River including:

- Auto
- Bus to Lower Manhattan
- Bus to PABT, and then connect to Lower Manhattan-bound New York City Transit (NYCT) subway
- Commuter rail, and then connect to Lower Manhattan-bound NYCT subway
- Commuter van
- Ferry
- PATH to a Manhattan station other than WTC, such as Christopher Street or 9th Street, and then walk or connect to the NYCT subway to Lower Manhattan

Several resources were used to estimate the percentage of PATH riders that would divert to these modes, absent the Preferred Alternative. These sources included ridership data for both pre- and post- September 11, 2001, PATH passenger surveys conducted in June 2001, and the 2002 survey at PATH's Christopher and 9th Street stations.

The results of this modal diversion analysis are provided in Table 8-1. The estimates presented in Table 8-1 are integral components of the "Probable Impacts" portion in each of the four sections of this chapter, "PATH," "Traffic and Parking," "Transit," and "Pedestrians." Table 8-1 also provides an estimate of the number of former alighting and boarding WTC PATH passengers that would utilize each mode on an average weekday in 2025.

Table 8-1
No Action Alternative: Diversion of WTC PATH Riders

Mode	Percent	Year 2025 Diverted Weekday Passenger Trips
Auto	5	8,086
Bus to Lower Manhattan	21	33,961
Bus to PABT / NYCT Subway	5	8,086
Commuter Railroad / NYCT Subway	18	29,109
Commuter Van	1	1,617
Ferry	35	56,601
Uptown PATH / NYCT Subway	15	24,258
Total	100	161,718

Note: The "Diverted Weekday Passenger Trips" are a worst-case scenario as they were derived using the projected number of trips anticipated for the Permanent WTC PATH Terminal. Without this investment in public transportation infrastructure, the number of trips to Lower Manhattan from west-of-Hudson locations would be somewhat less.

PREFERRED ALTERNATIVE

The number of future trips to Lower Manhattan is expected to increase from today through the Permanent WTC PATH Terminal's 2025 design year. Some of these trips would be attributed to private development projects planned for the area. Others would be the direct result of newly constructed buildings and uses on the WTC site, including office towers, retail, cultural facilities, and a memorial.

The Preferred Alternative would be an enhancement to a travel mode that existed both prior to September 11, 2001 and in a temporary capacity today. However, the long-term operation of the Preferred Alternative is not expected to result in a shift in the modal distribution of trips to and from Lower Manhattan as compared to pre-September 11, 2001 conditions. Thus, the Terminal itself would not induce new ridership. Rather, it would provide for the additional capacity and enhanced passenger amenities needed to support the independent growth in trips to and from Lower Manhattan.

C. EVALUATION OF PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

Not all of the travel modes (PATH, vehicles, subway, bus, ferry, and pedestrians) are critical in terms of their potential for significant impacts. For example, the Preferred Alternative is not expected to create adverse vehicular traffic impacts in its operational phase since the Terminal that was destroyed on September 11, 2001 generated a minimal volume of auto and taxi trips. Based on surveys conducted by PANYNJ, 1 percent of connecting trips to or from the PATH were made by auto and less than ½ percent were made by taxi. Thus, the vehicular traffic analyses that follow focus principally on potential impacts during construction, identifying the volume of construction traffic generated by the project and the routes to be used by trucks accessing the site.

The Preferred Alternative would provide greater capacity than the Terminal that was destroyed on September 11, 2001, but its construction is not expected to induce new PATH ridership beyond levels that were forecasted prior to the terrorist attacks. Although PANYNJ projections show an increase in ridership through the project's design year, these new riders would be attributed to private development that was anticipated prior to September 11 2001 or from redevelopment efforts that are independent of the Permanent WTC PATH Terminal but are in response to the terrorist attacks. Since the Preferred Alternative is not expected to induce new riders, it would not increase subway patronage above that which would have occurred otherwise. It is possible that different access/egress points to the street network above could affect pedestrian crossing locations and create impacts or benefits to levels of service for on-street facilities, which is addressed in Chapter 8, Section D.

The analyses of each mode begin with a description of existing conditions both pre- and post-September 11, 2001 and proceed with an assessment of projected conditions during the construction period, design year, and opening year. ✳

A. INTRODUCTION

This section describes the pre- and post-September 11, 2001 PATH system, the original World Trade Center (WTC) PATH Terminal, the temporary WTC PATH station, and the Permanent WTC PATH Terminal. This section also identifies whether the No Action and Preferred Alternatives would create impacts to the PATH system in terms of operations and ridership. The analyses that follow provide an overview of existing conditions, pre- and post-September 11, 2001, in order to establish a baseline from which future conditions may be assessed. Additional information on PATH's ridership projections and planning and design requirements for a new terminal are presented in Appendix C.

The Port Authority of New York and New Jersey (PANYNJ) does not expect the Permanent WTC PATH Terminal itself to induce PATH ridership beyond growth that was projected prior to September 11, 2001. Rather, the Preferred Alternative seeks to serve customers who previously used the PATH system and the former WTC PATH Terminal, and to accommodate the growing ridership that PATH had experienced in the past and would have continued to occur in the future absent the events of September 11, 2001. Other land uses surrounding the Project Site, such as the WTC Memorial, will induce additional trips to Lower Manhattan which will need to be accommodated.

The Preferred Alternative would be designed to adequately serve projected ridership levels through its 2025 design year. Shortcomings of the original WTC PATH Terminal, such as its difficulty in accommodating reverse passenger flows, will be addressed in the design of the Preferred Alternative, thereby improving the level of service that existed previously.

The Preferred Alternative would also result in improved connections to subway service and Hudson River ferries as compared to the pre-September 11, 2001 and temporary PATH facilities at the WTC site. The potential effects of these improved connections are described later in this chapter as well as in Chapter 8, Section C, "Transit."

The Preferred Alternative is a functional replacement and improvement of the WTC PATH Terminal that previously existed on the WTC site. In time, as the WTC site is redeveloped, and other previously planned or anticipated development occurs in Lower Manhattan, a fully functioning PATH system would be a necessary component in the public transportation system and the overall transportation network for the region in terms of both capacity and redundancy. Due to the substantial capacity, pedestrian, and component service life limitations of the temporary WTC PATH station that is currently in service, the only means by which to return the PATH rail system to its former capacity and service capabilities, and to accommodate projected future ridership, is to implement the Preferred Alternative, for the Permanent WTC PATH Terminal.

B. METHODOLOGY

The analyses begin with a description of the WTC PATH Terminal and the operation of the PATH system both pre- and post-September 11, 2001. System operations were reviewed in terms of train frequencies and system capacity.

Historical ridership data was compared and analyzed. This analysis included a review of total PATH system demand and WTC PATH Terminal demand from year to year, and a comparison of average weekday ridership trends for the system as a whole and for the WTC PATH Terminal over time. Peak period demands were also assessed for the WTC PATH Terminal.

"Existing conditions" service and ridership information, which comprise both historical (pre-September 11) and current (post-September 11) data, was then compared to the expected system operations and ridership once the Preferred Alternative would open in 2009 and to the Terminal's 2025 design year. The analyses presented in this section were performed using available historical ridership data, ridership projections, and system operations information.

If the Preferred Alternative is not constructed, it is expected that the temporary WTC PATH station that is presently operating would continue to maintain service to the extent possible. This is the No Action Alternative, which was fully described in Chapter 2, "Project Alternatives." However, increasing passenger volumes over time would substantially surpass the safe and efficient design capacity of the temporary WTC PATH station prior to the 2025 design year. Once the design capacity of the temporary WTC PATH station is reached, PANYNJ would need to implement restrictive measures to ensure passenger safety and reliable PATH rail operations. One such measure may include restricting passengers from entering the WTC station during AM peak hours as was done at the Christopher Street station following September 11, 2001. Another measure may be to reduce the number of trains serving the WTC station so as to allow sufficient station egress prior to another train discharging passengers. Such measures would not only fail to serve passenger demand, but they would also have operational repercussions throughout the PATH rail system. Due to these impacts, for analysis purposes, it was assumed that absent the Preferred Alternative, those traveling between New Jersey and Lower Manhattan would be diverted to other modes of travel as described in the "Introduction" to this Transportation Chapter.

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

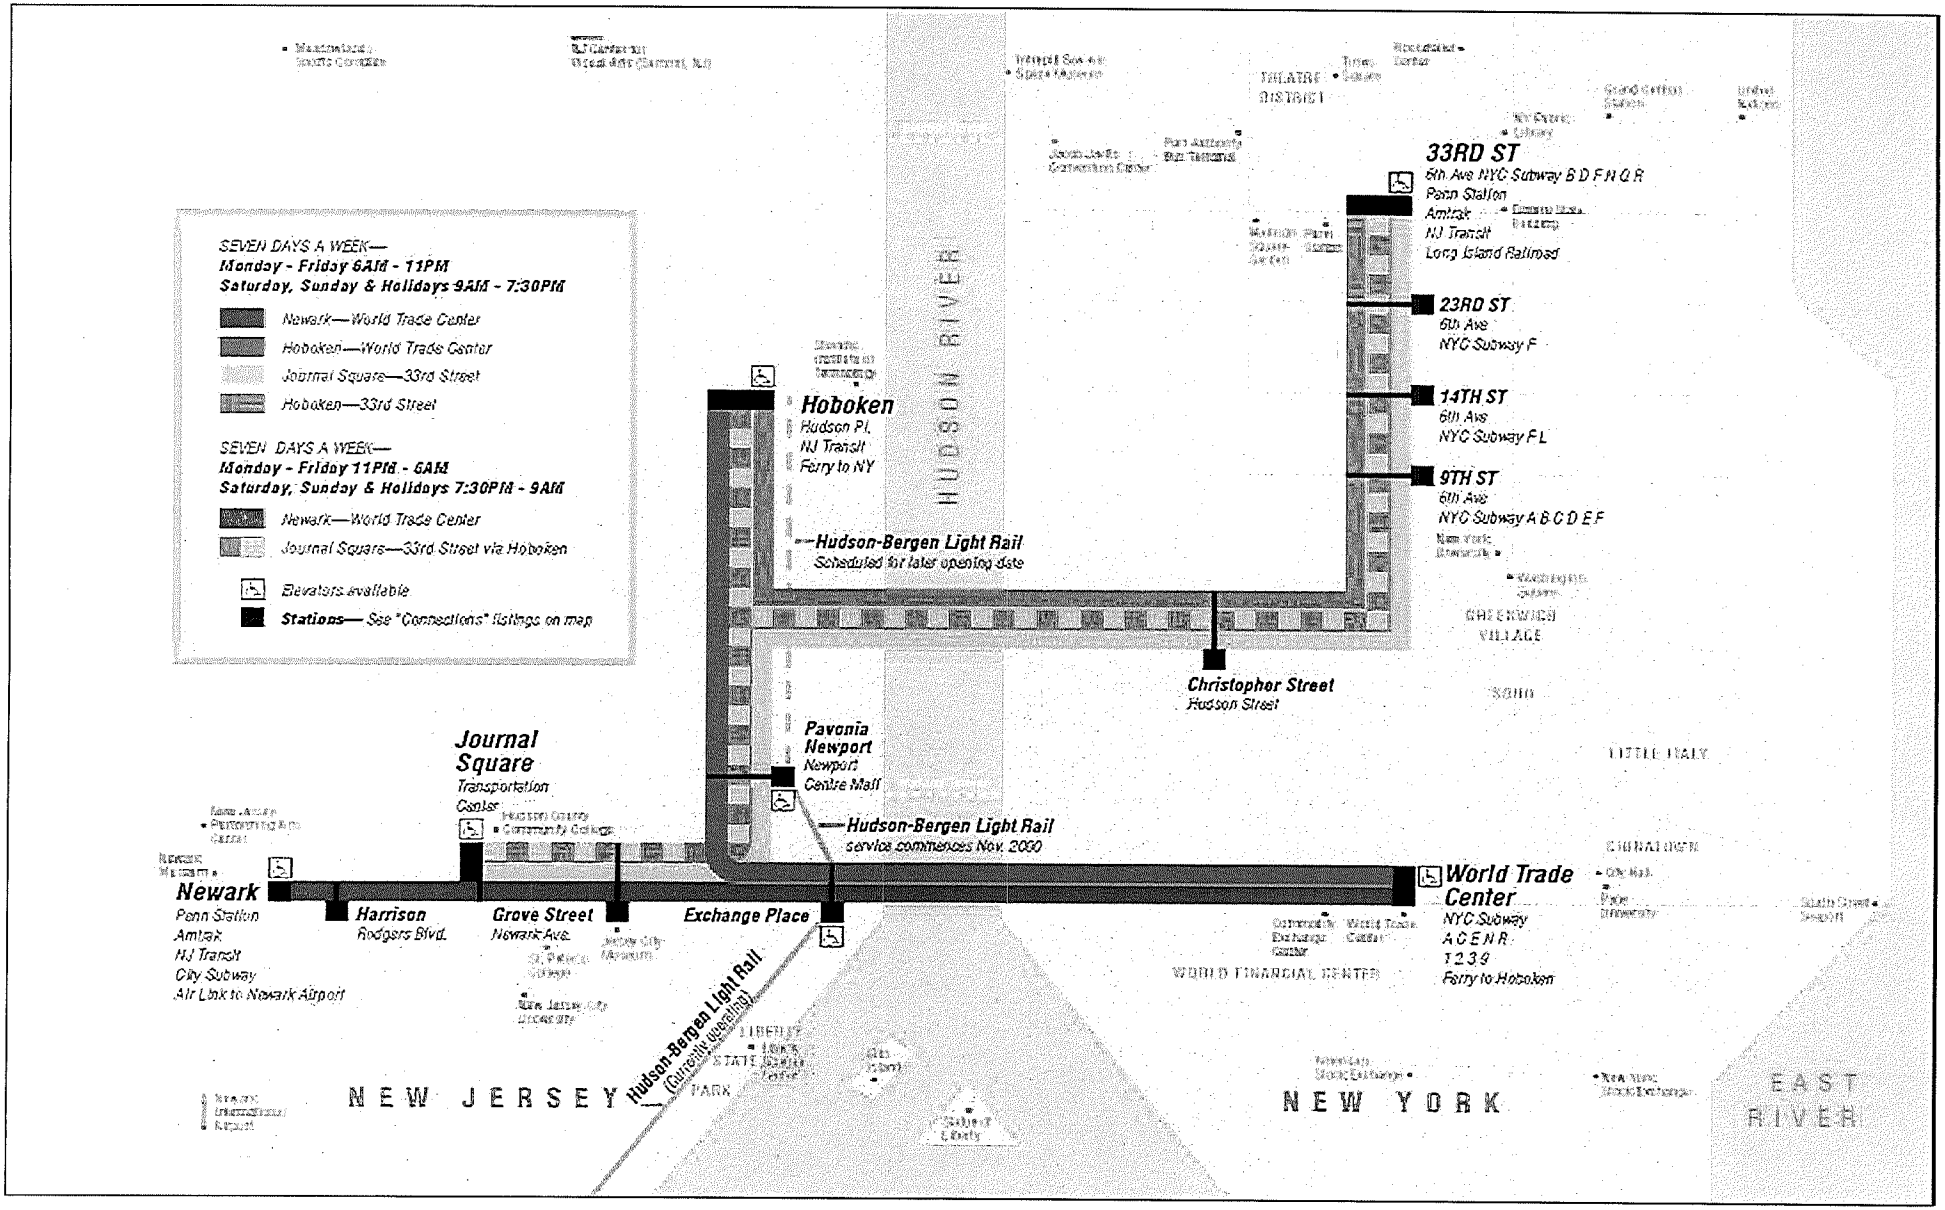
PRE-SEPTEMBER 11, 2001 BASELINE CONDITIONS

OPERATIONS

Prior to September 11, 2001, the PATH system operated 24 hours per day, seven days per week. Figure 8A-1 provides a map of the PATH system as it then operated. Service was provided along the following four lines:

- Newark-World Trade Center;
- Hoboken-World Trade Center;
- Journal Square-33rd Street; and
- Hoboken-33rd Street

During the late night hours and weekends, some of the routes were combined.



PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure 8A-1
PATH System

The PATH system encompassed a total of 13 stations, six of which were located within New York City and seven in New Jersey. Table 8A-1 provides the locations of each of these stations and the connecting transportation services that were available.

Table 8A-1
PATH Stations and Nearby Connecting Transit Services

Station	Location	Connecting Service
World Trade Center	Fulton Street at Church Street New York, NY	NYCT Subway; NY Waterway and Water Taxi ferries; NYCT and private bus service
Christopher Street	Christopher St. between Greenwich and Hudson Streets, New York, NY	NYCT Subway; NYCT bus service
9th Street	Sixth Ave. at 9th St., New York, NY	NYCT Subway; NYCT bus service
14th Street	Sixth Ave. at 14th St., New York, NY	NYCT Subway; NYCT bus service
23rd Street	Sixth Ave. at 23rd St., New York, NY	NYCT Subway; NYCT bus service
33rd Street	Sixth Ave. between 30th and 33rd Streets, New York, NY	Amtrak; NJ Transit and LIRR commuter rail; NYCT Subway; NYCT and private bus service
Exchange Place	Montgomery St. at Hudson River, Jersey City, NJ	Hudson-Bergen Light Rail; NY Waterway ferry; NJ Transit and local bus service
Grove Street	Newark Ave. between Grove St. and Luis Muniz Marin Boulevard, Jersey City, NJ	NJ Transit and local bus service
Harrison	Frank E. Rodgers Boulevard between Somerset and Cape May Streets, Harrison, NJ	NJ Transit bus service
Hoboken	Hudson Place at River Street, Hoboken, NJ	NJ Transit commuter rail; NY Waterway ferry; NJ Transit and local bus service
Journal Square	Kennedy Boulevard between Pavonia and Sip Avenues, Jersey City, NJ	NJ Transit and local bus service
Newark	1 Penn Plaza West, Newark, NJ	Amtrak and NJ Transit commuter rail; Newark City Subway; Greyhound and NJ Transit and local bus service
Pavonia/Newport	Washington Blvd. at Pavonia Ave., Jersey City, NJ	Hudson-Bergen Light Rail; NY Waterway ferry; NJ Transit and local bus service

PATH directly served communities in Manhattan, Jersey City, Newark, Harrison, Hoboken, and also provided connections for other west-of-Hudson residents. At Newark-Penn Station, PATH customers could access Amtrak; New Jersey Transit's (NJ Transit) Northeast Corridor, Raritan Valley, and North Jersey Coast commuter rail lines; the Newark City Subway; and bus and rail service to Newark Liberty International Airport. At Hoboken, PATH connected with NJ Transit Boonton, Morris & Essex, Main/Bergen County, Pascack Valley, North Jersey Coast and Port Jervis commuter rail lines; numerous NJ Transit bus routes; and NY Waterway ferry service. In New York, PATH stations were located in close proximity to New York City Transit (NYCT) subway stations on the Broadway, Sixth, Seventh, and Eighth Avenue lines. Connections to NYCT and privately operated bus routes, ferries, and commuter rail service were also available.

Prior to September 11, 2001, PATH maintained a fleet of 334 cars. A total of 288 cars would be required for AM peak period revenue operation. In addition, PATH maintained two 7-car gap trains—one, 7-car consist on the Newark-WTC Line and one, 7-car consist on the Journal Square-33rd Street Line. Thus, PATH's AM peak period operating fleet consisted of 302 cars. The remaining 32-cars were rotated with the operating fleet to facilitate car inspection and maintenance.

PATH would operate its peak schedules between 7:30AM to 9AM (AM peak period) and from 4:30PM to 6:00PM (PM peak period). Headways would fluctuate during this period with a maximum operation in the hours from 8AM to 9AM (AM peak hour) and 5PM to 6PM (PM peak hour). In the AM peak period, PATH was operating a total of 39 train consists through the system. Train consists ranged in length from 7-cars to 8-cars. Headways on the system ranged from 3 minutes on the Newark-WTC Line to 6 minutes on the Hoboken-33rd Street Line. Table 8A-2 summarizes the pre-September 11, 2001 operations for the PATH system.

Table 8A-2
Pre-September 11, 2001 PATH Train Operations

Route	Consists for Revenue Operation	Consist Length	Operating Headway
Newark-WTC	15 consists	8-cars	3 to 4 minutes
Hoboken-WTC	7 consists	7-cars	3 to 4 minutes
Journal Square-33rd Street	11 consists	7-cars	4 to 5 minutes
Hoboken-33rd Street	6 consists	7-cars	6 minutes
Notes: PATH maintained 1, 7-car gap train for use on the Newark-WTC Line and 1, 7-car gap train for use on the Journal Square-33rd Street Line.			

When accounting for run times, the total of 22 consists operating on the Newark-WTC and Hoboken-WTC Lines translated to 31 runs through the WTC Terminal in the AM peak hour. There were 16 runs in each direction on the Newark-WTC Line and 15 runs in each direction on the Hoboken-WTC Line. At the peak commuter period within the peak hour, PATH would maintain 3 minute headways on both routes, as required to support ridership system-wide.

During midday and evening periods, PATH would operate all four with 10- to 15-minute headways, depending upon the route. During overnight hours, weekends, and holidays, PATH would suspend Hoboken-WTC service and would modify its Journal Square-33rd Street Line to stop at Hoboken-Terminal. The Newark-WTC Line would operate at all times. The headways during these periods ranged from 15-minutes to 60-minutes.

During non-peak periods, PATH would store trains at 4 locations: Journal Square Yard; Harrison Yard; Newark South Street Yard; and the World Trade Center Terminal. The later of these storage locations was used only for trains operating on the Hoboken-WTC Line. The other yards would store trains that operated on all four PATH routes. In addition, PATH would store one train at the 33rd Street station.

WTC PATH TERMINAL

The WTC PATH Terminal opened in 1971. It was constructed in the portion of the WTC site referred to as the "bathtub" and was located beneath the WTC's office and retail space. The Terminal was fully compliant with the Americans with Disabilities Act (ADA), and it was the first station in the world to be fully air-conditioned.

The platform level contained three 10-car platforms and five tracks. The tracks and platforms of the station formed a "loop" with the projections of the Hudson River tunnels. Trains entered the station from New Jersey via the south Hudson River tunnel (Tunnel F) and exited to New Jersey via the north Hudson River tunnel (Tunnel E). Thus, trains entered and left Manhattan without changing the location of the train's engineer or conductor, resulting in a short dwell time at the Terminal.

The easternmost platform (Platform A) served Track 1 and was used in the event of an equipment failure, for train storage, and for alighting trains that terminated revenue service at the WTC Terminal. Platform B and Tracks 2 and 3 and served the Hoboken-WTC Line. Platform C and Tracks 4 and 5 and was used for the Newark-WTC Line.

A mezzanine level was located above the platforms, which housed fare equipment, vertical circulation between the platform level and other levels above, and accessory retail and food stalls. The principle access between the mezzanine and the WTC retail concourse was a bank of escalators that traveled underneath NYCT's 1 and 9 line. The escalators terminated in an area of the WTC retail concourse known as PATH Square.

PATH Square was located in the northeast section of the WTC retail concourse. The retail concourse provided weather-protected connections between PATH, the office buildings on the WTC site, the World Financial Center, three NYCT subway stations, and the streets adjacent to the WTC. Within the retail concourse, PATH passengers could access the Cortlandt Street Station on NYCT's 1 and 9, and N and R lines, and the WTC Station on the E line. A circuitous connection was also available to both the Park Place Station for the 2 and 3 lines and the Chambers Street Station for the A and C lines. The retail concourse had street-level access from Church, Vesey, West, and Liberty Streets. Two pedestrian overpasses over Route 9A provided access between the World Financial Center and the WTC.

The WTC PATH Terminal, which served as the only station on the New York side of the Hudson for two of PATH's four routes, was destroyed during the terrorist attacks of September 11, 2001. As a result, the PATH system lost a substantial portion of its capacity to serve commuters throughout the region, and public transit access to Lower Manhattan was substantially impacted as other transit providers sought to serve former PATH customers.

RIDERSHIP

Prior to September 11, 2001, the PATH system had approximately 257,000 boardings on an average weekday. Table 8A-3 provides historical average weekday boardings for the PATH's major stations and for the PATH system as a whole for the years 1992 to 1999. As shown in the table, ridership for the PATH system increased over time, as did boardings at the former WTC PATH Terminal itself.

Table 8A-3
Average Weekday Ridership for Selected PATH Stations: 1992 to 1999

Station	1992	1993	1994	1995	1996	1997	1998	1999
WTC	54,160	52,771	55,053	51,319	52,980	55,893	58,110	60,385
Newark	25,639	25,580	26,570	25,660	27,143	28,725	29,910	31,065
Journal Sq.	21,508	21,336	21,630	21,271	22,204	23,279	23,821	25,237

33rd Street	20,502	21,633	22,731	24,430	22,979	22,176	23,149	22,604
System Total	195,682	197,923	206,887	206,304	207,990	215,170	223,164	232,351

The original WTC PATH Terminal was the busiest station in the PATH system with approximately 67,000 average weekday boardings, or an average two-way ridership of approximately 142,300 weekday riders.

Volumes at the former WTC PATH Terminal were heaviest during the AM and PM peak hours. During these periods, the principal direction of travel would be inbound to Manhattan in the morning and outbound to New Jersey in the evening; however, approximately 15 percent of the ridership would commute in the reverse direction. During the morning peak hour (8 AM to 9 AM), a total of approximately 26,600 riders used the terminal, with 22,500 alighting the system and 4,100 boarding. During the evening peak hour (5 PM to 6 PM), the terminal handled 20,400 riders, of which approximately 16,100 boarded PATH and 4,300 alighted.

Table 8A-4 shows the origins and destinations of PATH riders within Lower Manhattan during the AM and PM peak hours based on surveys conducted by the PANYNJ in 1996. For those commuting to Lower Manhattan from New Jersey in the AM peak hour, the majority (61 percent) were destined to buildings beyond the WTC site, 24 percent were destined to the WTC site itself, and the remaining 15 percent connected to NYCT subways. Figure 8A-2 illustrates the above and the associated passenger flow distribution in Lower Manhattan. For those leaving Lower Manhattan via PATH in the AM peak hour, 65 percent accessed the system from NYCT subways, 3 percent from the WTC site itself, and another 32 percent from other locations in Lower Manhattan. Similar origins and destinations were observed for the PM peak hour.

Table 8A-4
Pre-September 11, 2001 Origins and Destinations of Riders at the WTC PATH Terminal

Origin/Destination	Commuters to Lower Manhattan		Commuters from Lower Manhattan	
	AM Peak (Exit PATH)	PM Peak (Enter PATH)	AM Peak (Enter PATH)	PM Peak (Exit PATH)
NYCT Subways	15%	19%	65%	65%
WTC Site	24%	25%	3%	4%
Other Lower Manhattan	61%	56%	32%	31%

Table 8A-5 shows the origins/destinations for those traveling between the WTC PATH Terminal and off-site developments. For those commuting to Lower Manhattan from New Jersey in the AM peak hour, the primary off-site destination was southeast from the WTC site toward the Financial District, representing about 40 percent of the total off-site trips (see Figure 8A-2). Trips to the north (Tribeca), northeast (Civic Center), and west (World Financial Center and Battery Park City) were fairly evenly distributed, each representing about 16 to 20 percent of the total off site trips. In the PM peak hour, there were a lower percentage of trips entering PATH from off site; however, the distribution of these trips was similar to the AM peak hour.

For those commuting from Lower Manhattan to New Jersey in the AM peak hour, the majority (62 percent of the total off-site trips) entered the WTC PATH Terminal from the northeast. Another 19 percent entered from the north (Tribeca), 13 percent from the southeast (Financial District), 5 percent from the west (World Financial Center and Battery Park City), and 1 percent from the south. A similar pattern of off-site trips was observed during the PM peak hour.

Approximately 5,900 and 5,700 commuters transferred between PATH and NYCT's subways during the AM and PM peak hours, respectively. The transfer to/from NYCT's WTC Station (A,

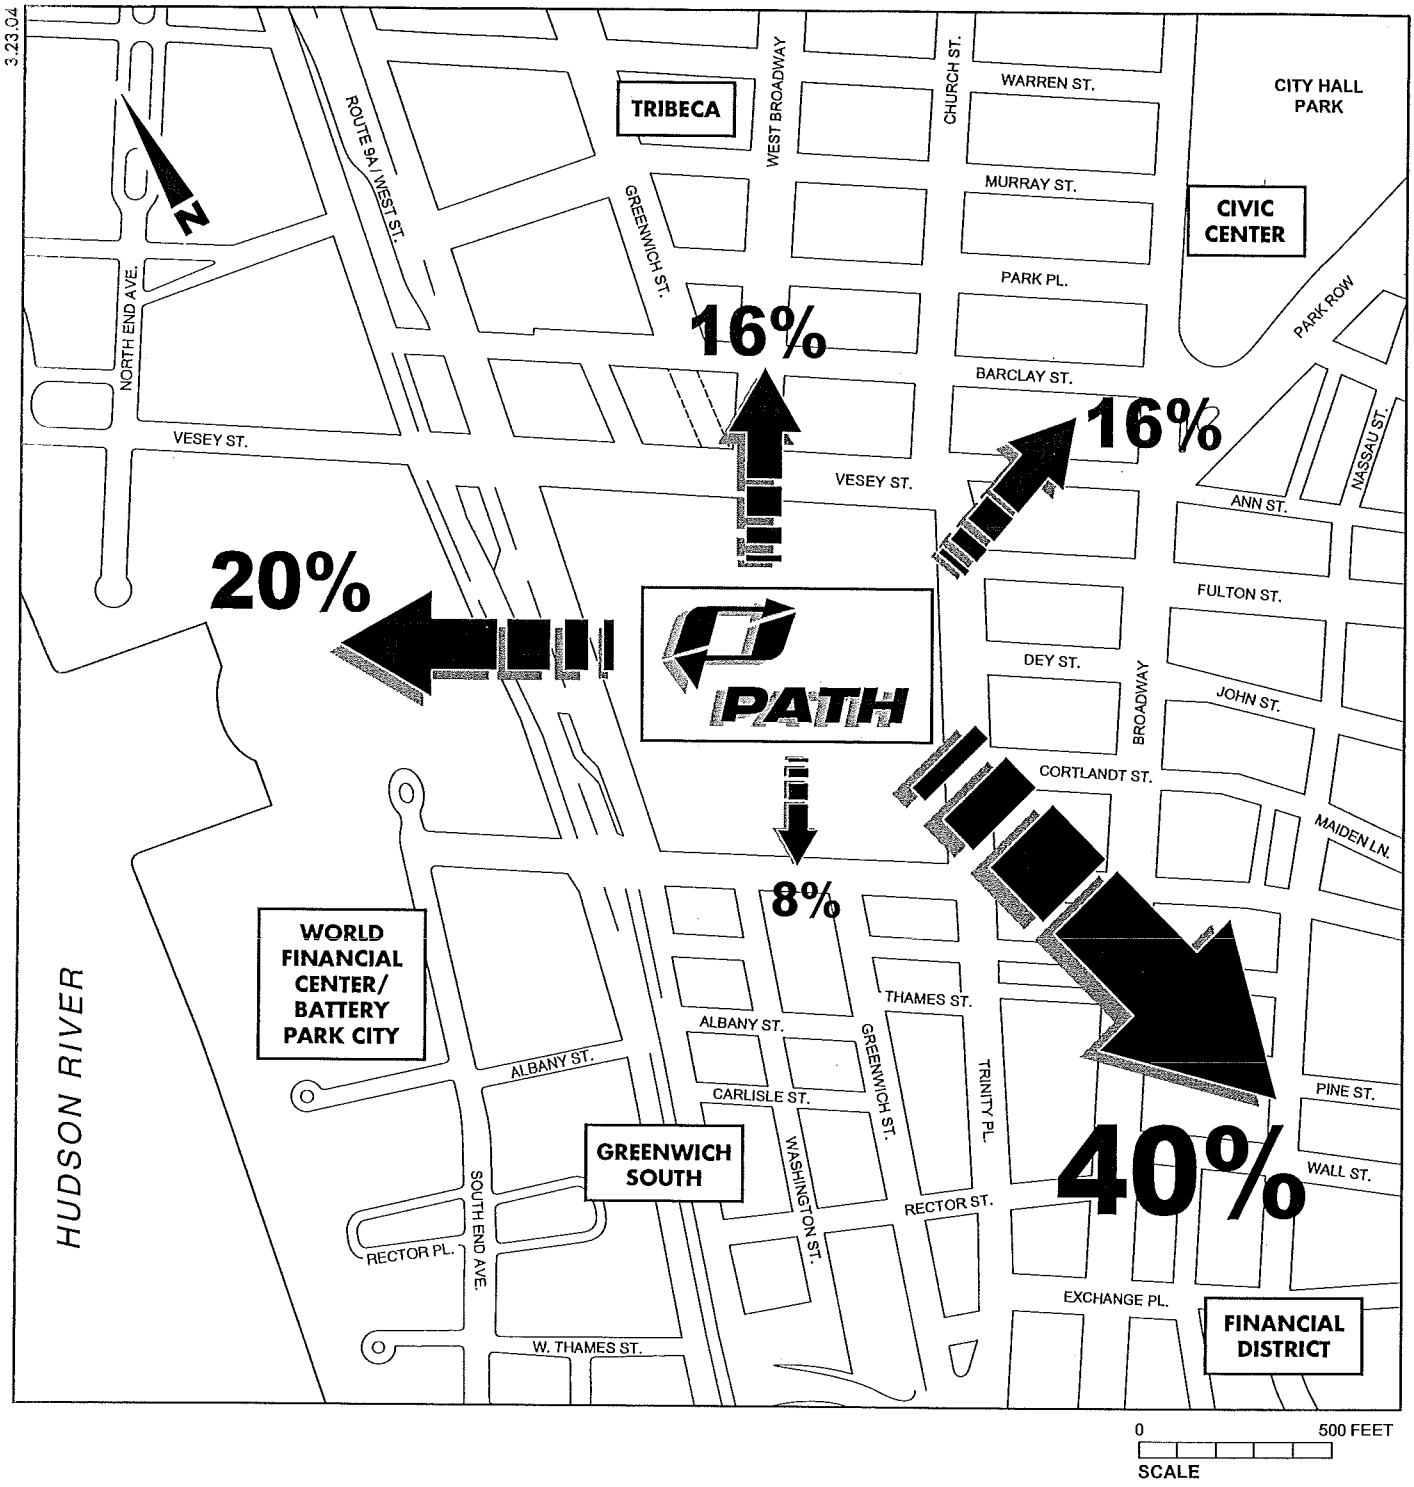

Figure 8A-2

Pre-September 11, 2001 Conditions Off-Site Destinations of AM Peak Hour PATH Riders

C, E, 2, and 3 trains) was the most heavily used, representing approximately 55 percent of the transfer volume. One-third of the transfers were between PATH and NYCT's N and R trains and the remaining 12 percent transferred to or from NYCT's 1 and 9 trains.

Table 8A-5
Pre-September 11, 2001 Off-Site Origins and Destinations of Riders at the WTC PATH Terminal

To/From	Commuters to Lower Manhattan		Commuters from Lower Manhattan	
	AM Peak (Exit PATH)	PM Peak (Enter PATH)	AM Peak (Enter PATH)	PM Peak (Exit PATH)
West (World Financial Center and Battery Park City)	20%	17%	5%	6%
North (Tribeca)	16%	21%	19%	28%
Northeast (Civic Center)	16%	22%	62%	53%
Southeast (Financial District)	40%	32%	13%	13%
South (Greenwich South)	8%	6%	1%	1%

CHANGES IN THE AFFECTED ENVIRONMENT SINCE SEPTEMBER 11, 2001

CHANGES IN THE PATH SYSTEM

The WTC PATH Terminal and a seven-car PATH train were destroyed during the terrorist attacks of September 11, 2001. Subsequently, Tunnels E and F were flooded, and PATH's Exchange Place Station in Jersey City, New Jersey, was damaged and rendered inoperable because the track configuration would not permit trains to reverse direction before entering the Hudson River tunnels. As a result, the PATH system lost a substantial portion of its capacity to serve commuters throughout the New York and New Jersey region, which substantially hindered public transit access to Lower Manhattan. All remaining PATH service following September 11, 2001 and prior to the opening of the temporary WTC PATH station was rerouted to terminate in New Jersey or at the 33rd Street PATH station.

CHANGES IN PATH RIDERSHIP

Before September 11, 2001, the PATH system served approximately 257,000 passengers each weekday. Prior to the reopening of the Exchange Place Station, which occurred on June 29, 2003, and the opening of the temporary WTC PATH station on November 23, 2003, approximately 160,000 passengers used the system each weekday, a reduction of about 97,000 passengers, or almost 38 percent.

Ridership fell precipitously on the Newark-WTC and Hoboken-WTC lines as access to Manhattan was no longer available on these routes. Some riders chose to divert to the Journal Square-33rd Street or Hoboken-33rd Street lines, thereby increasing ridership on these uptown-bound trains. PATH passengers destined for Lower Manhattan would exit at Christopher or 9th Street and transfer to nearby NYCT subway lines. Severe crowding occurred at both of these stations, which each have only one entry/exit location, At Christopher Street, passengers were barred from entering this station on weekdays from 7 AM to 9:45 AM. In addition, trains operating from Journal Square and Hoboken to 33rd Street would not stop at Christopher Street on weekdays from 4:30 PM to 7 PM.

EFFECTS ON OTHER TRANSIT SERVICES

Due to system capacity and service reductions caused by the events of September 11, 2001, many former PATH riders were required to divert to other transportation services in order to access destinations in Lower Manhattan. Most former PATH riders chose to divert to NJ Transit commuter rail (which increased ridership approximately 30 percent system-wide), NJ Transit buses, or to trans-Hudson ferries, which increased ridership by more than 100 percent. A more extensive discussion of impacts to these other transit providers is presented in Chapter 8, Section C, "Transit."

TEMPORARY WTC PATH SERVICE

Temporary WTC PATH Station

The temporary WTC PATH station opened on November 23, 2003. The temporary WTC PATH station was designed and constructed with the primary objective of restoring PATH service to Lower Manhattan as quickly as possible following September 11, 2001. It was designed to accommodate 80 percent of the users of the original WTC PATH Terminal in 2000. This reflects the fact that 20 percent of the original WTC PATH Terminal users were bound for the WTC buildings themselves, which were destroyed on September 11, 2001.

Although the temporary WTC PATH station has allowed service to be restored, its operating capacity and functionality are limited. For example, vertical circulation elements within the terminal have a limited service life. If this station were to remain in service, various elements may require replacement before 2010. The design of the station does not easily allow for new construction above, as planned for the WTC redevelopment. Thus, as the site is redeveloped, station elements will need to be rebuilt to accommodate its construction. The temporary WTC PATH station would also not easily support connections to future buildings on the WTC site.

The temporary WTC PATH station has substantially the same operating configuration as the terminal that existed on the WTC site prior to September 11, 2001. As before, trains enter the station from New Jersey via the south Hudson River tunnel and exit to New Jersey via the north tunnel thereby forming a loop in the PATH system that allows trains to enter and leave Manhattan without requiring the train operator to change positions. Also like the original terminal, the temporary station has five tracks and three platforms. The new platforms, however, accommodate eight-car PATH trains as compared to the 10-car platforms that existed before September 11, 2001, a 20 percent reduction in capacity.

The temporary WTC PATH station includes security and fire protection equipment, but advanced passenger amenities are not provided. It is accessible to people with disabilities in accordance with the ADA, but its configuration requires four separate elevator rides to reach street level.

The temporary WTC PATH station consists of five levels—platform, mezzanine, 1 and 9 underpass, concourse, and street level. Passengers must use a series of escalators and/or elevators to travel between the platform and the street- and concourse-level entrances. Pedestrian access to the temporary WTC PATH station is limited due to the anticipated continued construction at the WTC site. All patrons must enter and exit the station at street level near the intersection of Church and Fulton Streets at the eastern boundary of the WTC site or from NYCT's WTC (E) or Cortlandt Street (R and W) subway stations.

Operations

With the reopening of PATH's Exchange Place and WTC stations in 2003, the system is now operating much as it did prior to September 11, 2001. Service frequencies are similar to pre-September 11, 2001 levels with trains running every 4 to 6 minutes during peak periods, every 10 to 15 minutes throughout the day, and every half-hour overnight. On weekends and holidays, trains operate every 15 to 30 minutes depending on the route and time of day.

With the restoration of service to the World Trade Center, PATH has resumed operations similar to the pre-September 11, 2001 condition. However, physical damage endured by the terrorist attacks and changes in ridership have resulted in the following changes:

- PATH currently maintains a fleet of 327 cars because one, 7-car train was destroyed on September 11, 2001.
- PATH currently operates 7-car trains on both the Hoboken-WTC and Newark-WTC Lines. Thus, the AM peak hour car requirement for revenue service is 252. Additionally, PATH maintains two 7-car gap trains. Thus, PATH's AM peak period operating fleet consists of 266 cars. PATH anticipates the restoration of 8-car service on the Newark-WTC Line in 2006, which would increase its AM peak hour car requirement to 278.
- Because ridership is lower than before September 11, 2001, PATH operates fewer trains per hour between Hoboken and Newark and the World Trade Center. Currently, PATH runs 15 trains on the Newark-WTC Line and 5 on the Hoboken-WTC Line in the AM peak period.

During non-peak periods, PATH stores trains as it did prior to September 11, 2001 at Journal Square Yard, Harrison Yard, Newark South Street Yard, World Trade Center, and 33rd Street.

Ridership

With PATH operations essentially restored, ridership at the temporary WTC PATH station has reached approximately 80 percent of pre-September 11, 2001 levels. As shown in Appendix C-1, the temporary WTC PATH station serves approximately 52,500 daily two-way trips.

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

CONSTRUCTION PERIOD (2006)

FUTURE COMMON TO ALL ALTERNATIVES

PANYNJ will continue or will begin upgrades to other portions of the PATH system, independent of the Preferred Alternative. Although these projects are planned independently, the outcome of this environmental review process and subsequent construction schedule for the Preferred Alternative may affect the implementation of the PATH system improvements described below.

- ***9th Street and Grove Street Station Rehabilitation.*** Due in part to substantial increases in station usage following September 11, 2001, the PANYNJ will renovate the 9th Street and Grove Street PATH Stations to include an additional entrance/exit. Currently, these stations operate with only one point of entry/exit. Other improvements such as station modernization and platform lengthening will also be performed. These projects will provide better customer convenience and safer operations at these stations.

- ***10-Car Operation.*** The PANYNJ will continue to prepare the PATH's Newark-WTC Line for 10-car operation, a program that pre-dates the terrorist attacks of September 11, 2001. PATH also eventually plans to lengthen its Hoboken-WTC train consists from 7 to 8 cars. Since September 11, 2001, PANYNJ lengthened the platforms at the Exchange Place station in tandem with the emergency repairs to the system that were required to restore service following the attacks. However, to fully implement 10-car operations, additional rolling stock must be acquired and the Harrison and Grove Street stations must be rehabilitated to lengthen platforms. It is anticipated that these improvements would be funded as part of the 2008 to 2013 Capital Plan with implementation by 2015.

- ***Signal System Upgrade.*** PANYNJ will continue a program to modernize its signals system-wide. Currently, PATH operates with a fixed-block signal system but plans to upgrade to a Communication Based Train Control (CBTC) system. The CBTC system is more flexible than the fixed-block system because it continuously updates train positions, distances, and travel speeds. This allows the system to recover more quickly from delays, because a train can follow a "delayed" train more closely without having to come to a complete stop. CBTC results in a more efficient operation that produces regular travel speed because it:

  - Allows for consistent trip times in closer conformance to the operating schedule;
  - Allows for a precise strategy for stopping accuracy;
  - Optimizes headways, which increases capacity by allowing the trains to closely follow the safe braking distance; and
  - Improves ride quality.

  Under both the fixed-block and CBTC signal systems, PATH's capacity is controlled by the track junction at Exchange Place and the throughput of the Hudson River tunnels. Prior to September 11, 2001, PATH operated 31 trains in each direction through the World Trade Center tunnels (Tunnels E and F) in the AM peak hour; thus, trains had approximately 116-second headways. PATH operated 16 trains on the Newark-WTC Line and 15 trains on the Hoboken-WTC Line. With the CBTC system, it is possible that headways could decrease to 90 seconds through the tunnels, resulting in up to 40 trains per hour. However, given projected ridership demand and other limitations within the system, PATH plans to operate fewer trains than 40 trains per hour.

  PATH will begin planning the implementation of CBTC concurrent with its contracts for fleet replacement. This arrangement will ensure consistency in the design of signal and train systems. It is anticipated that CBTC would be in place sometime between 2010 and 2015.

- ***Fleet Replacement.*** PATH currently maintains a fleet of 327 cars, much of which are more than 30 or more years old. In order to meet future ridership needs, PATH must maximize its peak hour service plan with a high degree of reliability. However, as the fleet ages, equipment failures increase; thereby, reducing PATH's ability to adhere to scheduled headways. Furthermore, PATH plans to implement 10-car train service cannot be realized without an expansion of its fleet.

  On June 17, 2004, PANYNJ announced a request for proposals to design and fabricate 246 new rail cars and to rehabilitate or replace an additional 94 cars. The new cars will have improved lighting, air conditioning and heating; cantilevered seats with room for passengers to store items under them; prerecorded station announcements; better signs; and three doors

on each side. This proposal allows PATH an option to purchase additional rolling stock to meet future demands.

- ***Fare Integration.*** When the temporary WTC PATH station opened on November 23, 2003, it was the first station in the PATH system to accept pay-per-ride MetroCards sold by the Metropolitan Transit Authority (MTA). The PANYNJ will continue to work with the MTA to integrate the PATH fare equipment throughout its rail system with the MetroCard system. The fare integration program will allow transit riders to transfer between NYCT subways and buses and PATH with a single fare card.

Furthermore, PATH will continue to increase service on its WTC Lines to meet ridership demand. In the very near future, the length of Newark-WTC trains will be increased from seven to eight cars. PATH will also increase the number of peak period runs on both routes as demand warrants.

It is assumed that some or all of these projects will be completed or will commence during the construction period for the Preferred Alternative.

NO ACTION ALTERNATIVE

The temporary WTC PATH station was designed to accommodate anticipated passenger volumes during the construction period. No impacts to PATH service are expected to either PATH passengers or to the operation of the PATH system during this period given the No Action Alternative.

PREFERRED ALTERNATIVE

It is anticipated that the Preferred Alternative can be constructed with minimal impacts to PATH's normal weekday train operations. PATH service to the temporary WTC PATH station may have to be suspended sporadically during the overnight hours on weekdays and all day on weekends to accommodate heavy construction activities.

Throughout the construction period, pedestrian access may be hindered due to sporadic closing, rerouting or narrowing of sidewalks used to access the sole entrance/exit of the temporary WTC PATH station. Pedestrian connections between PATH and the NYCT subway system may also be impacted due to rerouted or narrowed passageways. Otherwise, no construction-related impacts are anticipated for PATH riders or operations.

OPENING YEAR (2009)

FUTURE COMMON TO ALL ALTERNATIVES

In the opening year of the Preferred Alternative, it is assumed that the PANYNJ will have completed or will continue work on the system improvements described above for the construction period. These system enhancements will improve operations and will provide for enhanced customer convenience as compared to today.

As shown in Table 8A-6, projected opening year demand on an average weekday for trans-Hudson PATH service between New Jersey and the WTC site will be 125,286, approximately 12 percent less than the 142,300 daily boardings recorded in year 2000. The projected AM peak hour demand in 2009, both boardings and alightings, is approximately 23,423 passengers, or 12 percent less than in year 2000 (see Appendix C).

Table 8A-6
PATH Ridership Forecast for WTC Service in the Opening Year (2009)

Year	Average Weekday Trips			AM Peak Hour		
	Terminal Users	Weekday Boardings	Weekday Alightings	Terminal Users	Weekday Boardings	Weekday Alightings
2000	142,300	67,000	75,300	26,604	4,107	22,497
2009	125,286	58,989	66,297	23,423	3,749	19,674

NO ACTION ALTERNATIVE

If the Preferred Alternative is not constructed, then the temporary WTC PATH station that is currently in service would remain in service through the opening year. The temporary WTC PATH station was designed and constructed with the primary objective of restoring PATH service to Lower Manhattan as quickly as possible following September 11, 2001. Thus, its capacity, functionality, and equipment are limited over time, but its systems could support the anticipated opening year ridership.

PREFERRED ALTERNATIVE

The Preferred Alternative would consist of a track and platform level, a mezzanine/fare-zone level, and a street-level terminal building incorporating sub-grade pedestrian connections to adjacent streets, NYCT subways, and on- and off-site developments. The PATH tunnels, tracks, platforms, and mezzanine would be located within the WTC "bathtub" as they were prior to September 11, 2001.

The Preferred Alternative is being planned to support the PATH's system-wide improvements identified above, PATH's operating requirements, and future ridership demand. Each of these factors results in specific requirements for the design of the Terminal's platforms and tracks, and as such, it has been determined that a 5-track, 4-platform station is needed. Further details on the selection of 5-track, 4-platform configuration as well as alternative track and platform schemes evaluated in conjunction with project planning are provided in Appendix C.

System-Wide Improvements

PATH will implement improvements to increase capacity on trains operating between Newark and the WTC, by increasing their length from 8 to 10 cars. Not only will this improvement require that the WTC Terminal support 10-car operations but a consequence will be that more people will use the WTC PATH Terminal's platforms during peak travel periods.

All new PATH cars will have 3-doors per side allowing PATH to retire the portions of its current fleet with 2-doors per side. Three-door cars will decrease the boarding/alighting times of trains by 50 percent, which will improve dwell times at intermediate stations along the PATH route and could reduce the overall run time of trains. However, the new cars are not expected to improve the platform clearance time for passengers since they will not directly affect platform area or the provision or operation of stairways and escalators.

While PATH currently maintains 3-minute headways on its Newark-WTC Line and 4-minute headways on its Hoboken-WTC Line during portions of the peak hour, CBTC will facilitate such headways over a longer period with greater reliability and less potential for delays. CBTC in conjunction with the 10-car train program will have the ability to increase the throughput of the

PATH system, resulting in more passengers and a higher frequency of service at the WTC Terminal than before September 11, 2001. As such, platforms at the WTC Terminal will need to clear more swiftly in the future in order to maintain safe and efficient operations.

Operational Requirements

PATH must plan for failure management to maintain reliable, on-time peak period service. Because the WTC is a terminal station, trains dwell for short periods to maintain the operating schedule. Thus, to maintain the headway and allow for the arrival of a subsequent train, PATH requires two tracks for each the Hoboken-WTC and Newark-WTC Lines. In the event that a train becomes disabled, a fifth track is needed. The fifth track allows the disabled train to remain in the Terminal while the remaining four actives tracks can be used to continue service.

PATH has limited capacity for train storage at its Newark, Harrison, and Journal Square Yards. Therefore, PATH would use the WTC Terminal for the overnight storage of 6 Hoboken-WTC trains. Four tracks are required for this overnight storage and a 5th track is needed for revenue service on the Newark-WTC Line. The overnight storage of Hoboken-WTC trains at the WTC Terminal would allow for a more efficient ramp-up to AM peak period revenue service and decreases the potential for weather-related delays on the Hoboken-WTC Line.

Ridership Requirements

A principal consideration for the planning of the Terminal is the ability of platforms to safely accommodate peak period ridership. Because PATH is primarily a commuter system, the platform design must accommodate both AM and PM peak patterns of travel.

In the AM peak hour, trains unload passengers to the platform who must then ascend to mezzanine level. For this condition, the principal design criterion is the targeted time period within which all passengers exiting a train alight from the platform. As stairways and escalators become congested, passengers queue at the foot before they can ascend. Therefore, to avoid a lengthening of this back-up, it is important that all passengers clear the platform before arrival of the next train. The *Transit Capacity and Quality of Service Manual* states that a platform (and vertical circulation) should be planned to ensure full clearance of the platform before the next train arrives. However given that passengers may not use or may not be able to use all available exits, a safety factor of 20 to 30 percent is applied. Thus, a platform should clear fully within 70 to 80 percent of the scheduled headway.

The proposed frequency of Newark-WTC Line service requires that its platform clear within 126 to 144 seconds. However, based on projected ridership, a single Newark-WTC platform would require 213 seconds to clear. Thus, two Newark-WTC Line platforms are needed to meet platform clearance guidelines. A single Hoboken-WTC platform is sufficient to meet platform clearance criteria.

For the PM peak period, the planning of the platforms must also consider failure management in the event of a missed headway and subsequent delay in service. Thus, the platform must provide for adequate room to queue passengers waiting for the next arriving train.

Given ridership levels in 2025 and level of service standards, a minimum 15,264 square feet of platform area would be required for the Newark-WTC service in the event of a missed headway while 10,385 square feet would be required for the Hoboken-WTC service. However, accounting for the unusable areas of the platform (e.g., spaces occupied by escalators and elevators and the safety buffer along the platform edge), the Terminal's platforms would each provide for an

effective area of 10,416 square feet. Thus, a single platform would be adequate for the Hoboken-WTC Line but more than one platform would be needed for Newark-WTC Line.

In order to maintain temporary PATH service during construction of the Preferred Alternative, PANYNJ would not relocate the existing PATH tracks. As such, Platform A cannot be widened beyond its current configuration, which is not adequate for normal revenue service. Since three full-size platforms are needed for peak period service, the Preferred Alternative would include a total of 4 Platforms. The 5 tracks that are currently part of the temporary station would be retained in their current alignment, which is adequate to meet PATH's operating requirements.

The platform and mezzanine levels would have a north-south orientation and would be located immediately west of NYCT's 1 and 9 train tunnel and the proposed Greenwich Street extension. The four platforms would be long enough to accommodate 10-car trains in accordance with PATH's long-range goal to increase the operational capacity of the system, and five tracks will allow for increased queuing capacity during peak periods. Fare equipment would be located on the mezzanine level. The platforms and mezzanine would be fully enclosed with heating, air conditioning, and advanced communication and security systems.

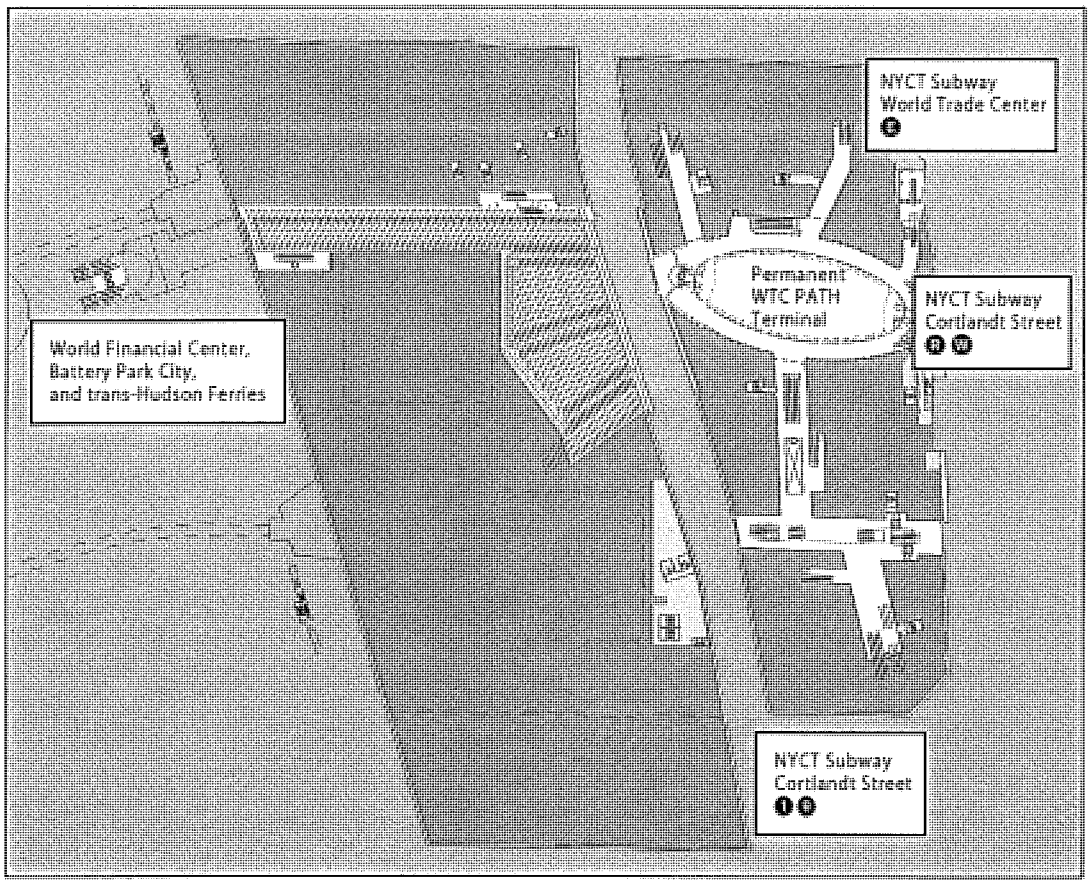
The concourse and street-level terminal building would be located on the eastern section of the WTC site extending from Greenwich to Church Streets. The mezzanine and lower concourse levels would connect via a passage under the NYCT's 1 and 9 train tunnel and over to the western side of the site. The concourse would have pedestrian passageways to the north, south, and west. The west passageway would cross beneath Route 9A to the World Financial Center. These passageways would also provide access to the proposed towers on the WTC site.

As shown in Figure 8A-3, the concourse level would also provide access to NYCT's Cortlandt Street Station on the 1 and 9, and R and W lines; the WTC Station on the E line; the existing corridor to One Liberty Plaza; and street-level at the intersections of Fulton and Greenwich Streets and Vesey and Church Streets. The passageway to the R and W Cortlandt Street Station would also link with the proposed pedestrian connection to the Fulton Street Transit Center. All circulatory elements within the Permanent WTC PATH Terminal would be designed to fully accommodate the expected volumes of passengers through its 2025 design year, with passenger corridors varying in width between 10 and 30 feet, and to comply with ADA requirements.

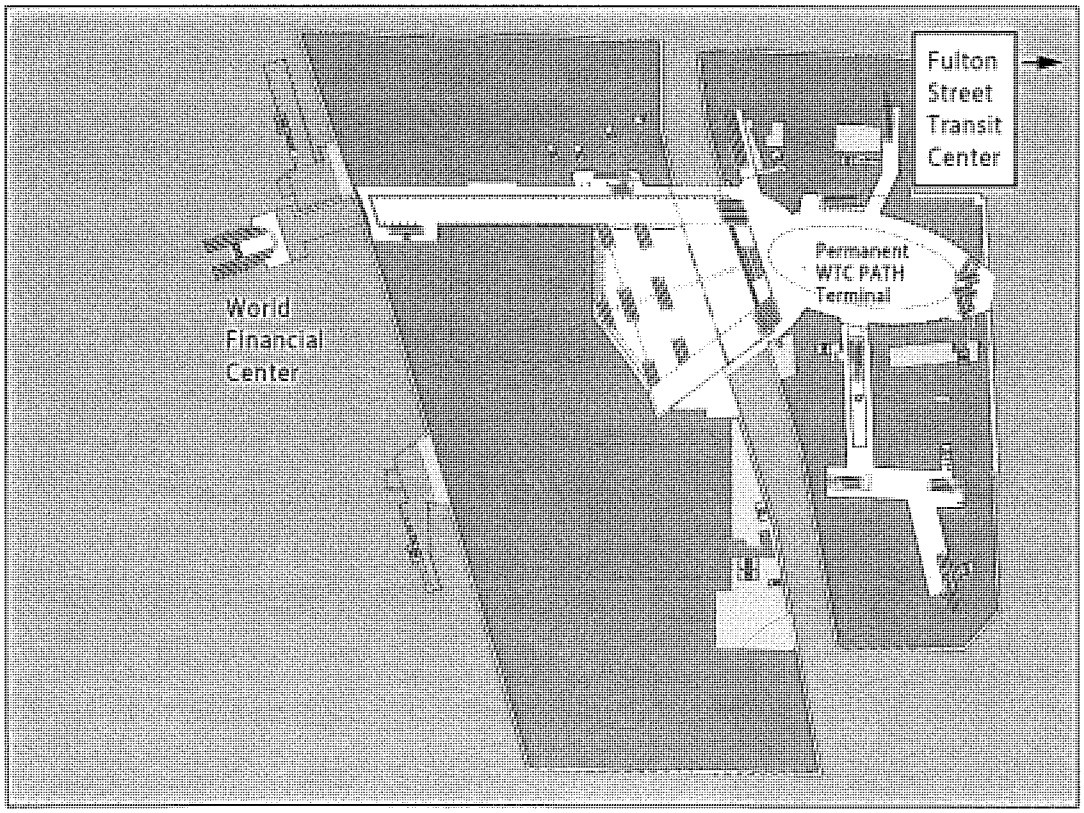
The Preferred Alternative would provide the PATH system with greater operational flexibility in meeting growing passenger demand over time. The new terminal itself would be able to accommodate larger passenger flows and reverse passenger flows than the original terminal or the current temporary WTC PATH station. It would also provide more convenient passenger connections to surrounding buildings, nearby NYCT subway stations, and trans-Hudson ferries. The Preferred Alternative is not expected to induce additional PATH ridership beyond the levels that would have existed had the events of September 11, 2001 not occurred, but it would be designed to accommodate passengers induced by the WTC redevelopment itself.

No impacts to PATH riders or its operations are expected once the Preferred Alternative is fully opened in 2009. Rather, the terminal would provide added passenger capacity that would be required given the redevelopment of the WTC site. The Preferred Alternative would accommodate elements that the temporary WTC PATH station could not, including pedestrian linkages to surrounding buildings, all area NYCT subways lines, and more convenient access to trans-Hudson ferries. Multiple entrances and exits would reduce walking times to access and egress the new terminal, which would lead to shorter walking distances and commute times for

3.14.05



Concourse Level (Balcony)



Concourse Level (Main)

Figure 8A-3

Pedestrian Connections

many users. Thus, any potential impacts of the Preferred Alternative to its users and to PATH operations would be beneficial.

DESIGN YEAR (2025)

FUTURE COMMON TO ALL ALTERNATIVES

In addition to the PATH system improvements described above under "Construction Period", PANYNJ is considering extending the PATH system from its current terminal at Newark Penn Station to connect with the Newark Liberty International Airport AirTrain rail system. When constructed, PATH would provide a direct rail connection between Lower Manhattan and the airport. The Newark Liberty International Airport extension will be undertaken independent of the Preferred Alternative.

As shown in Table 8A-7, by the design year, average weekday PATH usage to the WTC site is projected to be 167,718, an increase of 13.6 percent from 2000 levels. The AM peak hour usage is estimated to be 29,001, which is a 9 percent increase over 2000 ridership (see Appendix C).

Table 8A-7
PATH Ridership Forecast for WTC Service in the Design Year (2025)

Year	Average Weekday Trips			AM Peak Hour		
	Terminal Users	Weekday Boardings	Weekday Alightings	Terminal Users	Weekday Boardings	Weekday Alightings
2000	142,300	67,000	75,300	26,604	4,107	22,497
2025	161,718	76,143	85,575	29,001	5,660	23,341

Absent a Preferred Alternative, those demanding trans-Hudson service to and from the WTC site may be diverted to other modes of travel as the temporary WTC PATH stations nears or exceeds in reasonable capacity. However, for analysis purposes, it is assumed that these trips would continue to be made in some capacity.

NO ACTION ALTERNATIVE

Under the No Action Alternative, PATH service to Lower Manhattan would be eliminated by the design year since the temporary station would exceed its useful life. Over 162,000 weekday passengers who would have used the Permanent WTC PATH Terminal in year 2025 would be required to divert to alternate modes of transportation to access Lower Manhattan. These passenger diversions would require a more expensive and time-consuming commute for PATH riders and may involve additional transfers. Adverse impacts on vehicular traffic, other transit services, and the pedestrian network in the area are addressed in subsequent sections of this chapter.

Fifteen percent of PATH passengers who would have used the Permanent WTC Terminal if it were available would still use PATH as one leg of a multi-modal commute to Lower Manhattan. These passengers would instead use the Christopher Street or 9th Street PATH Station and then either walk or transfer to the NYCT subway. In year 2025, 24,258 total passengers would be diverted to these two stations each weekday, and 4,350 passengers would be diverted during the AM peak hour. It is anticipated that each station would attract half of these riders. Although both stations will have been renovated to include an additional exit/entrance than exist today, the

addition of almost 2,200 passengers to each of these stations during the AM peak hour would substantially impact the safe and efficient operation of each station.

PREFERRED ALTERNATIVE

No impacts to PATH riders or its operations are expected in 2025, the design year for the Preferred Alternative, if the terminal is constructed. Rather, the terminal would provide added passenger capacity that would be required given the completed redevelopment of the WTC site. The Preferred Alternative would accommodate elements that the temporary WTC PATH station could not, including pedestrian linkages to surrounding buildings, all area NYCT subways lines, and more convenient access to trans-Hudson ferries. Multiple entrances and exits would reduce walking times to access and egress the new terminal, which would lead to shorter walking distances and commute times for many users. Thus, any potential impacts of the Preferred Alternative to its users and to PATH operations would be beneficial.

E. MITIGATION

The Preferred Alternative would have positive benefits to PATH system operations and the convenience of its passengers. Since the Preferred Alternative would not adversely impact PATH operations, mitigation is not required. ✳

A. INTRODUCTION

This section of Chapter 8 describes vehicular traffic and parking conditions in the area and assesses whether the Preferred Alternative for a Permanent World Trade Center (WTC) PATH Terminal would be expected to create adverse impacts. The analyses that follow provide an overview of existing conditions, both before the events of September 11, 2001 and post-September 11, 2001 (i.e., current conditions) to establish a baseline from which future conditions are developed.

The traffic analyses focus on a study area and representative intersections at which adverse impacts could occur during construction of the Preferred Alternative. Adverse impacts are not expected once the Terminal is operational. The Port Authority of New York and New Jersey (PANYNJ) surveys indicate that PATH service does not generate a substantial level of connecting trips by either auto or taxi. The original PATH Terminal that was destroyed on September 11, 2001 generated a minimal volume of auto and taxi trips—just 1 percent of connecting trips to or from PATH were made by auto and less than ½ percent were made by taxi. With no new or induced riders directly resulting from the proposed Terminal, as compared to pre-September 11, 2001 projections, new auto and taxi trips are not expected. There is potential for the Terminal to create impacts resulting from construction vehicles traveling to and from the site. However, the analyses described below indicate that the volume of construction-related traffic is very low and has a limited potential for impacts that would require mitigation. There would be an adverse impact at only one location—Route 9A and Liberty Street in the PM peak hour—which can be mitigated via signal timing changes.

The parking analyses provide a summary of parking facilities in the area—either to accommodate construction staff who might drive to the area (although the vast majority can be expected to use public transportation) and potential impacts on blocks along which on-street parking may be prohibited to accommodate construction work zones or to facilitate the movement of vehicles into or out of the area during construction.

Additional data pertaining to the discussion that follows is presented in Appendix C of this Environmental Impact Statement (EIS).

B. METHODOLOGY

The analyses begin with a presentation of traffic and parking conditions pre- and post-September 11, 2001 based on available traffic data accumulated as part of several ongoing transportation and redevelopment proposals in Lower Manhattan, including the WTC Memorial and Redevelopment Plan and Fulton Street Transit Center. Future baseline (i.e., No Build) conditions are presented based on background traffic growth in the area and using analysis assumptions developed for other Lower Manhattan projects. Future Build conditions during construction of the Preferred Alternative were established based on current plans and estimates provided by

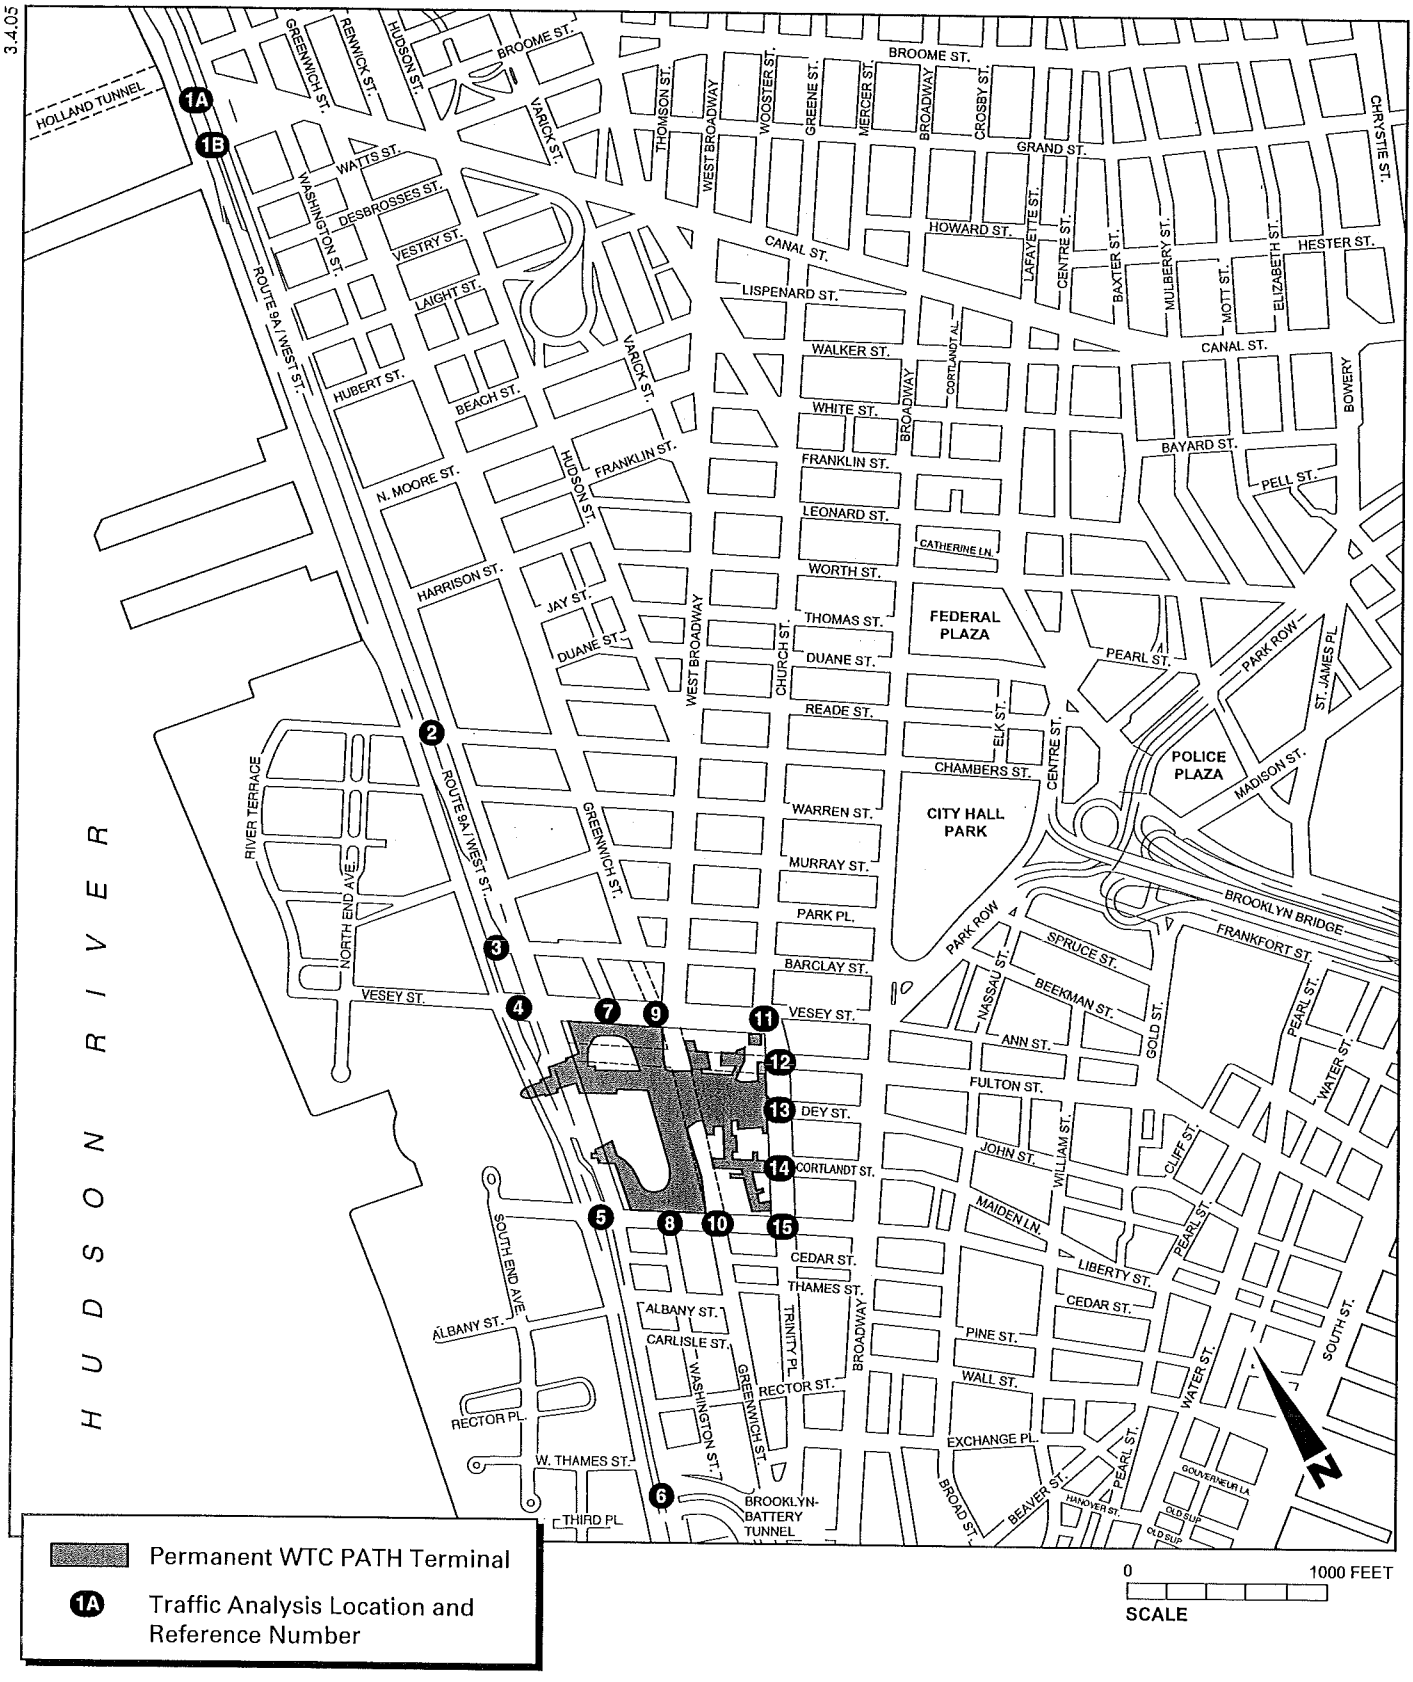
PANYNJ—projections of construction vehicles, construction employees, days and hours of construction activity, and currently anticipated street and/or lane closures to safely complete construction of the Terminal and facilitate the flow of traffic in the area. As noted above, the cumulative effects of PATH and other Lower Manhattan recovery projects construction is addressed in Chapter 15, "Cumulative Effects."

The traffic study area and analysis locations focus on the perimeter of the Project Site and on other intersections away from the site through which construction vehicles are expected to pass. These include key intersections along Route 9A leading to and from the Holland Tunnel (for trips to and from New Jersey) and the Brooklyn-Battery Tunnel (for trips to and from Brooklyn and Staten Island), and along Church Street and Broadway (for trips that could be made to/from parts of Brooklyn, Queens, Long Island, the Bronx, or Westchester). Commercial vehicle/truck traffic is not permitted on several major arterial roadways and bridges in the area, such as the FDR Drive, the Henry Hudson Parkway (Route 9A north of 57th Street), and the Brooklyn Bridge, and it is therefore expected that the vast majority of construction vehicle activity will approach and leave the Project Site via Route 9A en route to the Holland Tunnel and the Brooklyn-Battery Tunnel (BBT).

Eighteen intersections were initially considered for analysis as the traffic study area. These locations, which are listed below, were considered to represent key intersections where project-generated impacts may occur.

- Route 9A and Canal Street
- Route 9A and Chambers Street
- Route 9A and Barclay Street
- Route 9A and Vesey Street
- Route 9A and Liberty Street
- Route 9A and the BBT entrance/exit
- Washington Street and Vesey Street
- Greenwich Street/West Broadway and Vesey Street
- Church Street and Vesey Street
- Washington Street and Liberty Street
- Greenwich Street and Liberty Street
- Church Street and Liberty Street
- Church Street and Fulton Street
- Church Street and Dey Street
- Church Street and Cortlandt Street
- West Broadway and Chambers Street
- Broadway and Canal Street
- Broadway and the Bowery

The construction vehicle traffic assignment determined that a very minimal amount of traffic would pass through the West Broadway/Chambers Street, Broadway/Canal Street, and Broadway/Bowery intersections (two construction vehicles or less in each of the peak hours), so conditions at these intersections have not been analyzed since it is unlikely that they would be adversely impacted. Therefore, the remaining 15 intersections, shown in Figure 8B-1, comprise the traffic study area and were the focus of quantitative levels of service that follow later in this section.



PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure 8B-1
Traffic Analysis Locations

The analysis of traffic conditions is based on level of service (LOS) criteria defined for signalized intersections in the *2000 Highway Capacity Manual (HCM)*:

- LOS A describes operations with very low delays, i.e., 10.0 seconds or less per vehicle. This occurs when signal progression is extremely favorable and most vehicles arrive during the green phase. Most vehicles do not stop at all.
- LOS B describes operations with delays in the range of 10.1 to 20.0 seconds per vehicle. This generally occurs with good progression and/or short cycle lengths. Again, most vehicles do not stop at the intersection.
- LOS C describes operations with delays in the range of 20.1 to 35.0 seconds per vehicle. These higher delays may result from fair progression and/or longer cycle lengths. The number of vehicles stopping is noticeable at this level, although many still pass through the intersection without stopping.
- LOS D describes operations with delays in the range of 35.1 to 55.0 seconds per vehicle. At LOS D, the influence of congestion becomes more noticeable. Longer delays may result from some combination of unfavorable progression, long cycle lengths, or high volume-to-capacity (v/c) ratios. Many vehicles stop, and the proportion of vehicles not stopping declines.
- LOS E describes operations with delays in the range of 55.1 to 80.0 seconds per vehicle. This is considered to be the limit of acceptable delay. These high delay values generally indicate poor progression, long cycle lengths, and high v/c ratios.
- LOS F describes operations with delays in excess of 80.0 seconds per vehicle. This is considered to be unacceptable to most drivers. This condition often occurs with oversaturation, i.e., when arrival flow rates exceed the capacity of the intersection. It may also occur at high v/c ratios with cycle failures. Poor progression and long cycle lengths may also be contribute to such delays. Often, vehicles do not pass through the intersection in one signal cycle.

Based on guidance in the *New York City Environmental Quality Review Technical Manual*, in New York City, LOSs A, B, and C are considered acceptable, LOS D is generally considered marginally acceptable up to mid-LOS D (45 seconds of delay for signalized intersections) and unacceptable above mid-LOS D, and LOS E and F indicate congestion.

For unsignalized intersections (such as Route 9A and Barclay Street), delay is defined as the total elapsed time from when a vehicle stops at the end of the queue until the vehicle departs from the Stop line: LOS A describes operations with very low delay, i.e., 10.0 seconds or less per vehicle; LOS B describes operations with delays in the range of 10.1 to 15.0 seconds; LOS C has delays in the range of 15.1 to 25.0 seconds; LOS D, 25.1 to 35.0 seconds per vehicle; and LOS E, 35.1 to 50.0 seconds per vehicle, which is considered to be the limit of acceptable delay. LOS F describes operation with delays in excess of 50.0 seconds per vehicle, which is considered problematic to most drivers. This condition exists when there are insufficient gaps of suitable duration to allow side street traffic to cross safely through a major vehicular traffic stream.

The definition of an adverse traffic impacts is based on the following criteria, which have been used for other major transportation improvement projects such as this (e.g., the Second Avenue Subway): deterioration in level of service from below mid-LOS D (less than 45 seconds of

delay) to above mid-LOS D (greater than 45 seconds of delay) or to LOS E or F as long as the increase in delay is 10 seconds or more; deterioration from LOS E to LOS F, or within LOS E or within LOS F, as long as the increase in delay is 10 seconds or more.

Since the Preferred Alternative is not expected to induce new PATH ridership nor new vehicular traffic, detailed analyses were not needed to conclude that there would be no traffic impacts in the 2009 opening and 2025 design years, which is documented in this section of the EIS. However, detailed traffic level of service analyses are presented for the year 2006 peak construction condition. A No Action Alternative without PATH service to the WTC site, on the other hand, would result in substantial increases in vehicular traffic in Lower Manhattan.

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

PRE-SEPTEMBER 11, 2001 BASELINE CONDITIONS

STREET NETWORK AND TRAFFIC VOLUMES

The study area and most of Lower Manhattan's street network follow a grid pattern that is typical of most of Manhattan. The major north-south roadways in the area include Route 9A which is two-way, and Church Street and Broadway, which function as a one-way pair (Church Street northbound, Broadway southbound). Each of these north-south roadways carries several traffic lanes and possesses substantial capacity. The east-west roadways in the area have more limited traffic-carrying capacity. These roadways include Chambers Street, which is two-directional, carrying one to two lanes of traffic per direction; Vesey Street, which is two-way (when open before the events of September 11, 2001) between Route 9A on the west and Church Street on the east and generally carrying two traffic lanes per direction; and one-way eastbound between Church Street and Broadway with generally two moving lanes (sometimes three) of traffic although three striped lanes exist. South of the Project Site, Liberty Street was the primary east-west street. Pre-September 11, 2001, Liberty Street served as a primarily eastbound street with two to three lanes of traffic, and also included a westbound "service road" around the southern periphery of the WTC site.

Route 9A is the major traffic carrier in the area with the predominant traffic flows being northbound in the morning and southbound in the evening. In the AM peak hour, northbound Route 9A carried approximately 3,200 vehicles per hour (vph) at Liberty Street and 2,800 vph at Vesey Street, and about 2,150 vph southbound at Vesey Street and 2,350 vph at Liberty Street. During the midday peak hour, northbound volumes were about 2,200 vph at Liberty Street and 2,050 vph at Vesey Street, while southbound volumes were approximately 1,800 vph at Vesey Street and 2,000 vph at Liberty Street. During the PM peak hour, northbound volumes were about 2,250 to 2,300 vph at both locations, and southbound volumes were about 2,400 vph at Vesey Street and 2,850 vph at Liberty Street. Route 9A carries both through traffic that bypasses the area and local traffic destined to the WTC vicinity and Lower Manhattan.

Other than Route 9A, Trinity Place/Church Street is the major northbound traffic route in the western half of Lower Manhattan. Pre-September 11, 2001, traffic volumes were generally about 1,250 vph in the AM peak hour at Liberty Street and 1,850 vph farther north at Vesey Street. Midday peak hour volumes were considerably lower, about 950 vph at Liberty Street and 1,400 vph at Vesey Street. PM peak hour volumes were about 900 vph at Liberty Street and 1,500 vph at Vesey Street.

Broadway is the southbound counterpart to Church Street, carrying generally two to four moving lanes. Before September 11, 2001, AM peak hour traffic volumes were generally about 1,400 vph at Vesey Street and 1,000 vph at Liberty Street. Midday peak hour volumes were approximately 1,200 vph at Vesey Street and 900 vph at Liberty Street, while PM peak hour volumes were generally 1,500 vph at Vesey Street and 850 vph at Liberty Street.

Before the terrorist attacks of September 11, 2001, Vesey Street operated two ways between Battery Park City/World Financial Center and Church Street, and one-way eastbound east of Church Street. Pre-September 11, 2001, eastbound Vesey Street carried about 900 vph approaching Church Street; in the midday, it carried about 500 vph, and in the PM peak hour, it carried about 350 vph at this location. Westbound volumes were generally about 400 to 450 vph approaching Route 9A.

Detailed traffic volume data are provided in Appendix C. These volumes were developed by several state and local agencies, including PANYNJ, Lower Manhattan Development Corporation (LMDC), New York Metropolitan Transportation Council (NYMTC), New York State Department of Transportation (NYSDOT), Metropolitan Transportation Authority (MTA), the New York City Department of Transportation (NYCDOT), and the New York City Department of City Planning (NYCDCP). Working cooperatively as part of the Lower Manhattan Working Group, their efforts focused on the range of major transportation projects proposed and being studied in Lower Manhattan to ensure that all of the Lower Manhattan recovery projects use a consistent set of baseline traffic volumes for their individual analyses.

TRAFFIC LEVELS OF SERVICE

Each of the intersections defined previously as analysis locations were analyzed using *2000 HCM* procedures. For pre-September 11, 2001 conditions, Table 8B-1 presents an overview of the "existing" levels of service, showing each intersection's "overall" level of service for signalized intersections (the overall intersection LOS is a weighted average of all of the individual traffic movements); for the unsignalized Route 9A/Barclay Street intersection, the critical traffic movement's level of service is shown. Detailed intersection-by-intersection level of service data is provided in Appendix C.

As shown above, the majority of the intersections being studied operated at overall acceptable levels of service, with the notable exception of the intersection of Route 9A at the entrance/exit of the BBT. Even though the "overall" intersection levels of service are generally acceptable, several specific traffic movements operated at congested levels of service E or F (i.e., westbound Vesey Street approaching Route 9A during all three traffic analysis hours, southbound left turns from Route 9A onto Liberty Street during all three traffic analysis hours, and a select number of others). Detailed traffic level of service summaries are presented in Appendix C.

PARKING

An inventory of pre-September 11, 2001 public parking facilities was conducted as part of the PANYNJ and LMDC's *Lower Manhattan Transportation Report Phase One* in early- to-mid-2002. The information presented here is primarily taken from that report and from work being conducted as part of LMDC's *World Trade Center Memorial and Redevelopment Plan Generic Environmental Impact Statement (GEIS).*

Table 8B-1
Pre-September 11, 2001 Conditions: Intersection Levels of Service

Intersection	Ref. No.	AM Peak Hour	Midday Peak Hour	PM Peak Hour
Route 9A and Canal Street	1A/1B	C	B	E
Route 9A and Chambers Street	2	C	C	D
Route 9A and Barclay Street (critical approach)	3	C	C	C
Route 9A and Vesey Street	4	D	D	D
Route 9A and Liberty Street	5	D	C	C
Route 9A and BBT Entrance/Exit	6	F	F	F
Washington Street and Vesey Street	7	A	A	A
Washington Street and Liberty Street	8	A	A	A
Greenwich Street/West Broadway and Vesey Street	9	D	B	C
Greenwich Street and Liberty Street	10	B	A	B
Church Street and Vesey Street	11	C	D	D
Church Street and Fulton Street	12	B	B	B
Church Street and Dey Street	13	A	B	A
Church Street and Cortlandt Street	14	C	B	B
Church Street and Liberty Street	15	B	B	B

Note: Refer to Figure 8B-1.

Prior to the events of September 11, 2001, there were 20 identified off-street parking facilities within ¼ mile of the WTC containing over 7,000 spaces, and an additional 46 facilities between ¼ mile and ½ mile of the site with an additional 6,800 spaces. Occupancy of these spaces at midday, generally considered peak utilization time, was approximately 86 percent for the former and 90 percent for the latter.

Legal on-street parking is much more limited. Although data is not available for the entire area pre-September 11, 2001, post-September 11, 2001 surveys conducted for LMDC's *World Trade Center Memorial and Redevelopment Plan GEIS* indicate that within a ½-mile walking distance of the WTC site, occupancy of legal on-street spaces was 85 to 90 percent, or about one available space for every 11 blockfaces.

CHANGES IN THE AFFECTED ENVIRONMENT SINCE SEPTEMBER 11, 2001

STREET NETWORK AND TRAFFIC VOLUMES

Traffic volumes in Lower Manhattan have generally decreased by about 20 percent since September 11, 2001. However, this areawide overview does not mean that such decreases have occurred uniformly throughout Lower Manhattan or that all streets have experienced lower volumes. For example, due to the closures of Vesey and Liberty Streets near the WTC site, which previously enabled traffic to proceed from Route 9A to streets more centrally located within Lower Manhattan, some traffic has diverted from Route 9A to Broadway, thus increasing Broadway's traffic volumes over its pre-September 11, 2001 levels. An overview of general traffic volumes on some of the area's major streets follows and detailed volumes are provided in Appendix C.

Route 9A remains the major traffic carrier in the area with the predominant traffic flows still being northbound in the morning and southbound in the evening. In the AM peak hour, northbound Route 9A carries approximately 2,450 vph at Liberty and Vesey Streets, and about 1,850 vph southbound at both of these cross-street locations, which is considerably lower than pre-September 11, 2001 volumes. During the midday peak hour, northbound volumes are 1,650 vph at both Liberty and Vesey Streets, while southbound volumes are approximately 1,550 to 1,600 vph at both locations, also considerably lower than before September 11, 2001. During the PM peak hour, northbound volumes are 1,900 to 1,950 vph at both locations, and southbound volumes are 2,300 to 2,350 vph at the two cross-street locations, with just the northbound volume being considerably lower.

Northbound Trinity Place/Church Street traffic volumes are generally about 750 vph in the AM peak hour at Liberty Street and 1,100 vph farther north at Vesey Street, about two-thirds their levels pre-September 11, 2001. Midday peak hour volumes are similar to AM levels, with approximately 650 vph at Liberty Street and 1,050 vph at Vesey Street. PM peak hour volumes are 500 vph at Liberty Street and 800 vph at Vesey Street, just over half of their pre-September 11, 2001 levels.

Broadway is the southbound counterpart to Church Street. Post-September 11, 2001, AM peak hour traffic volumes are generally about 1,650 vph at Vesey Street and 1,000 vph at Liberty Street. Midday peak hour volumes are approximately 1,300 vph at Vesey Street and 700 vph at Liberty Street. PM peak hour volumes are generally about 1,350 vph at Vesey Street and 600 vph at Liberty Street.

Before September 11, 2001, Vesey Street operated as an east-west connector street between Route 9A and interior destinations in Lower Manhattan. However, Vesey Street is currently closed to regular vehicle traffic between Route 9A and Church Street.

Peak hour traffic volumes at representative locations are presented in Appendix C. These volumes were also developed by several local and state agencies working cooperatively as part of the Lower Manhattan Working Group on the range of major transportation projects proposed and being studied in Lower Manhattan, as described above.

TRAFFIC LEVELS OF SERVICE

Table 8B-2 presents an overview of the post-September 11, 2001 traffic levels of service, showing each signalized intersection's "overall" level of service (again, the overall intersection LOS is a weighted average of all the individual traffic movements); for the unsignalized Route 9A/Barclay Street intersection, the critical traffic movement's level of service is shown. Detailed intersection-by-intersection level of service data is provided in Appendix C.

The majority of the analysis locations continue to operate at overall acceptable levels of service. The notable exception of the intersection of Route 9A at the entrance/exit of the BBT, as was also true prior to September 11, 2001. Even though the "overall" intersection levels of service are generally acceptable, several specific traffic movements operate at unacceptable levels of service E or F (i.e., northbound left turns from Route 9A onto Liberty Street into the Battery Park City area during all three traffic analysis hours, and a select number of others). Detailed traffic level of service summaries are presented in the Appendix C.

Table 8B-2
Comparison of Pre- and Post-September 11, 2001 Intersection Levels of Service

Intersection	Ref. No.	AM Peak Hour		Midday Peak Hour		PM Peak Hour	
		Pre-Sep 11	Post-Sep 11	Pre-Sep 11	Post-Sep 11	Pre-Sep 11	Post-Sep 11
Route 9A and Canal Street	1A/ 1B	C	C	B	B	E	B
Route 9A and Chambers Street	2	C	C	C	B	D	C
Route 9A and Barclay Street	3	C	N/A	C	N/A	C	N/A
Route 9A and Vesey Street	4	D	F	D	D	D	D
Route 9A and Liberty Street	5	D	C	C	B	C	D
Route 9A and BBT Entrance/Exit	6	F	F	F	F	F	F
Washington Street and Vesey Street	7	A	N/A	A	N/A	A	N/A
Washington Street and Liberty Street	8	A	N/A	A	N/A	A	N/A

Church Street and Cortlandt Street	14	C	A	B	B	B	B
Church Street and Liberty Street	15	B	A	B	A	B	A

Note: Refer to Figure 8B-1

PARKING

An inventory of current parking conditions was conducted as part of LMDC's *World Trade Center Memorial and Redevelopment Plan GEIS* in September 2003 for all off-street public parking facilities within ¼ mile and ½ mile radii of the WTC site.

There are 19 off-street parking facilities within ¼ mile of the WTC site containing close to 5,150 spaces, and an additional 48 facilities between ¼ mile and ½ mile of the site with an additional 8,000 spaces. The surveyed occupancy of these spaces at midday was approximately 82 percent for the former and 55 percent for the latter. This 55 percent level includes the 2,000-space parking garage at 2 Morris Street which is currently closed. When this facility is not accounted for, there are 6,000 spaces available within ¼ mile and ½ mile from the WTC site, with an overall midday utilization of about 73 percent.

Legal on-street parking is very limited. Surveys conducted for LMDC indicate that within a ½-mile walking distance of the WTC site, occupancy of legal on-street spaces was 85 to 90 percent, or about one unoccupied space for every 11 blockfaces.

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

This section addresses the potential for adverse traffic impacts for three analysis years—the construction year, the opening year, and the design year for the Permanent WTC PATH Terminal. As stated previously, the Terminal is not expected to induce new riders as compared to pre-September 11, 2001 forecasts. Furthermore, new riders to the system would be attributed

to residential and commercial development in the area rather than to the operation of the Preferred Alternative.

CONSTRUCTION PERIOD (2006)

FUTURE COMMON TO ALL ALTERNATIVES

The detailed construction year analyses were conducted for several Lower Manhattan projects (i.e., the Fulton Street Transit Center, South Ferry Terminal, Route 9A Project, and the World Trade Center Memorial and Redevelopment Plan). The anticipated traffic levels of service at the 15 traffic study area intersections are shown in Table 8B-3 below. These analyses assume that Liberty and Vesey Streets remain closed to through traffic in 2006. The operation of other area streets was assumed to be the same as today.

Table 8B-3
2006 No Action Alternative: Intersection Levels of Service

Intersection	Ref. No.	AM Peak Hour	Midday Peak Hour	PM Peak Hour
Route 9A and Canal Street	1A/1B	C	C	C
Route 9A and Chambers Street	2	C	B	C
Route 9A and Barclay Street (critical approach)	3	C	B	B
Route 9A and Vesey Street	4	F	E	E
Route 9A and Liberty Street	5	A	A	B
Route 9A and BBT Entrance/Exit	6	F	F	F
Washington Street and Vesey Street	7	NA	NA	NA
Washington Street and Liberty Street	8	NA	NA	NA
Greenwich Street/West Broadway and Vesey Street	9	NA	NA	NA
Greenwich Street and Liberty Street	10	NA	NA	NA
Church Street and Vesey Street	11	B	B	A
Church Street and Fulton Street	12	C	C	B
Church Street and Dey Street	13	B	B	A
Church Street and Cortlandt Street	14	C	D	C
Church Street and Liberty Street	15	B	A	A

Note: NA = Not applicable; closed for construction or security reasons.

The findings of these analyses show that there would be some modest change in traffic conditions as compared to 2003. The results shown in Table 8B-3 represent the baseline against which potential impacts of construction vehicles generated by the Preferred Alternative is compared.

NO ACTION ALTERNATIVE

Since the No Action Alternative itself would not generate construction period traffic, this alternative would not result in any adverse traffic impacts during the construction period.

PREFERRED ALTERNATIVE

The Preferred Alternative would generate approximately 15 construction vehicles in each of the weekday peak hours, with a relatively even distribution of incoming and outgoing traffic. (Refer to Chapter 3, "Construction Methods and Materials," for a description of the volumes and hours of the day.)

The projected construction vehicle trips were assigned to the traffic study area's streets, as shown in Figure 8B-2. The results show that a relatively modest volume of construction vehicles are expected to pass through the various intersections being analyzed in the area, ranging from three to 15 vehicles, with no more than seven expected on any one approach, which is a very modest increase.

Traffic levels of service were analyzed with the addition of these construction vehicles, and the resulting overall intersection levels of service are shown in Tables 8B-4 through 8B-6 (detailed level of service findings for each traffic movement at each analysis location are provided in Appendix C). The overall intersection level of service is presented below for signalized intersections; for the unsignalized intersection of Route 9A and Barclay Street, the critical traffic movement's level of service is shown.

Table 8B-4
2006 No Action and Preferred Alternatives:
AM Peak Hour Intersection Levels of Service

Intersection	Ref. No.	2006 No Action	2006 Preferred Alternative	Required Mitigation
Route 9A and Canal Street	1A/1B	C	C	None
Route 9A and Chambers Street	2	C	C	None
Route 9A and Barclay Street (critical approach)	3	C	C	None
Route 9A and Vesey Street	4	F	F	None
Route 9A and Liberty Street	5	A	A	None
Route 9A and BBT Entrance/Exit	6	D	D	None
Washington Street and Vesey Street	7	NA	NA	None
Washington Street and Liberty Street	8	NA	NA	None
Greenwich Street/West Broadway and Vesey Street	9	NA	NA	None
Greenwich Street and Liberty Street	10	NA	NA	None
Church Street and Vesey Street	11	B	B	None
Church Street and Fulton Street	12	C	C	None
Church Street and Dey Street	13	B	B	None
Church Street and Cortlandt Street	14	C	C	None
Church Street and Liberty Street	15	B	B	None

Note: NA = Not applicable; closed for construction or security reasons.

There would be no impacts requiring mitigation in the AM or midday traffic analysis hours. In the PM peak hour, there would be an impact at one location—Route 9A and Liberty Street. This impact would occur due to increased delays to southbound traffic although the overall intersection is expected to operate at an acceptable level of service.

OPENING YEAR (2009)

FUTURE COMMON TO ALL ALTERNATIVES

By the opening year for the Permanent WTC PATH Terminal, it is expected that background conditions in Lower Manhattan will change as compared to today. As new development occurs on and around the WTC site, vehicular traffic and parking demand in Lower Manhattan will increase. However, the ongoing reconstruction of streets in Lower Manhattan and the infrastructure improvements planned with the WTC Memorial and Redevelopment Plan and the Route 9A Project will improve circulation in the immediate vicinity of the Project Site.

At present, LMDC, PANYJ, NYSDOT, and the New York City Department of Transportation are coordinating a circulation plan for new and existing streets in Lower Manhattan. This plan is expected to be implemented by 2009.

NO ACTION ALTERNATIVE

Under the No Action Alternative, PANYNJ would maintain the temporary WTC PATH station, and the Preferred Alternative itself would not generate vehicle trips. Therefore, the No Action Alternative would not result in traffic impacts in the opening year.

PREFERRED ALTERNATIVE

The Preferred Alternative would generate a minimal number of new vehicle trips since only approximately 1 percent of riders would transfer between PATH and automobiles and only ½ percent transfer between PATH and taxis (based on surveys conducted by PANYNJ before September 11, 2001. As described in the DEIS, a sub-grade concourse between the Permanent WTC PATH Terminal and Liberty Plaza Park, as was proposed in the Terminal with a Liberty Plaza Connection Alternative, would have improved traffic circulation at the intersection of Church and Liberty Streets. Although this connection is no longer proposed, the Preferred Alternative would not result in adverse changes in traffic conditions as compared to the No Action Alternative. Therefore, the Preferred Alternative is not expected to result in significant adverse traffic impacts in its opening year.

DESIGN YEAR (2025)

FUTURE COMMON TO ALL ALTERNATIVES

By 2025, all elements of the WTC Memorial and Redevelopment Plan will be completed as will the other private development currently planned in Lower Manhattan. The combined completion and occupation of these projects will increase traffic flows in Lower Manhattan. However, the capacity improvements that are planned as part of the transportation recovery efforts, including mitigation measures being proposed as part of the *World Trade Center Memorial and Redevelopment Plan Generic Environmental Impact Statement* should help to alleviate congestion as compared to the conditions that existed before September 11, 2001.

NO ACTION ALTERNATIVE

Because the temporary station would need to be retired from service, the 2025 No Action Alternative would result in former PATH riders who would drive to Lower Manhattan or use

commuter vans or express buses. The percentage diversion to these alternative modes is assumed to be the same for 2025 as cited above for the opening year.

Weekday, AM peak hour projections for year 2025 indicate that approximately 26,045 PATH riders would enter Lower Manhattan at the WTC Terminal and that approximately 4,510 would board PATH trains at the WTC Terminal for trips to New Jersey. Table 8B-7 presents the estimated volume of vehicle trips that would be made into and out of Lower Manhattan should there be no WTC PATH service.

Table 8B-7
2025 No Action Alternative: Projected Increase in AM Peak Hour Vehicle Trips from Diverted PATH Customers

Trips	Autos	Buses	Vans	Total
Inbound	866	109	26	1,001
Outbound	153	32	8	193
Total	1,019	141	34	1,194

Note: Assumes average occupancies of 1.5 persons per auto, 50 persons per bus, and 10 persons per van for inbound trips, and 1.5 persons per auto, 30 persons per bus, and 6 persons per van for "reverse commute" outbound trips in the AM peak hour.

As shown in Table 8B-7, it is estimated that under the No Action Alternative there would be 866 new auto trips into Lower Manhattan in the AM peak hour, 109 new bus trips, and 26 new commuter van trips, for a total of 1,001 new inbound trips under a worst case scenario with no PATH WTC service. It is estimated that there would be 153 new auto trips out from Lower Manhattan in the AM peak hour ("reverse commute" trips), 32 new bus trips, and 8 new commuter van trips, for a total of 193 new outbound trips. (As described above, lower vehicle occupancies were applied for reverse commuters). Overall, 1,194 new vehicular trips can be expected within Lower Manhattan during the AM peak hour, and a generally comparable volume in the PM peak hour although in the opposite direction.

The addition of approximately 1,200 additional vehicle trips in each of the peak hours in the Lower Manhattan area would represent an increase in traffic and possible adverse impacts at key locations, especially near the portals to the area such as the Holland Tunnel and possibly along the Route 9A corridor, as was noted above for year 2009 conditions. A projected increase of approximately 1,001 new inbound vehicle trips would represent approximately 25 percent of the Holland Tunnel's inbound capacity and a considerable percentage of its toll plaza capacity in New Jersey. Furthermore, increased travel delays would be expected at key Lower Manhattan locations under the No Action Alternative.

PREFERRED ALTERNATIVE

Since a Permanent WTC PATH Terminal would be operational under this alternative, traffic volumes in the study area would be substantially lower than in the No Action Alternative described above. As described in the DEIS, the Terminal with a Liberty Plaza Connection Alternative would have resulted in improved traffic circulation as compared to the Preferred Alternative. However, since the Preferred Alternative would generate far fewer vehicle trips than the No Action Alternative in the design year, it would not result in significant adverse traffic impacts.

E. MITIGATION

As described in Chapter 2, "Project Alternatives" and Chapter 3, "Construction Methods and Materials," PANYNJ has committed to Environmental Performance Commitments (EPCs) as part of their planning, design, and construction of the Preferred Alternative. Four EPCs specifically address potential construction period impacts to access and circulation. Table 8B-8 shows these EPCs and current plans for their implementation.

Table 8B-8
Environmental Performance Commitments

Proposed Commitment	Implementation Plan
Establish a project-specific pedestrian and vehicular maintenance and protection plan.	PANYNJ will develop a Maintenance and Protection of Traffic Plan (MPT) as part of their contract documents for the Preferred Alternative. A construction Traffic Management Plan (TMP) will also be developed for the Lower Manhattan Recovery Projects to address these issues in a broader sense. The TMP will be coordinated by PANYNJ, LMDC, MTA, NYSDOT, NYCDOT, the Lower Manhattan Construction Command Center, and others, as appropriate, based on updated construction scheduling and staging as the designs of individual projects are advanced.
Promote public awareness through mechanisms such as: a) signage; b) telephone hotline; and c) Web site updates.	The TMP will have a public outreach component to communicate traffic information, lane closures, access changes, and travel advisories for the duration of project construction.
Ensure sufficient alternate street, building, and station access during construction period.	For the Preferred Alternative, the MPT Plan included in the contract documents will be used to implement this EPC. The TMP will address the access issues for the Lower Manhattan Recovery Projects by coordinating the individual MPTs required and times for specific land uses and infrastructure (i.e. bus stops, transit stations, etc.).
Regular communication with New York City Department of Transportation and participation in its construction efforts.	PANYNJ will consult with NYCDOT to develop the MPT Plan for the Preferred Alternative. NYCDOT will be active in the development, update, and implementation of the TMP for the Lower Manhattan Recovery Projects.

Although the EPCs would help to reduce potential congestion and vehicular access problems during the construction period, project-generated vehicle trips would result in one construction period impact during the PM peak hour at the intersection of Route 9A and Liberty Street. A modest transfer of 5 seconds of green signal time from the Liberty Street approach to Route 9A would mitigate this adverse impact. PANYNJ will incorporate this mitigation into the Project's MPT Plan.

As described in the *Route 9A Project Draft Supplemental Environmental Impact Statement*, NYSDOT will lead in preparing a Traffic Management Plan (TMP) for the Lower Manhattan Recovery Projects. PANYNJ will coordinate with NYSDOT to ensure that the construction period traffic mitigation required for the Preferred Alternative is incorporated into the coordinated TMP. ✶

A. INTRODUCTION

This section discusses and describes the various public transportation services that were provided both pre- and post-September 11, 2001, the travel characteristics and volumes of public transportation users in and through the study area, and an analysis of effects of the No Action and Preferred Alternatives on the public transit network in the World Trade Center (WTC) area. The public transportation services that are described and analyzed in this section include New York City Transit (NYCT) subways, New Jersey Transit (NJ Transit) commuter rail, trans-Hudson ferries, and local and express bus service. Since PATH service was already described in Section 8A, it is not developed further in this section.

Public transit is the primary means of transportation to Lower Manhattan. Before September 11, 2001, the WTC was both a major trip generator and transit hub served by 11 NYCT subway lines (1, 2, 3, 4, 5, 9, A, C, E, N and R) and over five dozen bus lines, and was the terminus for two PATH train lines. In addition, almost 17,000 round-trip passengers prior to September 11, 2001 used trans-Hudson ferries within a few blocks of the WTC site.

The terrorist attacks radically altered the transit network in the WTC area. Most substantially, the terrorist attacks destroyed the WTC PATH Terminal and the Cortlandt Street Station on the 1 and 9 line, and forced the closing of the E line's WTC Station and the Cortlandt Street Station on the N and R line. It also destroyed the 1 and 9 subway tunnel traversing the WTC site, which prevented 1 and 9 local subway service south of Chambers Street and impacted both local and express service along the entire Seventh Avenue Line.

Without WTC/Lower Manhattan PATH service, many former PATH riders diverted primarily to one of three routes or travel modes:

- NJ Transit commuter rail to Penn Station-New York with a transfer to Lower Manhattan-bound NYCT subway service.
- Uptown-bound PATH trains to Christopher Street Station with a transfer to Lower Manhattan-bound NYCT subway or bus service.
- Trans-Hudson ferries.

The Preferred Alternative is not expected to induce PATH ridership beyond levels that would have occurred had the terrorist attacks not happened. Therefore, the Preferred Alternative would not generate additional ridership on NYCT subways, local or express bus service, NJ Transit commuter rail, or trans-Hudson ferries from transferring PATH riders.

In November 2003, the opening of the temporary WTC PATH station allowed for resumed PATH service to Lower Manhattan. The Preferred Alternative would replace and enhance the passenger capacity of the former WTC PATH Terminal destroyed on September 11, 2001 and the temporary WTC PATH station that was recently opened. In time, the demand for

transportation services would grow as the WTC site is redeveloped and other previously planned or anticipated development occurs in Lower Manhattan. A fully functioning PATH system would be a necessary component in the public transportation system and the overall transportation network for the region in order to accommodate increasing transit demand. As stated in the "Probable Impacts" section below, if the Preferred Alternative is not implemented, the operation of the overall transit network would be impacted. West-of-Hudson travelers would be especially affected as their commute would likely be more expensive and time-consuming, and may involve additional transfers when compared to their former PATH commute. It is anticipated that the No Action condition would result in travel patterns similar to those of the period between September 11, 2001 and the opening of the temporary PATH station. This analysis draws upon that period as a basis for assessing the No Action condition.

B. METHODOLOGY

The analyses begin with a description of transit services that were available both pre- and post-September 11, 2001. Transit services, including local/express buses, commuter rail, NYCT subways, and trans-Hudson ferries, are reviewed in terms of frequency and service area. Historical ridership data are also compared and analyzed. The current and historical, or "existing conditions," service and ridership information are then compared to the expected system operations and ridership once the Preferred Alternative would open in 2009, and to the Terminal's 2025 design year.

A line-haul analysis is included for NYCT subway lines operating in the WTC area, comparing the average passenger load of each subway car to its corresponding guideline and maximum capacities. The arrival load represents the volume on board as a train enters a station while the leave load compares the volume to the capacity of a train as it departs.

The evaluation of potential subway line-haul impacts indicates the extent to which crowding may occur. Generally, any increase in load levels that remains within the guideline capacity is not considered substantial. Projected increases to a build condition that exceeds guideline capacity may be considered adverse if the project generates five or more passengers per car.

Based on a comparison of PATH ridership estimates to pre-September 11, 2001 conditions, it is not anticipated that the Preferred Alternative would generate substantial new riders at subway stations or on local buses or ferries. Furthermore, the Preferred Alternative would generate fewer riders on these services than the No Action Alternative. Therefore, this chapter provides a qualitative assessment of the project's effects on subway station operations, local bus service, and ferries.

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

PRE-SEPTEMBER 11, 2001 BASELINE CONDITIONS

NYCT SUBWAY SERVICE

The majority of commuters accessing the WTC area used the NYCT subway system. Figure 8C-1 provides a pre-September 11, 2001 map of the NYCT subway system in the WTC area.

Table 8C-1 presents subway station usage for May 2001 for the five subway stations nearest the WTC site. Turnstile registrations, which are recordings of the number of people entering the system through each turnstile, are the most comprehensive source of data on subway ridership at

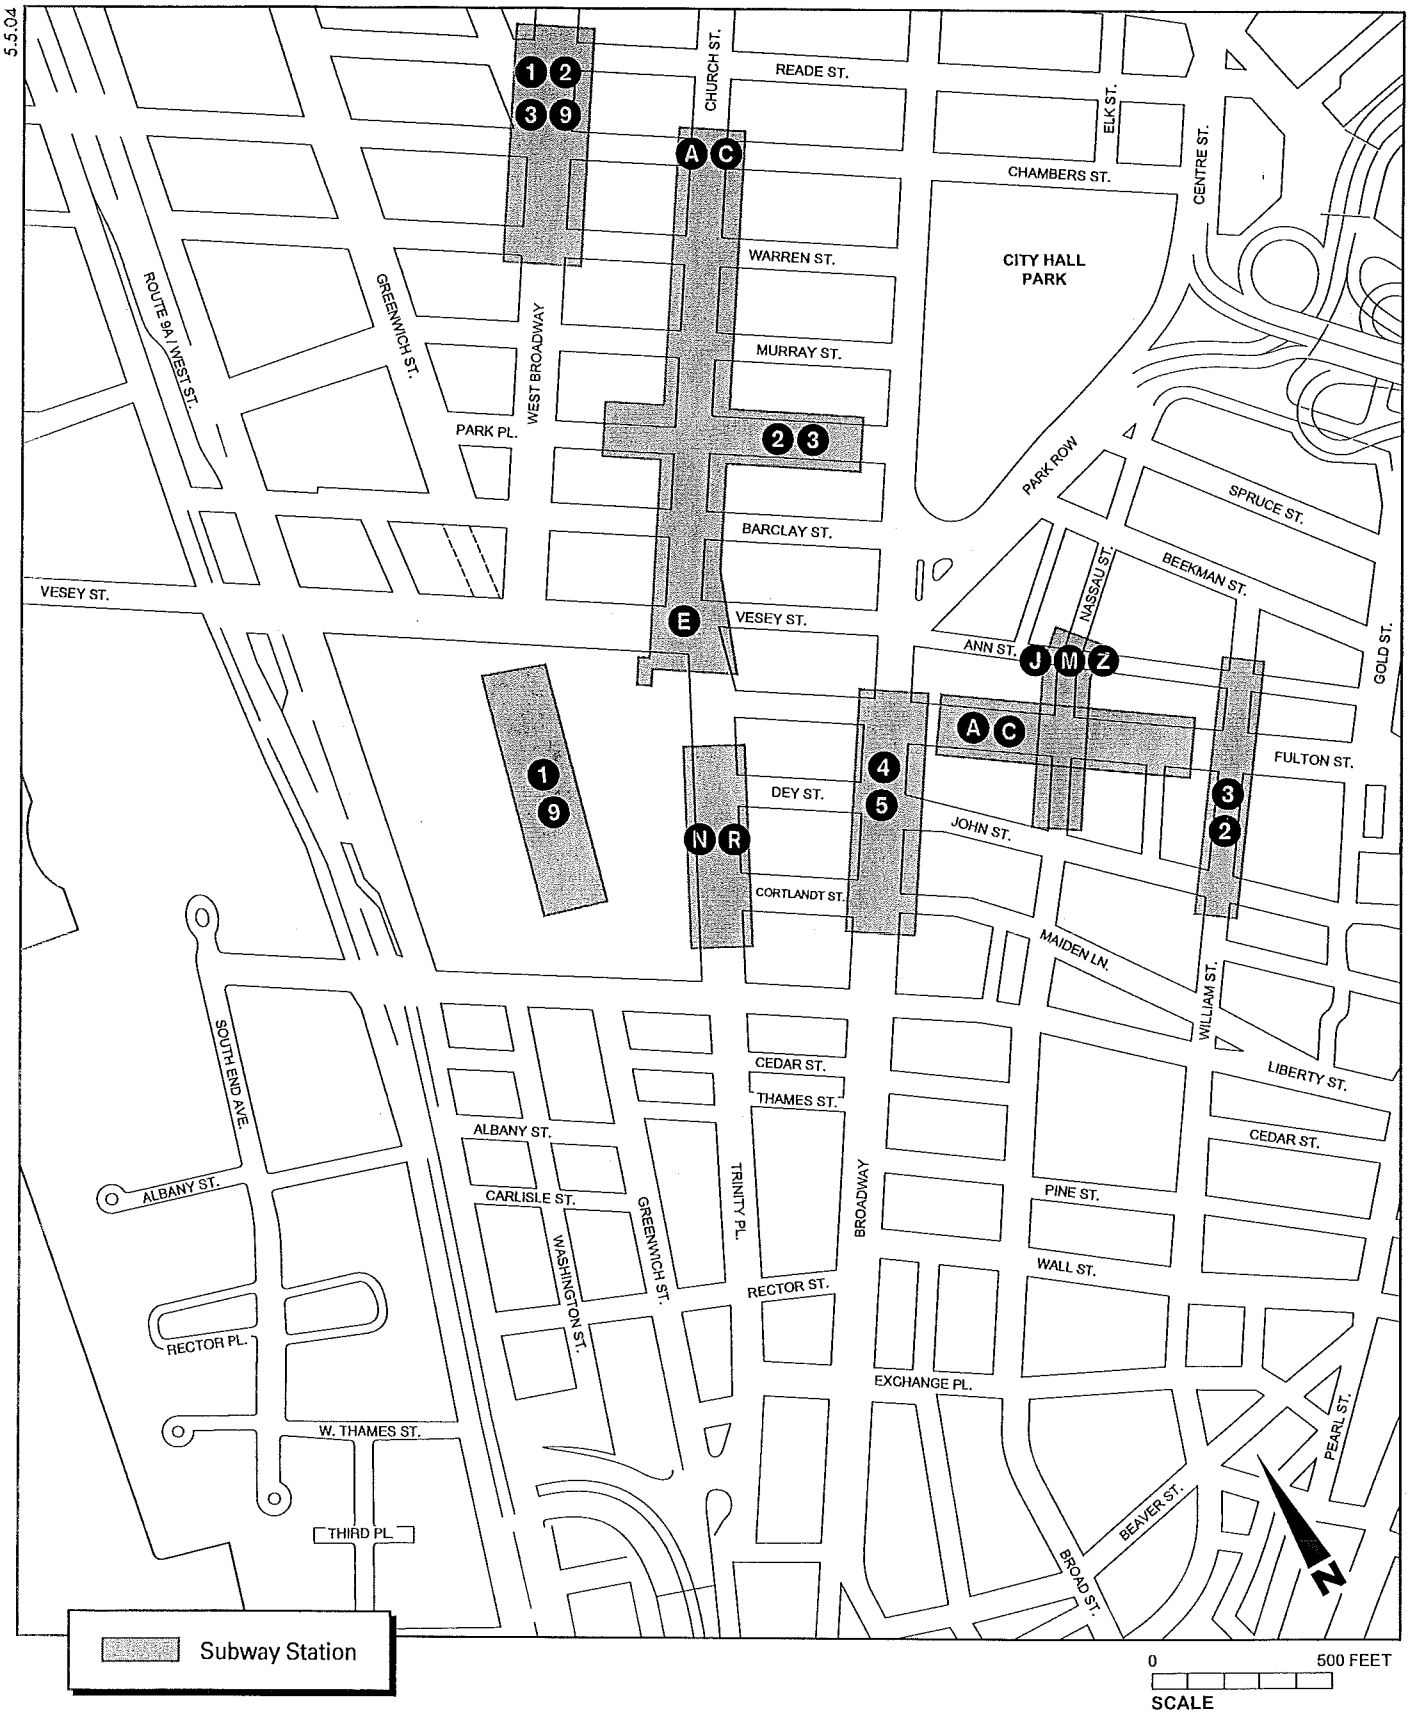

Figure 8C-1

Pre-September 11, 2001 Subway Station Locations

the station level. Although turnstile registrations provide a fair estimate of passenger boardings by station and time of day, comparable data is not available for passengers exiting each station. However, the patterns and magnitude of passenger flows can be assumed to be approximately the same during the morning peak period as during the evening peak given the high proportion of all trips that are related to commuting to work during the peaks. Thus, for example, according to Table 8C-1, 9,575 passengers entered the Cortlandt Street (1 and 9) Station between 4 PM and 7 PM, and approximately the same number of passengers would be expected to have exited the same station during the morning peak period.

Table 8C-1
Pre-September 11, 2001 (May 2001) Average Weekday Subway Turnstile Registration

Station	Routes	Time Period		
		6 AM – 9 AM	4 PM – 7 PM	24 Hour
Cortlandt Street	1, 9	1,569	9,575	19,446
Chambers Street	1, 2, 3, 9	1,219	5,880	17,432
Cortlandt Street	N, R	3,391	11,764	27,650
Fulton Street/Broadway-Nassau	A, C, J, M, Z, 2, 3, 4, 5	3,090	33,215	65,941
Chambers Street/ WTC/Park Place	A, C, E, 2, 3	3,949	28,742	62,713
Total		13,218	89,176	193,182

Source: New York City Transit

A subway line haul analysis was performed for the *WTC Memorial and Redevelopment Plan Generic Environmental Impact Statement (GEIS)*, using the *CEQR Technical Manual* guidelines for subway capacity, with ridership and subway data provided by NYCT. Volume to capacity (v/c) ratios were calculated for each subway line for the AM peak hour (8AM to 9AM). As shown in Table 8C-2, the southbound 5 train at Fulton Street operated above capacity with entering station v/c ratios of 1.36. The other subway lines that served the WTC area, including the 1 and 9 trains at Cortlandt Street, the N and R trains at Cortlandt Street, and the E train at WTC, operated well below capacity. The northbound 1 and 9 trains and the northbound 4 train had slightly higher leaving station v/c ratios compared with entering station v/c ratios, an indication that there was some reverse commuting from Lower Manhattan (i.e. passengers transferring from PATH and ferries).

LOCAL BUS SERVICE

The roles of local buses are to serve the immediate Lower Manhattan area and to connect it with various parts of Manhattan to the north and Downtown Brooklyn. Local bus routes are designed to collect and distribute passengers throughout the service area. All local bus routes operated during the weekdays and most provided weekend service. All public local bus routes were operated by NYCT and provided extensive service throughout Lower Manhattan. NYCT operated 12 local bus routes in Lower Manhattan including the M1, M1 Limited, M6, M9, M15 (South Ferry), M15 Limited (South Ferry), M15 (City Hall/Park Row), M15 Limited (City Hall/Park Row), M20, M22, M103, and B51.

Table 8C-2

Pre-September 11, 2001 (May 2001) Subway Line-Haul for WTC Area Stations

Station	Route	Direction	Peak Hour Capacity	Arrival Load		Leave Load

		Southbound	19,360	666	0.03	235	0.01

Source: *WTC Memorial and Redevelopment Plan Generic Environmental Impact Statement* (GEIS).

Since local buses operated with relatively short headways (less than 10 minutes) and made many stops, service was frequent throughout Lower Manhattan, particularly during weekday morning and afternoon peak periods. All local bus routes in the study area started/terminated in Lower Manhattan and connected with destinations in Midtown and Upper Manhattan with the exception of the B51, which operated between Lower Manhattan and Downtown Brooklyn via the Manhattan Bridge. The busiest local bus route in Lower Manhattan (and New York City) was the M15 (including limited-stop service), which typically served over 65,000 riders on an average weekday. The M15 was also the only bus route with two different terminal points in Lower Manhattan (South Ferry and Park Row/City Hall). The M15 and the M1 routes operated "limited stop" local service that skipped selected bus stops to provide faster service.

The closest local bus service to the WTC site was provided by the M1 from Harlem and M6 from Central Park South. These two bus routes traveled southbound along Broadway to South Ferry and northbound on Trinity Place/Church Street for their return trips uptown. Other nearby bus routes east of the WTC site included the M15 (Harlem), M103 (Harlem), and B51 (Downtown Brooklyn) routes, which all terminated at City Hall/Park Row (a 5-10 minute walk from the WTC site). West of the WTC, three local bus routes provided local service. The M22 traveled between Grand Street/FDR Drive on the Lower East Side via westbound Chambers Street to the World Financial Center at Vesey Street. On its eastbound trip, the M22 also passed along City Hall/Park Row. Terminating at Battery Park City were the M20 from Lincoln Center from the north and the M9 from Union Square, which approached from the south. Both bus

routes served the WTC site along Route 9A and South End Avenue. A map of each of the aforementioned local bus routes serving Lower Manhattan is provided in Figure 8C-2. Table 8C-3 presents the pre-September 11, 2001 data provided by NYCT on the average weekday bus ridership for the total length of these routes. This data was obtained from the Urban Planning and Transportation Study that was prepared in September 2002 by the Port Authority of New York and New Jersey (PANYNJ) and the Lower Manhattan Development Corporation (LMDC).

Table 8C-3
Pre-September 11, 2001 Average Weekday Local Bus Ridership

Route	Ridership
M1 & M1 Limited	19,080
M6	7,198
M9	5,015
M15 (all variations)	65,385
M20	5,150
M22	3,927
M103	15,402
B51	927
Total	122,084

Source: *Lower Manhattan and the World Trade Center Site: Urban Planning and Transportation Study* (PANYNJ and LMDC, September 2002)

EXPRESS BUS SERVICE

The role of express bus service in the study area is to serve commuters from communities generally outside of Manhattan, and to transport them to and from Lower Manhattan. A total of 36 express bus routes operated between Lower Manhattan and various parts of New York City (mostly the outer boroughs). These express bus routes operated on a limited schedule (usually during the morning and evening peak periods) and were designed to bring commuters from distant locations into Lower Manhattan in a quick and efficient manner. New York express bus routes utilized one of three travel corridors within Lower Manhattan—Broadway/Church Street, Route 9A, or Water Street.

NYCT operated the majority of New York City express bus routes to and from Lower Manhattan, including 20 routes from Staten Island and three routes each from Manhattan and Brooklyn. To many Staten Island commuters, these routes provided the only direct transit service to Manhattan other than the Staten Island Ferry. Staten Island express bus service was operated solely by NYCT and included the X3 and X4 buses, which terminated on Murray Street in Battery Park City; the X8, which terminated on Frankfort Street; the X11, X12A, X16, X17A and X19 buses, which terminated on Worth Street and Broadway; the X13, X15, X18 and X20 buses, which terminated on Water Street and Broad Street; and the X1, X6, X7, X9, X10, X12B, X14 and X17C buses, which stopped in Lower Manhattan but terminated elsewhere. NYCT also operated three express buses, X25, X90, and X92, to Lower Manhattan from Manhattan's East Side and three express routes from Brooklyn, the X27, X28 and X29.

There were ten other New York City express bus routes subsidized by the New York City Department of Transportation (NYCDOT) and operated by private bus companies. Command Bus Company operated five bus routes from Brooklyn (BM1, BM2, BM2S, BM3 and BM4). Queens Surface Corp. and Triborough Coach Lines each operated two bus routes from Queens

(QM1, QM1A, QM11 and QM24W). Liberty Lines Express operated one bus route from the Bronx (BxM18). A map of the express bus routes serving Lower Manhattan is provided in Figure 8C-3. Table 8C-4 presents the average weekday ridership for NYCT and NYCDOT subsidized express bus routes for pre-September 11, 2001.

Table 8C-4
Pre-September 11, 2001 Average Weekday Express Bus Ridership

Source: *Lower Manhattan and the World Trade Center Site: PANYNJ and LMDC Urban Planning and Transportation Study* (Beyer Blinder Belle, September 2002)

Although of lesser importance due to the volume of riders and frequency of operations, it should also be noted that NJ Transit operated two commuter bus routes (120 and 134), Westchester County Bee-Line operated one route (BXM4C), ten privately operated express bus routes served

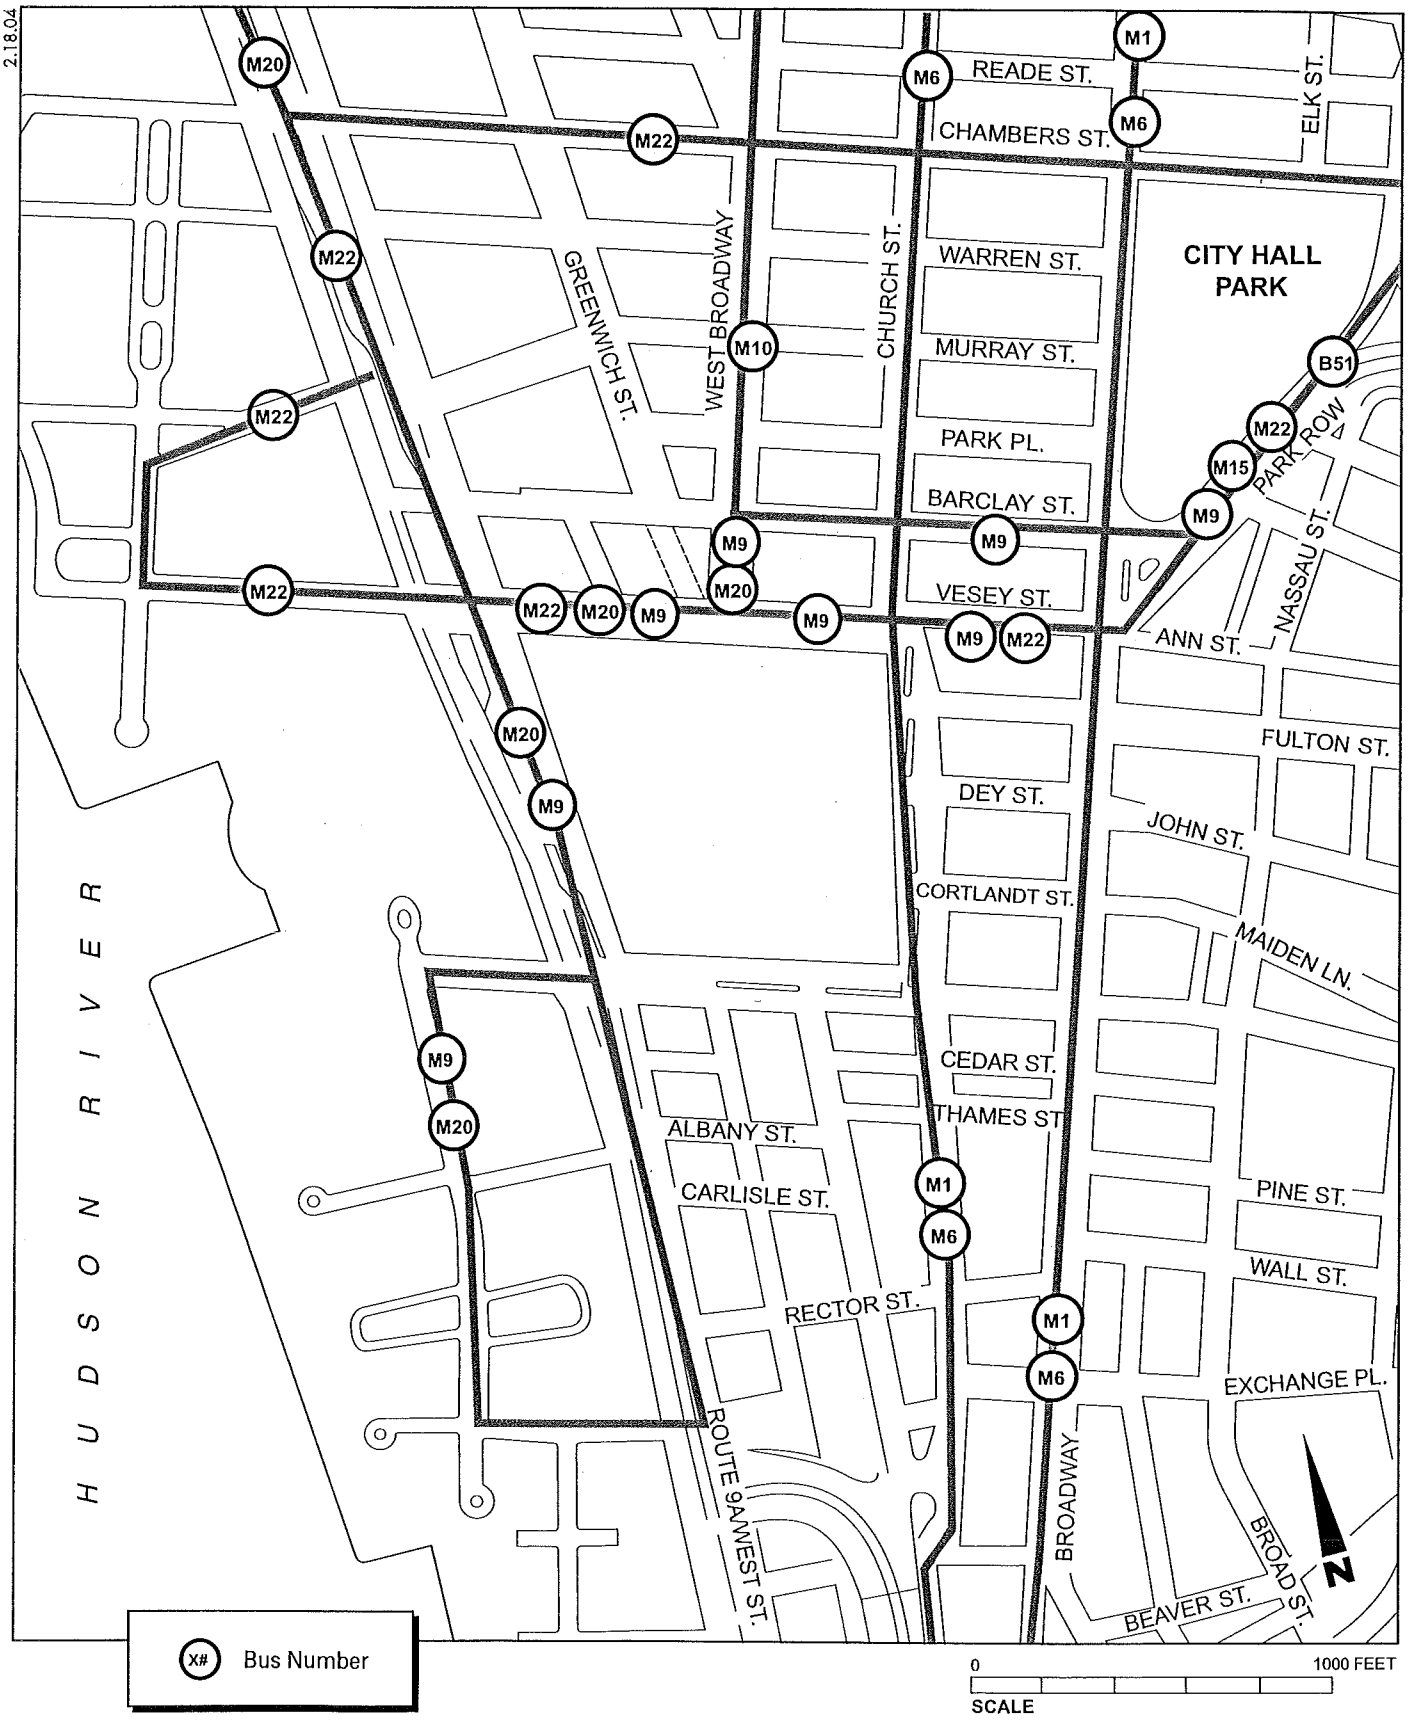

Figure 8C-2

Pre-September 11, 2001 Local Bus Routes

Pre-September 11, 2001
Express Bus Routes

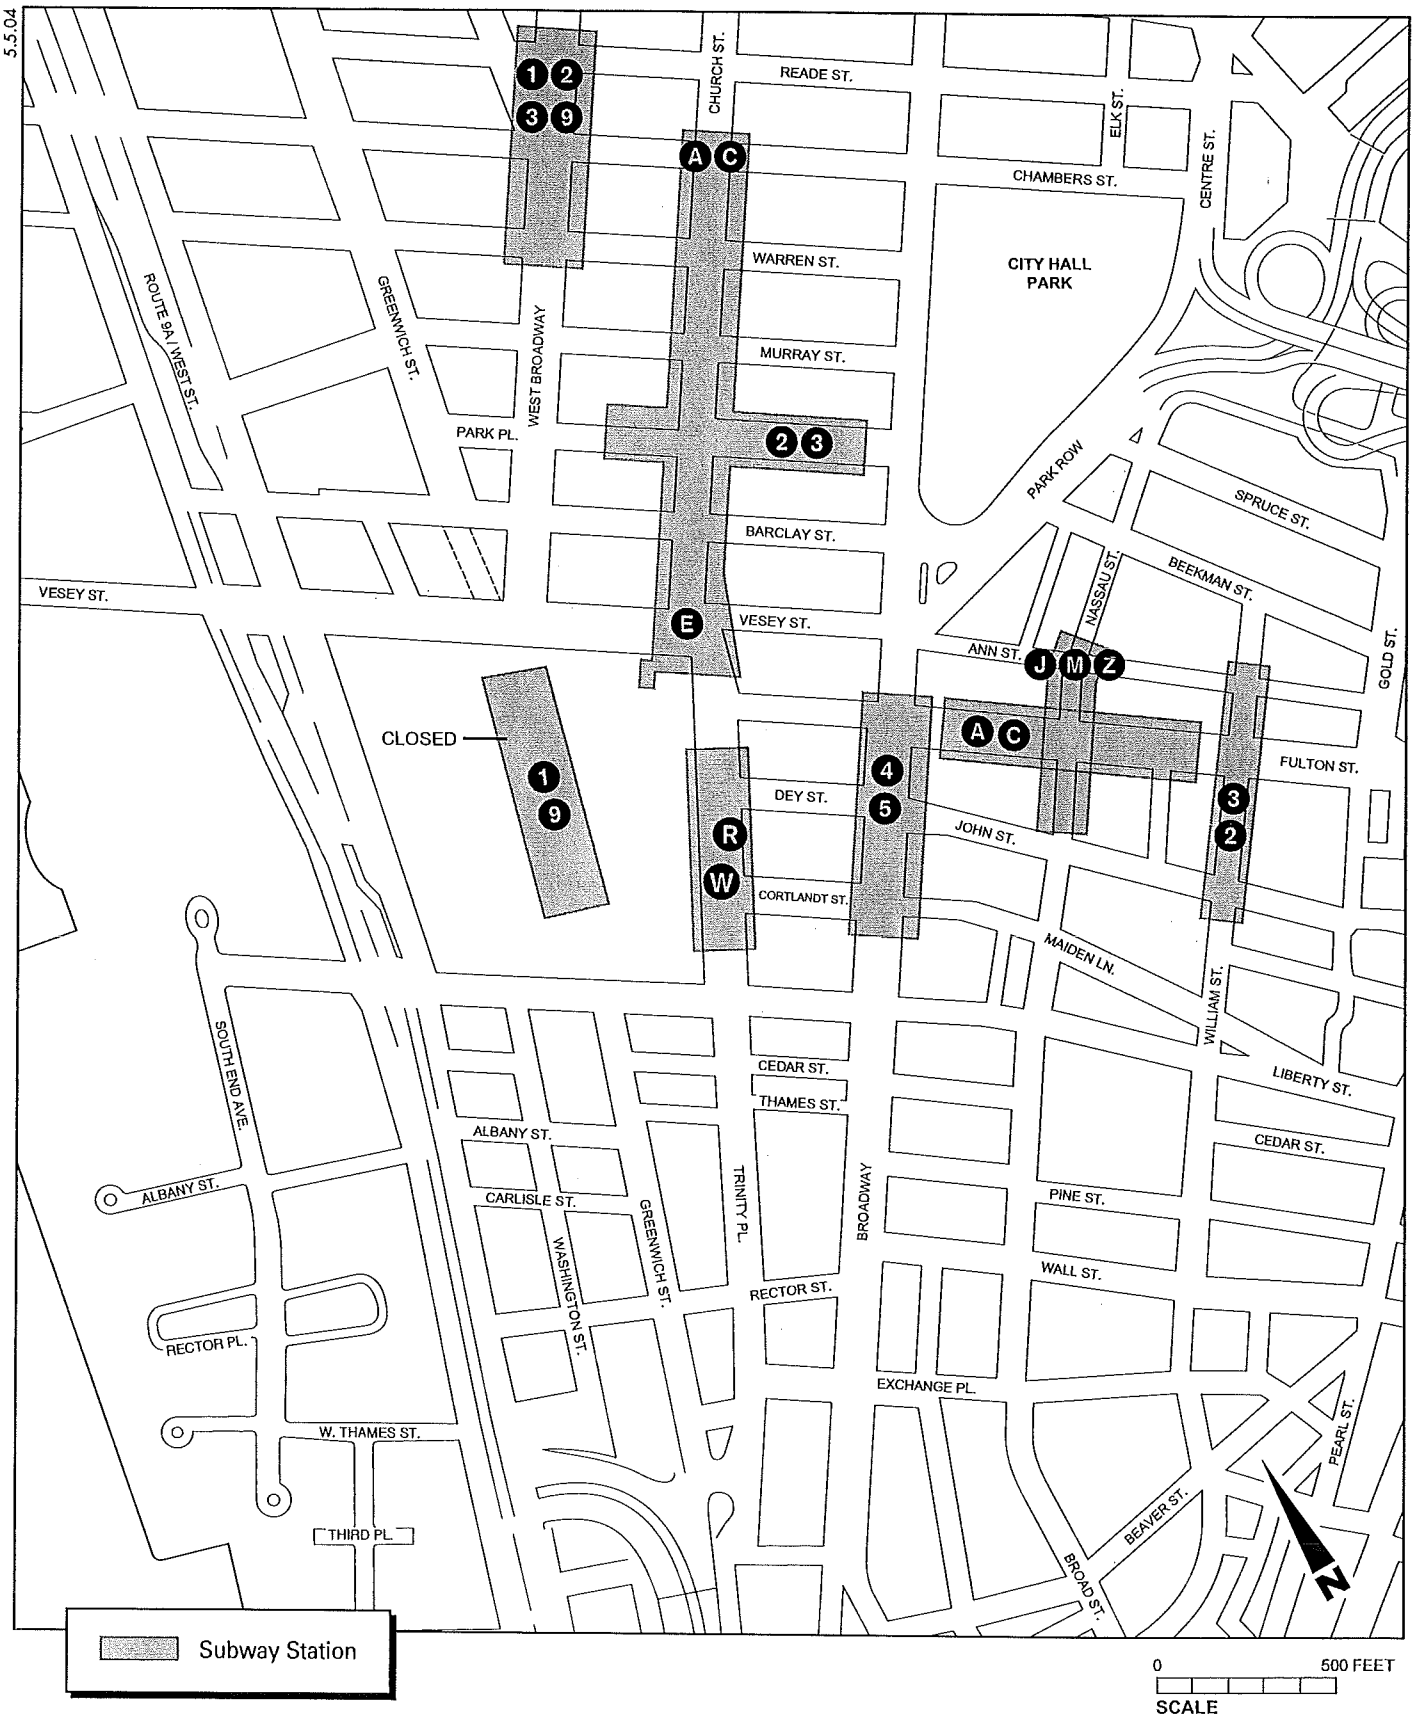

Figure 8C-4

Post-September 11, 2001 Subway Station Locations

suburban New Jersey communities, and two routes served Pennsylvania with Manhattan-bound morning peak period weekday service and outbound service during the evening peak period.

NEW JERSEY TRANSIT COMMUTER RAIL

Although NJ Transit commuter rail did not directly serve Lower Manhattan, many of its passengers used it in conjunction with PATH to do so. Prior to September 11, 2001, NJ Transit commuter rail passengers destined for Lower Manhattan would transfer to PATH service at either Newark or Hoboken depending on their particular line. Passengers on the Northeast Corridor, Raritan Valley, or North Jersey Coast Lines would transfer at Newark, while all other lines would transfer at Hoboken.

TRANS-HUDSON FERRIES

Prior to September 11, 2001, trans-Hudson ferry service was a small but growing part of the transportation network in Lower Manhattan consisting of almost 17,000 average weekday passengers. Table 8C-5 provides a listing of the various trans-Hudson ferry routes that served Lower Manhattan prior to the events of September 11, 2001. Table 8C-5 also indicates the average weekday ridership for each of these ferry routes.

Table 8C-5
Pre-September 11, 2001 Trans-Hudson Ferry Routes to Lower Manhattan

Manhattan Landing	New Jersey Landing	Operator	Average Weekday Ridership
World Financial Center	Colgate (Jersey City, NJ)	NY Waterway	1,572
	Harborside (Jersey City, NJ)		1,478
	Hoboken (NJ Transit Terminal)		8,970
	Liberty Harbor Marina		258
North Cove Marina	Liberty Landing Marina	Liberty Park Water Taxi	545
Pier 11	Atlantic Highlands, NJ	Seastreak	500
	Highlands, NJ	Seastreak	777
	Highlands, NJ	New York Fast Ferry	791
	Port Imperial (Weehawken, NJ)	NY Waterway	1,194
	Port Liberte, NJ	NY Waterway	835
Total Average Weekday Ridership			16,920

CHANGES IN THE AFFECTED ENVIRONMENT SINCE SEPTEMBER 11, 2001

This section presents an overview of the various changes that were imposed on the WTC-area transit facilities and services due to the September 11, 2001 terrorist attacks. With the exception of the trans-Hudson ferries, the conditions described below do not reflect those after the temporary WTC PATH station was opened in November 2003. Following its opening, travel patterns to Lower Manhattan have begun to return to pre-September 11, 2001 conditions.

NYCT SUBWAY SERVICE

The NYCT subway system changed substantially as a result of September 11, 2001. Due to the destruction of the WTC concourse, which had been the principal point of access to the local Eighth Avenue (E) Subway Line WTC Station and the Broadway (N and R) Line's Cortlandt Street Station, these station facilities were immediately closed. Both of these subway stations were reopened, however, during the first half of 2002.

In addition, a portion of the Seventh Avenue Line (1 and 9) tunnel that traversed a portion of the WTC site was destroyed, severing the line and eliminating all service south of Chambers Street. Prior to the reconstruction and reopening of the damaged tunnel in September 2002, service along the entire Broadway Line was radically affected. Because of the need to continue to operate local service north of Chambers Street and the physical inability to turn back local trains at or south of Chambers Street, service was reconfigured to operate Seventh Avenue local trains through to Brooklyn. The 1 train operated as an all-stop local from the Bronx to New Lots Avenue, Brooklyn. The 9 train, which had previously provided rush-hour skip-stop service with the 1 train north of 137th Street, was discontinued. The 2 train retained its route, but operated as a local in Manhattan. The 3 train operated express between East 148th Street in Harlem to 14th Street. The resulting service provided considerably less express service in Manhattan and no connecting Manhattan express service from Brooklyn. Subway service at the southernmost stations in Manhattan on other subway lines, including the Eighth Avenue Express and Broadway Local lines, were increased to compensate in part for the loss of 1 and 9 service. Figure 8C-4 shows these NYCT subway system changes following September 11, 2001.

Since the reopening of the damaged 1 and 9 subway tunnel in September 2002, subway service along this Seventh Avenue Line has returned to pre-September 11, 2001 levels.

Table 8C-6 provides an overview of the average weekday subway ridership, measured in turnstile registrations, for May 2002. Subway ridership decreased substantially at the five stations that served the WTC site.

Table 8C-6
Post-September 11, 2001 (May 2002) Average Weekday Subway Turnstile Registration

Station	Time Period			Change (May 2001 to May 2002) 24-Hour Total	
	6-9 AM	4-7 PM	24 Hours	Ridership	Percent
Cortlandt Street (1/9)	0	0	0	-19,466	-100.0%
Chambers Street (1/2)	955	4,339	14,001	-3,431	-19.7%
Cortlandt Street (N/R)	0	0	0	-27,650	-100.0%
Fulton St./B'way-Nassau St. (1, 2, 4, 5, A, C, J, M, Z)	2,277	30,163	62,616	-3,325	-5.0%

Total	4,612	48,704	110,322		
Ridership Change (May 2001 to May 2002)	-8,606	-40,472	-82,860		
Percent Change (May 2001 to May 2002)	-65.1%	-45.4%	-42.9%		

Source: New York City Transit

Table 8C-7 summarizes the post-September 11, 2001 subway line haul results for the six subway stations in the vicinity of the WTC site for 2003. Due to the loss of employment in and reduction of commuter trips to Lower Manhattan, subway ridership and passenger distribution to the area's subway stations have altered. For the most part, line-haul levels at affected stations were lower than pre-September 11, 2001.

Table 8C-7
Post-September 11, 2001 (May 2002) Subway Line-Haul for WTC Area Stations

Station	Route	Direction	Total Peak Hour Capacity	Trains Entering Station		Trains Leaving Station	
				Volume	V/C	Volume	V/C

UPTOWN PATH LINES

Following the destruction of the WTC PATH Terminal on September 11, 2001, many commuters diverted to PATH's Midtown Manhattan routes. Once in Manhattan, these passengers connected to NYCT subways to reach destinations in Lower Manhattan. As a result, ridership at PATH's Christopher Street Station doubled from approximately 4,000 to 8,000 daily riders.

As a direct result of the dramatic increase in passengers exiting the Christopher Street PATH station in the morning, which has only one entry/exit location and narrow platforms, PANYNJ barred passengers from entering this station on weekdays from 7:00 to 9:45 AM. In addition, trains operating from Journal Square and Hoboken to 33rd Street did not stop at Christopher Street on weekdays from 4:30 to 7:00 PM.

LOCAL BUS SERVICE

Following September 11, 2001, NYCT's 12 local bus routes, which included the M1, M1 Limited, M6, M9, M15 (South Ferry), M15 Limited (South Ferry), M15 (City Hall/Park Row), M15 Limited (City Hall/Park Row), M20, M22, M103 and B51, continued to operate, albeit with some modifications to route and stop locations due to WTC-related street closings. Figure 8C-5 provides a map of these local bus routes following September 11, 2001.

The collective total ridership along the total length of these routes did not change substantially following September 11, 2001. Specific ridership data for the Lower Manhattan portion of these routes are not available, however. Table 8C-8 presents a comparison of pre- and post-September 11, 2001 average weekday bus ridership for the total length of these local routes.

Table 8C-8
Pre- and Post-September 11, 2001 Average Weekday Local Bus Ridership

Route	Pre-September 11, 2001	Post-September 11, 2001	Percent Change
M1 & M1 Limited	19,080	18,920	-0.8%
M6	7,198	7,089	-1.5%
M9	5,015	4,114	-18.0%
M15 (all variations)	65,385	65,422	0.1%
M20	5,150	6,172	19.8%
M22	3,927	3,679	-6.3%
M103	15,402	15,733	2.2%
B51	927	898	-3.1%
Total	122,084	122,027	-0.1%

EXPRESS BUS SERVICE

Express bus service continues to operate much as it did prior to September 11, 2001. In addition to routing changes and bus stop relocations in Lower Manhattan due to street closings, the only other changes to NYCT express bus service involved the elimination of the X14 route from Staten Island and the implementation of a new route (X26) between Penn Station-New York and Battery Park City. Figure 8C-6 provides a map of the NYCT and NYCDOT-subsidized express bus routes following September 11, 2001.

Table 8C-9 presents a comparison of pre- and post-September 11, 2001 average weekday ridership for NYCT and NYCDOT-subsidized express bus routes. As shown, ridership fell on the majority of these routes. Overall, express bus ridership decreased by about 2 percent.

Express bus ridership to Lower Manhattan decreased about 3 percent in total on the express bus services provided by NJ Transit (120 and 134), Westchester County Bee-Line (BXM4C), and the privately operated express bus routes serving suburban New Jersey (11 routes) and Pennsylvania (two routes), despite the addition of one new route provided by Academy Bus between Hoboken and Lower Manhattan.

NJ TRANSIT COMMUTER RAIL

Following the events of September 11, NJ Transit commuter rail services to New York City increased by approximately 30 percent, requiring additional trains on its routes serving New York's Penn Station. Although this additional capacity could accommodate the demand generated by the absence of PATH service to Lower Manhattan, it precluded certain service enhancements planned for the NJ Transit system.

For example, NJ Transit completed construction of the Secaucus Transfer, which provides a link between the Northeast Corridor line serving Penn Station and the Main and Bergen County lines that serve Hoboken. Prior to its opening, passengers on several NJ Transit commuter rail lines would travel to Hoboken and then connect to PATH trains or ferries to access Midtown Manhattan. With the Secaucus Transfer, these passengers can now connect to Penn Station-bound commuter trains, resulting in a shorter commute time. Although the project was completed in summer of 2003, its full opening was delayed until the opening of the temporary WTC PATH station because NJ Transit could not support the increased ridership associated both with diverted PATH passengers and the Secaucus Transfer.

TRANS-HUDSON FERRIES

Following the events of September 11, 2001, demand for ferry service between New Jersey and the WTC area increased by about 164 percent to almost 45,000 average weekday riders, using June 2002 ridership totals. Ferry operators rushed to respond to this demand by implementing increased peak hour service and new routes. To provide for these new services, ferry operators placed orders for over 20 new vessels, and chartered numerous fishing, whale watching, and sightseeing boats to augment capacity in the interim.

Table 8C-10 provides a list of the post-September 11, 2001, trans-Hudson ferry routes serving Lower Manhattan. In addition, Table 8C-10 indicates the average weekday ridership for each of these ferry routes and the percent change for each route from pre-September 11, 2001 levels.

Immediately following September 11, 2001, the World Financial Center ferry terminal was closed to the general public, and the Colgate, Harborside, Hoboken, and Liberty Harbor Marina services using this facility were rerouted to Pier 11 on the East River. The World Financial Center ferry terminal continued to play a key role by accommodating special charter ferries that provided the only access to the New York Mercantile Exchange in the weeks after it reopened on September 17th. This role expanded throughout the fall as other firms located at the World Financial Center contracted similar charter services for their employees.

With most ferry services between New Jersey and Lower Manhattan consolidated at Pier 11, the capacity of this terminal was soon proved inadequate for the high level of demand. Between September 11 and September 17, 2001, two additional barges were installed bringing the total number of slips at this facility to ten, but severe crowding continued.

In response, PANYNJ developed a new ferry terminal adjacent to Pier A on the west side of Battery Park. This facility consisted of a barge with a covered passenger waiting area and six slips. On November 5, 2001, all NY Waterway ferries from Hoboken and Harborside were diverted from Pier 11 to Pier A, as were the ferries serving the Liberty Landing Marina. This shortened the length of these routes, thereby reducing travel times and allowing an increase in service frequency. Limited service to the World Financial Center terminal from Hoboken South and Colgate was also restored at this time.

Table 8C-10
Comparison of Pre- and Post-September 11, 2001 (June 2002) Trans-Hudson Ferry Ridership to Lower Manhattan

Manhattan Landing	New Jersey Landing	Operator	Net Change	
			Riders	Percent
World Financial Center	Colgate (Jersey City, NJ)	NY Waterway	4,626	194%
	Harborside (Jersey City, NJ)		0	-100%

	World Financial Center Shuttle	NY Waterway	86	N/A
Total Average Weekday Ridership			44,632	164%

Notes: Pier A opened on November 5, 2001.
Source: *Lower Manhattan and the World Trade Center Site: PANYNJ and LMDC Urban Planning and Transportation Study* (Beyer Blinder Belle, September 2002)

Prior to the opening of the temporary WTC PATH station, trans-Hudson ferry services were distributed among three Lower Manhattan facilities: World Financial Center, Pier A, and Pier 11. Ferry service from the Jersey City communities of Colgate and Harborside were accommodated at Pier 11 on the east side of Manhattan. Colgate ferries also called at the World Financial Center with Harborside ferries calling at Pier A. Hoboken South ferries provided service to all three Lower Manhattan landings. The Newport service operated to Pier A exclusively, while ferries from the Liberty Landing Marina in Jersey City served Pier A and the North Cove Marina at Battery Park City. The Liberty Harbor Marina ferry served Pier 11. The ferries from Port Liberte and Port Imperial (Weehawken) continued to call at Pier 11. Direct service was also provided between Weehawken and the World Financial Center.

Of the ferry landings in Manhattan, Pier 11 on the East River saw the greatest increase in demand since September 11, 2001. Using June 2002 ridership data, passengers using this facility averaged more than 17,600 on a typical weekday, a nearly 300 percent increase over pre-September 11, 2001 levels. Much of this increase is attributable to the introduction to this facility of routes serving landings in Jersey City, Hoboken, and South Amboy, New Jersey. The ferry service to and from NJ Transit's Hoboken Terminal (Hoboken South) was the most heavily patronized of the services calling at Pier 11 with an average weekday ridership of almost 6,400 passengers, followed by the Colgate, Jersey City, route with 3,500. Both of these routes were implemented post-September 11, 2001. The ferry service at Port Imperial in Weehawken, previously the most heavily patronized Pier 11 service, experienced a 46 percent increase in ridership to about 1,750 passengers. Ridership on Seastreak's Highlands and Atlantic Highlands, New Jersey, runs also showed marked increases of 78 percent and 59 percent, respectively. Contrary to this trend has been the Port Liberte service, which experienced a 21 percent decrease in ridership from pre-September 11, 2001 levels.

When the temporary WTC PATH station reopened in November 2003, trans-Hudson ferry ridership decreased substantially. In response to this drop in demand, the Pier A ferry landing in Lower Manhattan was decommissioned and several ferry routes were discontinued. Figure 8C-7 provides a map of current trans-Hudson ferry service routes.

As shown in Table 8C-11, ridership on an average weekday during this period was 27,197 passengers. This was approximately a 61 percent decrease from ridership levels experienced in June 2002, prior to the opening of the temporary WTC PATH station. However, when compared to pre-September 11, 2001 ridership levels of 16,920 average weekday passengers, this was an increase of almost 61 percent despite the fact that lower ridership levels are typical of ferries during the winter months when the most recent data was obtained.

Table 8C-11

Trans-Hudson Ferry Ridership with Temporary PATH Service (January 2004)

Manhattan Landing	New Jersey Landing	Average Weekday Ridership
World Financial Center	Colgate (Jersey City, NJ)	2,520
	Hoboken (NJ Transit Terminal)	4,759
	Port Imperial (Weehawken, NJ)	363
North Cove Marina	Liberty Landing Marina	646
Pier 11	Atlantic Highlands, NJ	872
	Colgate (Jersey City, NJ)	1,609
	Highlands, NJ	1,184
	Belford, NJ	2,021
	Hoboken (NJ Transit Terminal)	7,191
	Newport, NJ	826
	Liberty Harbor Marina	1,605
	Port Imperial (Weehawken, NJ)	1,547
	Port Liberte, NJ	753
	South Amboy, NJ	660
	Harborside (Jersey City, NJ)	641
Total Average Weekday Ridership		27,197

Post-September 11, 2001 (June 2003)
Trans-Hudson Ferry Routes

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

CONSTRUCTION PERIOD (2006)

FUTURE COMMON TO ALL ALTERNATIVES

During the construction period of the Preferred Alternative, other transit projects would be under development in the study area, including the Fulton Street Transit Center, South Ferry Terminal, and Cortlandt Street Station. It is expected that these projects would open prior to or concurrent with the Permanent WTC PATH Terminal such that all of these facilities would be operational in 2009. However, a new World Financial Center Ferry Terminal, which is independent of the Preferred Alternative, is expected to be fully operational in 2005.

PANYNJ is constructing a new ferry terminal at the World Financial Center. Located on the Hudson River at the foot of Vesey Street, the new terminal will replace the existing, temporary facility adjacent to the Winter Garden. The new terminal has the capacity to berth a maximum of five vessels (four end loading and on side loading vessels). The terminal public space is designed to handle two full boat loads of 400 arriving passengers (800 total) and half a boat load of departing passengers (200 total) at any given time. The floating terminal will have a fabric roof, glass walls, restrooms, ticket booth and a concession area. Construction is expected to be completed by the end of 2005.

NO ACTION ALTERNATIVE

The temporary WTC PATH station was designed to accommodate anticipated passenger volumes through the construction period, years 2005 to 2008. If the Preferred Alternative is not undertaken, the temporary WTC PATH station would continue to provide access to Lower Manhattan for PATH passengers during these years. Therefore, the No Action Alternative would not impact transit passengers, which include users of local and express buses, commuter rail, commuter vans, NYCT subways, and ferries, during the construction period.

PREFERRED ALTERNATIVE

The construction of the Preferred Alternative is expected to induce a modest amount of construction-related roadway traffic to the area above the volume of construction vehicles associated with the rebuilding of the WTC itself and other projects in the area. This construction activity may lead to temporary closing, re-alignment, or narrowing of sidewalks and pedestrian passageways used to access subway station entrances/exits in the immediate area, specifically to the R and W line's Cortlandt Street Station and the E line's WTC Station. At no time, however, would any area subway station be completely closed due to construction activities. A Maintenance and Protection of Traffic (MPT) plan, which would include pedestrian traffic, would be in place during the construction period. Otherwise, no construction-related impacts are anticipated for NYCT subway riders or operations.

Construction-related activity may also require the temporary relocation or closing of bus stops and/or layover locations in the vicinity of the WTC site as well as the closing, re-alignment or narrowing of sidewalks used to access some bus stops. Construction-related traffic may thus modestly impact bus operations in the immediate area.

Construction activity associated with the Preferred Alternative is not anticipated to impact ferry riders or operations.

OPENING YEAR (2009)

FUTURE COMMON TO ALL ALTERNATIVES

In addition to their planning for a Permanent WTC PATH Terminal, PANYNJ is planning to implement improvements elsewhere on the PATH system as described in Chapter 8, Section A, "PATH". In addition, other transit agencies are planning projects that will collectively improve access to, from, and within Lower Manhattan by the 2009 opening year. These current proposals are described below.

Fulton Street Transit Center

The Fulton Street Transit Center will rehabilitate, reconfigure, and enhance the multilevel complex of subway stations in the area of Fulton Street, Nassau Street, and Broadway, and will provide new connections to stations on Church Street. The project will improve platforms, mezzanines, and connecting corridors, and will provide a new central concourse with an above-grade presence. The facility has a below-grade concourse connection to NYCT's R and W station at Cortlandt Street and the Preferred Alternative's lower concourse. The Fulton Street Transit Center is projected for completion by 2009.

Cortlandt Street Station Reconstruction

MTA will reconstruct the Cortlandt Street Station on the 1 and 9 line, which has been closed since the terrorist attacks. It is expected that the Cortlandt Street Station will reopen in 2009.

South Ferry Terminal

The MTA will reconstruct the existing South Ferry Subway Station into a new terminal that will eliminate the physical and operational deficiencies of the existing station, improve reliability of 1/9 service along either line, and improve intermodal connectivity with other transit services in its vicinity. South Ferry is the southern terminus of the NYCT 1 and 9 subway lines, which serve the full length of the west side between South Ferry and 242nd Street in the Bronx. The South Ferry Terminal will consist of two levels: the lower level will contain two transit tracks serving a single-island platform, and the upper level will house the fare-control mezzanine and a connection to the Whitehall Street Station of the R and W subway lines. Construction on the project is anticipated to commence in 2005, with a completion in late 2007.

Hudson-Bergen Light Rail

In 2005, NJ Transit plans to open Minimum Operating Segment (MOS) 2 of the Hudson-Bergen Light Rail system. This segment will extend service from Hoboken Terminal to the Tonnelle Avenue Park-and-Ride in North Bergen, New Jersey. NJ Transit and FTA are also preparing an Environmental Impact Statement for MOS3 of the HBLR, which would extend service south in Bayonne from 22nd Street to 8th Street and north from Tonnelle Avenue to a terminus in Tenafly. It is anticipated that the MOS3 will be completed before 2025.

The HBLR has transfers to the PATH system at Hoboken and Exchange Place. As the expansions are completed, it is anticipated that some commuters would use HBLR and PATH for their travel to Lower Manhattan. It is expected that these commuters would primarily divert from private automobiles or from NJ Transit commuter rail and buses. As noted in Chapter 8, Section A, "PATH," the PATH ridership projections include these potential diversions.

NO ACTION ALTERNATIVE

If the Preferred Alternative is not constructed, it is expected that the temporary WTC PATH station presently operating would continue service in the opening year. Although its current transit connections would be retained, it is not expected that the temporary station would be directly linked to the reconstructed Cortlandt Street Station (1 and 9 line) or the completed Fulton Street Transit Center.

PREFERRED ALTERNATIVE

No impacts to transit riders or operations (subway, bus, or ferry) are expected once the Preferred Alternative is fully operational in 2009. The Preferred Alternative is not expected to induce PATH ridership beyond levels that would have occurred had the terrorist attacks not happened. Therefore, this alternative would not generate additional unforeseen ridership on NYCT subways, local or express bus service, NJ Transit commuter rail, or trans-Hudson ferries from transferring PATH riders.

The Preferred Alternative would provide greater passenger capacity than the temporary WTC PATH station currently in service, comparable to the former WTC PATH Terminal. This additional PATH capacity would serve to alleviate crowding on complementary transit services such as trans-Hudson ferry and bus service and downtown-bound subway service from Penn Station-New York.

The Preferred Alternative would provide weather-protected and ADA-compliant pedestrian connections between the PATH rail system, the NYCT subway system, and to area buildings, and would provide more convenient access to trans-Hudson ferries.

DESIGN YEAR (2025)

FUTURE COMMON TO ALL ALTERNATIVES

Transportation and transit infrastructure, in particular, are a key component of the redevelopment plans for Lower Manhattan. Several projects are currently being studied or planned that would improve existing facilities and would provide for new routes to serve the area. In addition to the projects described above for the construction period and the opening year as well as PATH system improvements shown in Chapter 8, Section A, "PATH" and above, two new facilities would be completed by 2025.

Second Avenue Subway

The Metropolitan Transportation Authority (MTA) plans to construct a new subway line along Manhattan's east side from 125th Street to Hanover Square. In the vicinity of the Project Site, the Second Avenue Subway would follow Water Street with a station located at Fulton Street. FTA issued a Record of Decision for the Second Avenue Subway in 2004.

JFK Airport Access

LMDC, MTA, PANYNJ, and the New York City Economic Development Corporation undertook a transportation study to identify a feasible rail link that will 1) serve Long Island commuters by creating a direct connection between Lower Manhattan and the Long Island Rail Road's Jamaica station, and 2) serve JFK airport passengers by improving the connection between Lower Manhattan and JFK International Airport. The study identified two leading

options: Constructing a New Tunnel across the East River, and utilizing the existing MTA-NYCT's Montague Tunnel which currently serves the M and R subway services. The proposed Lower Manhattan terminal for this rail service would be connected to the Fulton Street Transit Center and the Permanent WTC PATH Terminal. The rail access to JFK will be undertaken as a separate action from this project and will undergo an independent environmental review.

NO ACTION ALTERNATIVE

By 2025 under the No Action Alternative, the temporary WTC PATH station would close and service between New Jersey and Lower Manhattan would be suspended. Thus, WTC-bound PATH passengers would be diverted to other modes of travel. Given this worst case scenario, 153,632 projected weekday WTC PATH Terminal users in design year 2025 would divert to other modes of public transportation to access Lower Manhattan, and 27,551 passengers would divert during the AM peak hour. The majority of these commuters would require a more expensive and time-consuming commute, potentially involving additional transfers, than if the Preferred Alternative were operational. Table 8C-12 provides projected weekday and AM peak hour diversions for each available mode of public transportation for the year 2025.

Although current trans-Hudson buses and commuter vans are operating at or near capacity during peak hours, added capacity may be obtained through the purchase and operation of additional vehicles, as was noted above for the opening year condition. The impact of these additional buses and vans to the roadway network are described further in Chapter 8, Section B.

The passenger capacity of ferries may also be increased through the operation of additional boats or larger boats. Port infrastructure would likely need to be expanded to accommodate the demand for ferry services.

During the AM peak hour, the NYCT subway system would be required to serve over 11,000 added passengers. As discussed earlier in this section, the subway system contains available line-haul capacity to accommodate passengers transferring from NJ Transit commuter rail, PABT-bound buses, and Midtown Manhattan PATH passengers.

Table 8C-12
2025 No Action Alternative: Diversions to Public Transportation without the Permanent WTC PATH Terminal

Mode	Diverted Weekday Passenger Trips	Diverted AM Peak Hour Passenger Trips
Bus to Lower Manhattan	33,961	6,090
Bus to PABT / NYCT Subway	8,086	1,450
Commuter Railroad / NYCT Subway	29,109	5,220
Commuter Van	1,617	290
Ferry	56,601	10,150
Uptown PATH / NYCT Subway	24,258	4,350
Total	153,632	27,551

Notes: The "Diverted Weekday Passenger Trips" are considered conservative estimates since they are derived using the projected number of trips anticipated for the Permanent WTC PATH Terminal. Without this investment in public transportation infrastructure, the number of trips to Lower Manhattan from west-of-Hudson locations would be somewhat less.

The No Action Alternative, on the other hand, would severely impact NJ Transit commuter rail services. During the AM peak hour, the system would be required to accommodate an additional 5,220 passengers, in addition to the ridership growth that NJ Transit would have already experienced. Severe crowding during the AM and PM peak periods would be commonplace. Train throughput would also be impacted as trains would require longer dwell times for passengers to board and alight.

In addition, although upgrades are planned for the Ninth Street PATH station, it will not have adequate capacity to support general system growth if the Preferred Alternative is not constructed.

PREFERRED ALTERNATIVE

No impacts to transit riders or operations (subway, bus, or ferry) are expected in the design year. The Preferred Alternative is not expected to induce PATH ridership beyond levels that would have occurred had the terrorist attacks not happened. Therefore, this alternative would not generate additional unforeseen ridership on NYCT subways, local or express bus service, NJ Transit commuter rail, or trans-Hudson ferries from transferring PATH riders.

The Preferred Alternative would provide greater passenger capacity than the temporary WTC PATH station currently in service, comparable to the former WTC PATH Terminal. This additional PATH capacity would serve to alleviate crowding on complementary transit services such as trans-Hudson ferry and bus service and downtown-bound subway service from Penn Station-New York.

The Preferred Alternative would provide weather-protected and ADA-compliant pedestrian connections between the PATH rail system, the NYCT subway system, and to area buildings, and would provide more convenient access to trans-Hudson ferries.

E. MITIGATION

The Preferred Alternative would not adversely impact the operation of other transit service to, from, and within Lower Manhattan. Since the Preferred Alternative would provide for enhanced PATH service and improved connectivity to other modes, any impacts to transit service would be beneficial. Thus, mitigation is not required. ✷

A. INTRODUCTION

This section describes on-street pedestrian conditions in the vicinity of the World Trade Center (WTC) site to identify whether the Permanent WTC PATH Terminal would adversely impact conditions in the area. The analyses that follow provide an overview of existing conditions, both before and after September 11, 2001, in order to establish a baseline from which future conditions are developed and can be compared. Pre-September 11, 2001 volumes were used to evaluate opening year (2009) and design year (2025) impacts. Conditions during the construction period (2006) are estimated based on current (post-September 11, 2001) activities.

The analyses focus on a pedestrian study area and representative intersections at which increases in congestion could occur as a result of the Terminal's construction or relocated on-street access points differing from the pre-September 11, 2001 WTC PATH Terminal. The Preferred Alternative includes improved pedestrian access for Lower Manhattan with connections to the World Financial Center and the Dey Street concourse, which would be constructed by the Metropolitan Transportation Authority (MTA) as part of the Fulton Street Transit Center.

The No Action and Preferred Alternatives, as evaluated in this Environmental Impact Statement (EIS), account for the numerous development projects planned for Lower Manhattan, including the World Trade Center Memorial and Redevelopment Plan, Washington Street Urban Renewal Area, Battery Park City, and other residential and commercial projects. With the exception of the World Trade Center Memorial and Redevelopment Plan, these projects were planned prior to September 11, 2001, and they were expected to generate new demand for PATH service. Projections of PATH ridership in the opening year (2009) and design year (2025) account for these planned developments, which would occur with or without the Preferred Alternative. Thus, the Preferred Alternative would not directly induce new PATH riders, exceeding levels that would have been experienced had the terrorist attacks not occurred. However, the analyses contained in this section indicate that some crosswalks are adversely impacted in the study area. These impacts are partially the result of increased activity from projects independent of the Preferred Alternative, such as the Memorial, a Performing Arts Center, and cultural facilities on the WTC site, as well as from repositioned access points to the Preferred Alternative. The impacts can be mitigated by widening crosswalks.

Per the analysis framework prepared for the Lower Manhattan recovery projects, the Preferred Alternative's potential impacts on pedestrian conditions is based on two baseline conditions. The first is a pre-September 11, 2001 baseline, which is used to evaluate project-generated impacts in the opening and design years. The pre-September 11, 2001 baseline is applied under the assumption that much of the activity in Lower Manhattan lost to the terrorist attacks would be restored by 2009. For the short-term construction-period analysis, the project's effects are compared to a baseline network that reflects 2003 conditions. This chapter describes potential impacts resulting only from the construction of the Preferred Alternative. The cumulative construction-period effects of PATH and the other Lower Manhattan recovery projects are

presented in Chapter 15, "Cumulative Effects." Given that the opening and design years analyses presented in this chapter assume a baseline condition that included the pre-September 11, 2001 WTC and PATH terminal, the build condition includes the other Lower Manhattan recovery projects. As such, the 2009 and 2025 analyses are essentially a cumulative impacts assessment for the recovery projects. However, in order to discern the relative effect of the new PATH Terminal, this chapter identifies the percentage of the impact attributed to changes in the on-street circulation of PATH riders. For those locations at which 50 percent or more of the new pedestrian volumes would be PATH riders, project-generated impacts are identified and mitigation measures are proposed.

B. METHODOLOGY

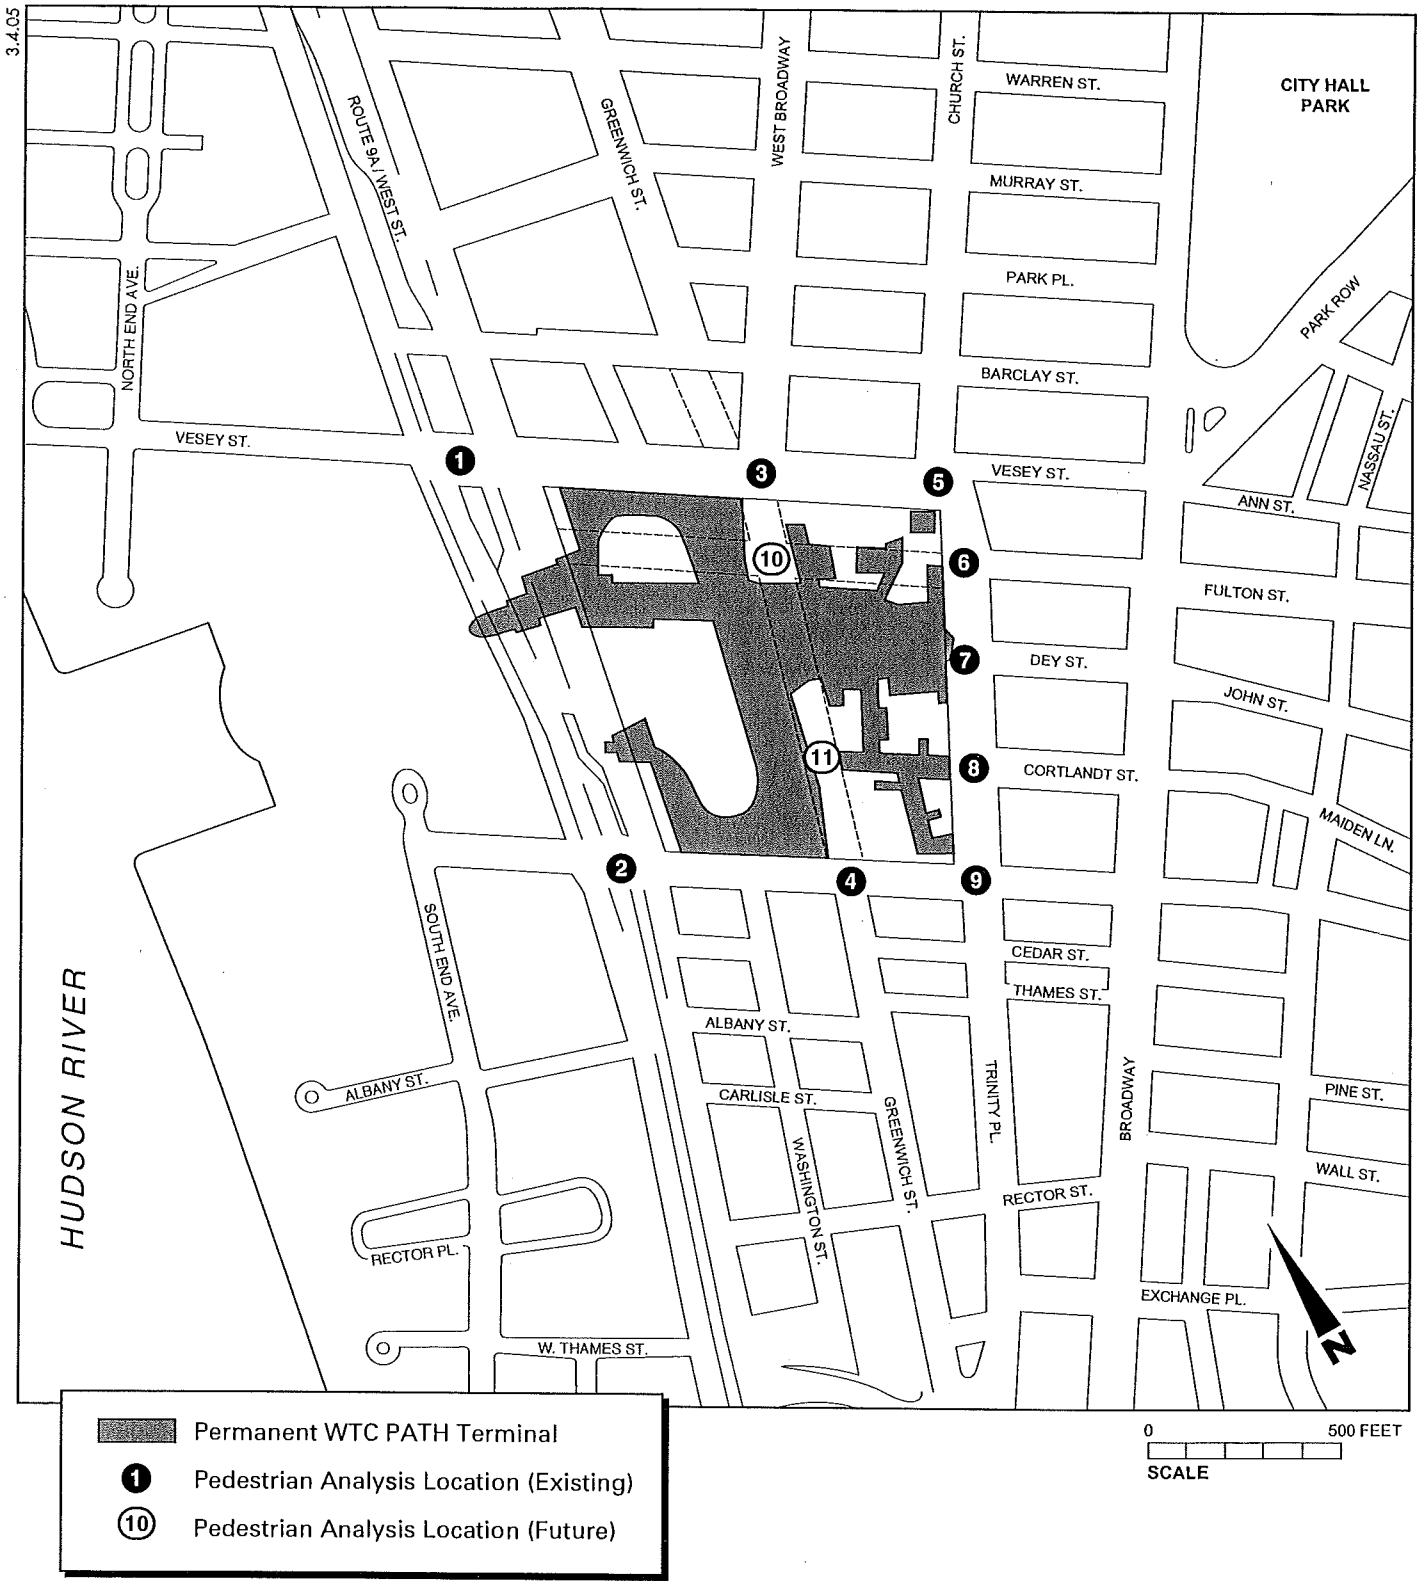
The pedestrian study area, illustrated in Figure 8D-1, includes the intersections that would most likely be used by future PATH patrons. These intersections include:

- Route 9A (West Street) at Vesey Street (north, south and east crosswalks);
- Route 9A (West Street) at Liberty Street (north, south and east crosswalks);
- West Broadway at Vesey Street (all crosswalks);
- Greenwich Street at Fulton Street (all crosswalks at new intersection);
- Greenwich Street at Cortlandt Street (new midblock crosswalk);
- Greenwich Street at Liberty Street (all crosswalks);
- Church Street at Vesey Street (all crosswalks);
- Church Street at Fulton Street (all crosswalks);
- Church Street at Dey Street (all crosswalks);
- Church Street at Cortlandt Street (all crosswalks); and
- Church Street at Liberty Street (all crosswalks and northwest corner reservoir).

To evaluate potential impacts during the construction period, the analyses compare pedestrian conditions with and without the Preferred Alternative in 2006. On-street pedestrian volumes in the construction period include pedestrian counts following September 11, 2001, projected temporary WTC PATH station riders, and growth in the period following September 11, 2001. Pedestrian network geometries were collected after September 11, 2001 and the latest Lower Manhattan construction staging plans were reviewed to model the analyses.

To evaluate potential impacts of the Preferred Alternative during the design year, projected future conditions are compared to on-street pedestrian conditions before September 11, 2001, the equivalent condition had the terrorist attacks not occurred. As described above, no new PATH ridership would be induced by the Preferred Alternative, but possible changes in pedestrian access patterns for new entry points may create differences in crosswalk flows.

Pedestrian volumes for pre-September 11, 2001 conditions were increased by 0.5 percent per year for comparison purposes. This rate is commonly applied to estimate background growth for development projects in Manhattan per methodologies specified in the *New York City Environmental Quality Review (CEQR) Technical Manual* (December 2001). Current volumes of on-street pedestrians are based on counts collected following September 11, 2001. Based on these survey data, three peak hours were selected for analysis: AM (8:15 AM to 9:15 AM), midday (12 PM to 1 PM) and PM (5 PM to 6 PM). Pedestrian volume networks were calculated as a joint effort between the Port Authority of New York and New Jersey (PANYNJ) for this EIS, and the Metropolitan Transportation Authority (MTA), New York State Department of



PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure 8D-1
Pedestrian Analysis Locations

Transportation (NYSDOT), and Lower Manhattan Development Corporation (LMDC) for their respective EISs to ensure consistency between these closely related projects.

The pedestrian level of service analyses were based on *2000 Highway Capacity Manual (HCM)* procedures, conducted for crosswalk and corner reservoir levels of service at key intersections that could be affected by the Preferred Alternative.

Crosswalks and street corner conditions are influenced by the effects of traffic signals. Street corners must be able to provide sufficient space for a mix of standing pedestrians (queued to cross a street) and circulating pedestrians (crossing the other street or moving around the corner). The *HCM* applies a measure of time and space availability based on the area of the corner, signal timings, and the space used by circulating pedestrians. The total "time-space" available for these activities is the net area of the corner (in square feet) multiplied by the signal cycle length and expressed as square feet-minutes. The analysis then determines the total circulation time for all pedestrian movements at the corner (expressed as pedestrian-minutes). The ratio of net circulation time-space divided by total pedestrian circulation time provides the level of service measurement of square feet per pedestrian.

Crosswalk level of service is also a function of time and space. Similar to corner analyses, crosswalk conditions are expressed as a measurement of the area available (the crosswalk width multiplied by the width of the street) and the signal timing, which is expressed as square feet-minutes. The average time required for a pedestrian to cross the street is calculated based on the width of the street and an assumed walking speed. As per guidance in the *CEQR Technical Manual*, a walking speed of 4 feet per second is commonly used for projects in New York City. The ratio of average crossing time to the time-space available in the crosswalk is the level of service measurement of available square feet per pedestrian. Additionally, in the first seconds of the "walk" cycle, the pedestrians queued to cross the street create a surge effect as they begin to cross. Therefore, the crosswalk level of service analysis incorporates a factor for this "surge" to estimate worst-case conditions. The level of service analysis also accounts for vehicular turning movements that pass through the crosswalk. Table 8D-1 summarizes level of service definitions for crosswalks and corner reservoirs.

For Manhattan, levels of service (LOS) A through D reflect acceptable conditions, while LOS E and F reflect congested conditions (*CEQR Technical Manual*, December 2001).

Off-street pedestrian flows were calculated by the PANYNJ Traffic Engineering Department to design the underground concourses of the Preferred Alternative. It is assumed that these concourses would be designed to process pedestrians at acceptable levels of service, and are therefore not analyzed in this EIS. Absent the Preferred Alternative, the WTC Memorial and Redevelopment would design a pedestrian network with sufficient capacity for pedestrians using the WTC site.

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

PRE-SEPTEMBER 11, 2001 BASELINE CONDITIONS

Prior to September 11, 2001, the pedestrian crossing network functioned at acceptable levels of service, with the exception of the Church Street intersections at Vesey, Fulton, Dey, Cortlandt, and Liberty Streets. These locations contained one or more crosswalks that operated at LOS E or

Table 8D-1
Pedestrian Level of Service Definitions

LOS	Circulation Area (Square Feet per Pedestrian)	Description
A	130+	Pedestrians move in desired paths without altering their movements in response to other pedestrians. Walking speeds are freely selected and conflicts between pedestrians are unlikely.
B	40-129	Sufficient area is provided to allow pedestrians to freely select walking speeds, to bypass other pedestrians and to avoid crossing conflicts with others. At this level, pedestrians begin to be aware of other pedestrians and to respond to their presence in the selection of their walking path.
C	24-39	Sufficient space is available to select normal walking speeds and to bypass other pedestrians in primarily unidirectional streams. Where reverse-direction or crossing movements exist, minor conflicts will occur and speeds and volume will be somewhat lower.
D	15-23	Freedom to select individual walking speed and to bypass other pedestrians is restricted. Where crossing reverse-flow movements exist, the probability of conflict is high and its avoidance requires frequent changes in speed and position. The level of service provides reasonably fluid flow; however, considerable friction and interaction between pedestrians is likely to occur.
E	6-14	Virtually all pedestrians would have their normal walking speed restricted, requiring frequent adjustment of gait. At the lower range of this level of service, forward movement is possible only by shuffling. Insufficient space is provided for passing of slower pedestrians. Cross- or reverse-flow movements are possible only with extreme difficulties. Design volumes approach the limit of walkway capacity, with resulting stoppages and interruptions in flow.
F	0-5	All walking speeds are severely restricted and forward progress is made only by shuffling. There is frequent, unavoidable contact with other pedestrians. Cross- and reverse-flow movements are virtually impossible. Flow is sporadic and unstable. Space is more characteristic of queued pedestrians than of moving pedestrians.

shopping traffic between the WTC site and points east of Church Street contributed to these conditions. Other crosswalks along Vesey and Liberty Streets operated with acceptable levels of service.

CHANGES IN THE AFFECTED ENVIRONMENT SINCE SEPTEMBER 11, 2001

Following September 11, 2001, the pedestrian network functioned at acceptable levels of service due to the substantially reduced pedestrian activity due to the absence of the WTC and the pre-September 11, 2001 WTC PATH Terminal, with the exception of the Church Street intersections at Vesey and Fulton Streets. These locations contained one or more crosswalks that operated at LOS E. The events of September 11, 2001, which destroyed the WTC PATH facility, resulted in a major shift in transit mode from New Jersey to Lower Manhattan. This demand was temporarily filled between September 12, 2001 and November 22, 2003 by increased ferry ridership to Lower Manhattan, increased PATH ridership to 33rd Street, Christopher Street, and 9th Street Stations with transfers to subways, and increased NJ Transit ridership with transfers to subways. Table 8D-3 summarizes the LOS analysis for conditions since September 11, 2001.

The west crosswalk at the intersection of Church and Vesey Streets experienced LOS E in the PM peak hour, and the east crosswalk at the intersection of Church and Fulton Streets experienced LOS E in the PM peak hour. Other crosswalks along Church, Vesey, and Liberty Streets operated at acceptable levels of service. Tourist, shopper, and business interaction between the temporary WTC site viewing area on Church Street and primary office and subway destinations to the east of Church Street contributed to these conditions.

The temporary WTC PATH station restored service to Lower Manhattan on November 23, 2003. Because pedestrian surveys for the post-September 11, 2001 conditions were conducted prior to the opening of the temporary WTC PATH station, trips directly associated with the facility are not reflected in the analysis results shown in Table 8D-3. However, future conditions in the 2006 construction period have been adjusted to account for trips to and from the temporary station.

The Route 9A pedestrian overpass at Liberty Street (formerly known as South Bridge) was destroyed on September 11, 2001 and reconstructed in approximately the same location. The Liberty Street overpass was reconstructed prior to pedestrian counts and observations conducted in 2003. The former North Bridge spanning Route 9A, which was located south of 3 World Financial Center at the Winter Garden, was also destroyed on September 11, 2001. However, the replacement pedestrian bridge was reconstructed north of 3 World Financial Center and south of Vesey Street in November 2003, after pedestrian counts and observations were conducted. Pedestrian conditions crossing Route 9A in the period following September 11, 2001 were analyzed under November 2003 conditions, which included pedestrian overpasses at Liberty and Vesey Streets, but did not include temporary WTC PATH station trips. According to observations, pedestrian levels of service at the overpasses were acceptable in the post-September 11, 2001 conditions, and included lower volumes than pre-September 11, 2001 conditions. Pedestrian volumes are shown in Appendix C.

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

CONSTRUCTION PERIOD (2006)

FUTURE COMMON TO ALL ALTERNATIVES

Pedestrian trips in the study area are expected to increase as commercial and residential projects are opened and as currently vacated buildings are reoccupied in the vicinity of the WTC site. Table 8D-4 summarizes pedestrian levels of service for the 2006 baseline conditions. (It should be noted that the baseline conditions include the trips to and from the temporary WTC PATH station, since it would be maintained in 2006.)

The east crosswalk at Church and Fulton Streets would operate at LOS E in the PM peak hour; this pedestrian movement experienced LOS E conditions following September 11, 2001, as discussed above. The west crosswalk at Church and Vesey Streets would operate at LOS F in the AM and PM peak hours, primarily due to the large volume of temporary WTC PATH station pedestrians accessing the Vesey Street bridge over Route 9A. The intersection of Church Street at Liberty Street would experience LOS E in the north crosswalk in the AM and PM peak hours, and LOS F and E in the west crosswalk in the AM and PM peak hours, respectively. These poor levels of service would result from temporary WTC PATH station pedestrians, who would originate from and be destined for points south and east of the WTC. They would primarily use the north crosswalk to go to or come from the east, and would use the west crosswalk to go to or come from the south. All other crosswalks would operate at acceptable levels of service.

The Route 9A pedestrian overpasses at Vesey and Liberty Streets, reconstructed after September 11, 2001, would be maintained throughout the construction period. The pedestrian overpasses would process additional pedestrian volumes due to temporary WTC PATH station trips and growth since the 2003 pedestrian counts.

NO ACTION ALTERNATIVE

The No Action Alternative would not result in construction of a Permanent WTC PATH Terminal. Thus, pedestrian operations in the study area would be unchanged from the baseline conditions presented in Table 8D-4.

PREFERRED ALTERNATIVE

During the construction period, pedestrian conditions would be nearly identical to those previously described for the No Action Alternative. Because construction of the Preferred Alternative would maintain pedestrian patterns from conditions following September 11, 2001, major shifts in pedestrian patterns would not be expected. Also, the construction activities would maintain access to NYCT subways and the temporary WTC PATH station.

The east side of the Route 9A (West Street) sidewalk would stay closed between Liberty and Vesey Streets during Route 9A reconstruction. Meanwhile, free-flow pedestrian walkways would be maintained on Liberty and Vesey Streets between the Route 9A pedestrian overpasses and Church Street during PATH/WTC construction. The width of the sidewalk on the west side of Church Street would be maintained to at least ten feet, while the area between Liberty and Vesey Streets would be for equipment storage and staging.

Table 8D-4
2006 Construction Period Baseline Pedestrian Level of Service

Location	AM Peak Hour	Midday Peak Hour	PM Peak Hour

North Crosswalk	E	C	E
East Crosswalk	C	B	D
South Crosswalk	C	B	B
West Crosswalk	F	C	E
Northwest Corner	N/A	N/A	N/A

Note: Refer to Figure 8D-1 for location numbers.

Currently, because of construction-related street closures at the WTC site, the West Broadway/Vesey Street and Greenwich Street/Liberty Street intersections do not have any conflict points with pedestrians. These pedestrians, similar to current conditions, would be diverted onto walkways to or from the Vesey and Liberty Street overpasses at Route 9A, separating them from construction activities and, therefore, conflicting vehicles or pedestrian traffic signals.

It has been assumed that during construction there would be limited at-grade pedestrian crossings of Route 9A at Vesey or Liberty Street (most likely construction workers), and the majority of pedestrian crossings would be made using the two pedestrian overpasses crossing Route 9A. These overpasses at Vesey and Liberty Streets, reconstructed after September 11, 2001, would be maintained throughout the construction period. They would process nearly identical pedestrian volumes when compared to conditions without the Preferred Alternative, and would operate at improved levels of service when compared to pre-September 11, 2001 conditions.

As described in Chapter 17, "Safety and Security," PANYNJ would implement measures to protect pedestrians, including temporary WTC PATH riders, during the construction period.

OPENING YEAR (2009)

FUTURE COMMON TO ALL ALTERNATIVES

As private development occurs on and near the WTC site, pedestrian activity in the study area will increase. Furthermore, the opening of a memorial and cultural facilities at the WTC site will attract visitors to the area during all periods of the day. These pedestrians will increase the demand for on-street facilities on and near the proposed Project Site.

NO ACTION ALTERNATIVE

Absent the Preferred Alternative, it is expected that the temporary WTC PATH station would continue to maintain service to the extent possible. However, as stated in Chapter 8, "PATH", Section A, increasing passenger volumes anticipated over time would place severe operating constraints on the temporary WTC PATH and projected WTC-bound PATH, passengers would be diverted to other modes of travel. Furthermore, on-street pedestrian circulation in the area would increase in the opening year with the completion of elements of LMDC's World Trade Center Memorial and Redevelopment Plan (Freedom Tower, retail and restaurants, Performing Arts Center, Memorial, and cultural land uses), and would likely exceed levels measured before September 11, 2001

PREFERRED ALTERNATIVE

The Preferred Alternative would have nine access points to the street and WTC concourse. Eight access points would be available within the WTC site and there would be an access point through a concourse connecting the WTC site with the World Financial Center via a pedestrian tunnel below Route 9A (see Figure 8D-2).

Hourly pedestrian volumes under the Preferred Alternative are illustrated in Appendix C. Complete pedestrian volume maps are included in the Technical Appendix. Table 8D-5 summarizes the projected future conditions in the opening year if the events of September 11, 2001 had not taken place and compares them to conditions under the Preferred Alternative.

Note: Refer to Figure 8D-1 for location numbers.

The proposed site plan for the WTC complex would extend Fulton Street westward from Church Street to Route 9A and extend Greenwich Street between Vesey and Liberty Streets, which would create additional pedestrian crossing areas at the Fulton Street intersections at Route 9A, Greenwich Street, and Church Street; the Greenwich Street intersections at Vesey Street/West Broadway; and at Cortlandt Street's extension from Church Street. These new crossings have been analyzed, with the exception of the Fulton Street at Route 9A intersection because of the proximity of the World Financial Center pedestrian concourse crossing under Route 9A, which is estimated to carry nearly all of Route 9A-crossing PATH riders.

The redevelopment of the WTC and the future memorial are expected to generate increased pedestrian circulation within the WTC and in crosswalks on Vesey, Church, and Liberty Streets. The redevelopment adds land uses such as a memorial, cultural facilities, retail, and a performing arts center, that were not included in the pre-September 11, 2001 program, which results in higher trip generation and pedestrian volumes.

The Preferred Alternative includes the WTC Memorial and Redevelopment Program in its background pedestrian volumes. The Preferred Alternative conditions were compared to the pre-September 11, 2001 projected future conditions, which included the WTC complex. Because the pre-September 11, 2001 WTC complex included fewer pedestrian volumes and less on-street circulation between land uses than the proposed WTC Memorial and Redevelopment Plan, the cumulative pedestrian volumes calculated for the build condition would be higher in many places than pre-September 11, 2001 projected future conditions. However, the on-street pedestrian trips to and from the Preferred Alternative would be lower than the pre-September 11, 2001 projected future conditions crossing Route 9A because of an improved connection to the World Financial Center. Pedestrian trips would also be higher at Vesey Street and West Broadway because of the destruction of the 7 WTC pedestrian overpass. Because of the unequal number of background trips generated by the pre-September 11, 2001 WTC complex and the proposed WTC Memorial and Redevelopment, it

was difficult to determine the impacts of the Preferred Alternative. Therefore, a different methodology for determining adverse impacts was employed.

The analyses below summarize pedestrian conditions by intersection, and identify crosswalks operating at unacceptable LOS E or F. The summaries identify whether these levels of service result from WTC Memorial and Redevelopment Plan background volumes or from the Preferred Alternative by assigning a percentage share of trips to the latter. Calculating this share of trips is achieved by dividing the number of trips to and from the Terminal by the total number of pedestrians crossing. In the summaries below, an adverse impact is defined as a location operating at LOS E or F, at which 50 percent or more of the total volume is associated with the Preferred Alternative.

Route 9A and Vesey Street

The Route 9A/Vesey Street east crosswalk would operate at LOS E during the midday peak hour. AM and PM peak hour levels of service would be acceptable. During the midday peak hour, PATH ridership is low while WTC shopping, tourism, and employee trip generation and circulation is high, so midday LOS E conditions are most likely not a result of PATH trips.

Route 9A and Liberty Street

The Route 9A/Liberty Street intersection would experience improved levels of service, most likely a benefit of the World Financial Center connection, which would improve access to Battery Park City for residents and the World Financial Center for commuters and shoppers.

West Broadway and Vesey Street

Before September 11, 2001, this intersection operated at acceptable levels of service because of the pedestrian overpass spanning Vesey Street west of West Broadway, which connected 6 and 7 WTC. In the opening year, the West Broadway/Vesey Street intersection would operate at LOS D and E during all peak hours because street crossings must be made at grade. Approximately 10 to 15 percent of these AM peak hour trips are project-generated. Thus, based on the impact criteria described above, this project would not require mitigation at this location.

Greenwich Street and Fulton Street

Several of the new Greenwich Street/Fulton Street crosswalks would operate at LOS E during specific peak hours, as described in Table 8D-5. Entrances to the WTC Memorial and cultural land uses, Performing Arts Center, Tower 2, and Wedge of Light Plaza are located adjacent to this intersection. There would be heavy on-street pedestrian flows between these uses and public transportation access on the south side of Fulton Street, such as subways and the Preferred Alternative. It is estimated that the share of the Preferred Alternative trips to 7 WTC and points north of Vesey Street would be approximately 20 to 30 percent. Thus, based on the impact criteria described above, this project would not require mitigation at this location.

Greenwich Street Midblock and Cortlandt Street

The new Greenwich Street midblock pedestrian crossing at Cortlandt Street would operate at acceptable levels of service during all peak hours. Project-generated trips using this crosswalk destined for the WTC Memorial, Tower 5, and points south of Liberty Street would be able to cross Greenwich Street using the pedestrian-only phase.

Greenwich Street and Liberty Street

The Greenwich Street/Liberty Street west crosswalk would operate at LOS E during the midday peak hour. During the midday peak hour, PATH ridership is low while WTC shopping, tourism, and employee trip generation and circulation is high, so midday LOS E conditions are most likely not a result of PATH trips.

Church Street and Vesey Street

The Church Street/Vesey Street east crosswalk would operate at LOS E during all peak hours, and the west crosswalk would operate at LOS E during the PM peak hour. These levels of service are generally similar to pre-September 11, 2001 projected future conditions, or worsened from LOS D to E. It is estimated that the share of project-generated trips to points north of Vesey and east of Church Streets would be approximately 15 to 25 percent. Thus, based on the impact criteria described above, this project would not require mitigation at this location.

Church Street and Fulton Street

The Dey Street connection between the WTC site and the Fulton Street Transit Center would be operational in the 2009 Opening Year. As a result, pedestrians would be diverted from the east-west crossings at the intersection of Fulton and Church Streets, and the intersection would experience an improved level-of-service as compared to pre-September 11, 2001 conditions.

Church Street and Dey Street

As noted above, the Dey Street connection between the WTC site and the Fulton Street Transit Center would be operational in the 2009 Opening Year. The new concourse would divert pedestrians from the east-west crossings at the intersection of Dey and Church Streets, and the intersection would experience an improved level-of-service as compared to pre-September 11, 2001 conditions.

Church Street and Cortlandt Street

The Dey Street connection would also divert pedestrians from the east-west crossings at the intersection of Cortlandt and Church Streets, and the intersection would experience an improved level-of-service as compared to pre-September 11, 2001 conditions.

Church Street and Liberty Street

For access to the Financial District, pedestrians would use Permanent WTC PATH Terminal exits in the vicinity of WTC Towers 3 and 4, and cross Church and Liberty Streets at street level. Based on surveys conducted before September 11, 2001, it is anticipated that 40 percent of alighting AM peak hour PATH trips are destined for the Financial District.

In the AM, midday and PM peak hours, approximately 4,070, 70, and 1,890 new trips would be added to the totals of 5,840, 3,170 and 5,110 trips, respectively, resulting in increases of up to 70 percent.

The loss in area per person would range from 1 to 17 SFP in the crosswalks, and from 2.8 to 17.7 in the northwest corner reservoir. The northwest corner reservoir LOS F in the AM peak hour would congest pedestrian flows when pedestrians are queued to cross away from the WTC/PATH site in the west and north crosswalks, and block pedestrians crossing inbound from the northeast and southwest corners of the intersection. Pedestrians normally crossing at Church and Liberty Street may divert to the Cortlandt or Cedar Street intersections, or illegally cross

Church Street between Liberty and Cortlandt Streets. Pedestrians circulating through the northwest corner reservoir during surge conditions require more physical space than could be afforded in that area, which could force pedestrians to wait on the street in Liberty or Church Street vehicular travel lanes.

Mitigation to restore LOS E conditions would include widening the north and west crosswalks by 10 feet each, making them 25 feet wide. To restore the northwest corner reservoir LOS F conditions to LOS E conditions would include widening the north and west sidewalks by five feet each.

Given that the Preferred Alternative would generate more than 50 percent of the volume at this location, mitigation measures would be necessary as part of this project.

DESIGN YEAR (2025)

FUTURE COMMON TO ALL ALTERNATIVES

Independent of the Preferred Alternative, the on-street pedestrian circulation in the design year would increase beyond opening year levels with the completion of the WTC office and hotel land uses and the development of Battery Park City Site 26. These levels would also exceed conditions measured before September 11, 2001.

NO ACTION ALTERNATIVE

For analysis purposes, it was assumed that absent the Preferred Alternative, projected WTC-bound PATH passengers would be diverted to other modes of travel. Because on-street connections to mass transit located away from the WTC site would have to be made, on-street pedestrian conditions under the No Action Alternative would likely be worse than prior to September 11, 2001. The Permanent WTC PATH Terminal's purpose of serving as a central transit hub for Lower Manhattan would be negated, since PATH passengers would be diverted to overloaded NJ Transit commuter trains and NYCT subways; additional NY Waterway ferries would be needed; and additional passenger vehicle, taxi, express bus, and van trips would increase traffic on NYCDOT and NYSDOT roadways. These cumulative diversions would all increase on-street pedestrian circulation in Lower Manhattan.

Conditions described for the No Action Alternative in the opening year would worsen substantially by the design year. AM peak hour WTC Memorial and Redevelopment trips would increase over 100 percent from approximately 15,000 to 35,000 people per hour. The increased volumes in the design year may result in deteriorated levels of service at many analysis locations.

Without the sub-grade Route 9A connection, which is proposed as part of the Preferred Alternative, at-grade pedestrian activity will increase along Route 9A and its cross streets. Because ferry connections are made west of Route 9A, deteriorated levels of service on Route 9A could occur. Levels of service could deteriorate on Church Street between Liberty and Vesey Streets due to the locations of express bus routes and subway stations east of the WTC site. Auto and commuter van activity will increase and will worsen pedestrian levels of service because passenger drop-offs will occur adjacent to Liberty, Vesey, and Church Streets. As compared to the Preferred Alternative, the No Action Alternative would increase on-street pedestrian flows and worsen crosswalk congestion, necessitating additional mitigation to ensure proper circulation.

PREFERRED ALTERNATIVE

The hourly volumes representing pedestrians using the Permanent WTC PATH Terminal and the on-street pedestrian network in the design year are illustrated in Appendix C. Table 8D-6 summarizes projected future conditions in the design year if the events of September 11, 2001 had not taken place and compares them to conditions under the Preferred Alternative. Similar to the opening year conditions, at the Church and Liberty Street intersection, the northwest corner reservoir and all crosswalk levels of service in all peak hours deteriorate substantially.

Route 9A and Vesey Street

The Route 9A/Vesey Street east crosswalk would operate at LOS E during the midday peak hour. AM and PM peak hour levels of service would be acceptable. During the midday peak hour, PATH ridership is low while WTC shopping, tourism, and employee trip generation and circulation is high, so midday LOS E conditions are most likely not a result of PATH trips.

Route 9A and Liberty Street

The Route 9A/Liberty Street intersection would operate at acceptable levels of service during the AM, midday, and PM peak hours.

West Broadway and Vesey Street

Before September 11, 2001, this intersection operated at acceptable levels of service because of the pedestrian overpass spanning Vesey Street west of West Broadway, which connected 6 WTC to 7 WTC. In the opening year, the West Broadway/Vesey Street intersection would operate at LOS D, E, and F during all peak hours because street crossings must be made at grade. Approximately 10 to 15 percent of the AM peak hour trips using these crosswalks are project-generated trips destined to points north of Vesey Street including 7 WTC. Thus, based on the impact criteria described above, this project would not require mitigation at this location.

Greenwich Street and Fulton Street

All crosswalks at the new Greenwich and Fulton Street intersection would operate at LOS D, E, or F during all peak hours. Entrances to the WTC Memorial and cultural land uses, Performing Arts Center, Tower 2, and Wedge of Light Plaza are located adjacent to this intersection. There would be heavy on-street pedestrian flows between these uses and public transportation access on the south side of Fulton Street, such as subways and PATH. It is estimated that the share of project-generated trips to 7 WTC and points north of Vesey Street would be approximately 20 to 30 percent. Thus, based on the impact criteria described above, this project would not require mitigation at this location.

South Crosswalk	E	D	B	C	D	C
West Crosswalk	F	E	D	C	E	E
Northwest Corner	F	E	F	C	F	D

Note: Refer to Figure 8D-1 for location numbers.

Greenwich Street Midblock and Cortlandt Street

The new Greenwich Street midblock pedestrian crossing at Cortlandt Street would operate at acceptable levels of service during all peak hours. Project-generated trips using this crosswalk destined for the WTC Memorial, Tower 5, and points south of Liberty Street would be able to cross Greenwich Street using the pedestrian-only phase.

Greenwich Street and Liberty Street

All crosswalks at the Greenwich Street/Liberty Street intersection would operate at LOS D, E, or F during all peak hours. Approximately 5 to 10 percent of peak hour trips using these crosswalks are project-generated trips destined to points south of Liberty Street including Tower 5. Thus, based on the impact criteria described above, this project would not require mitigation at this location.

Church Street and Vesey Street

The Church Street/Vesey Street east and west crosswalks would operate at LOS E during all peak hours, and the south crosswalk would operate at LOS E during the PM peak hour. These levels of service are generally similar to pre-September 11, 2001 projected future conditions, or worsened from LOS D to E. The Preferred Alternative would generate 20 to 25 percent of trips to points north of Vesey and east of Church Streets. Thus, based on the impact criteria described above, this project would not require mitigation at this location.

Church Street and Fulton Street

The Church Street/Fulton Street north and west crosswalks would operate at LOS E during the midday peak hour, the east crosswalk at LOS E during the AM and PM peak hours, and the

south crosswalk at acceptable levels of service during all peak hours. It is estimated that the share of project-generated trips to points east of Church Street would be less than 5 percent. Thus, based on the impact criteria described above, this project would not require mitigation at this location.

Church Street and Dey Street

The Dey Street concourse between the WTC site and the Fulton Street Transit Center would divert pedestrians from the east-west crossings at the intersection of Dey and Church Streets, and the intersection would experience an improved level-of-service as compared to pre-September 11, 2001 conditions.

Church Street and Cortlandt Street

The Dey Street connection would also divert pedestrians from the east-west crossings at the intersection of Cortlandt and Church Streets, and the intersection would experience an improved level-of-service as compared to pre-September 11, 2001 conditions.

Church Street and Liberty Street

Pedestrians would use Terminal exits in the vicinity of WTC Towers 3 and 4, and cross Church Street and Liberty Streets at street level, as noted under opening year conditions. Based on surveys conducted before September 11, 2001, it is anticipated that 40 percent of alighting AM peak hour PATH trips are destined for the Financial District.

In the AM, midday, and PM peak hours, approximately 4,490, 90 and 2,010 new trips would be added to the totals of 8,420, 4,980 and 7,050 trips, respectively, resulting in increases of up to 50 percent.

At crosswalk conditions in all peak hours at this location, LOS F conditions at the north and west crosswalks could cause pedestrians to spill into the opposing traffic travel lanes during the pedestrian signal. The loss in area per person would range from 1 to 10 SFP in the crosswalks, and from 1.3 to 12.4 in the northwest corner reservoir. The northwest corner reservoir LOS F in the AM peak hour would congest pedestrian flows when pedestrians are queued to cross away from the WTC/PATH site in the west and north crosswalks, and block pedestrians crossing inbound from the northeast and southwest corners of the intersection. Pedestrians normally crossing at Church and Liberty Street may divert to the Cortlandt or Cedar Street intersections, or illegally cross Church Street between Liberty and Cortlandt Streets. Pedestrians circulating through the northwest corner reservoir during surge conditions require more physical space than could be afforded in that area, which could force pedestrians to wait on the street in Liberty or Church Street vehicular travel lanes.

Mitigation to restore LOS E conditions would include widening the north and west crosswalks by 11 feet each, making them 26 feet wide. To restore the northwest corner reservoir LOS F conditions would include widening the north and west sidewalks by six feet each.

Given that the Preferred Alternative would generate more than 50 percent of the volume at this location, mitigation measures would be necessary as part of this project.

E. MITIGATION

The overall effect of the Preferred Alternative on the on-street pedestrian network would be an improvement over conditions that existed with the pre-September 11, 2001 WTC PATH

Terminal. The off-street connections to the Fulton Street Transit Center and many of the redeveloped WTC land uses would reduce pedestrian trips made by PATH riders that would be made on the street.

CONSTRUCTION PERIOD (2006)

During the construction period, pedestrian conditions would be nearly identical to the No Action conditions, and no specific mitigation is necessary. Because the construction of the Preferred Alternative would maintain pedestrian patterns from conditions following September 11, 2001, major shifts in pedestrian patterns are not expected. When considering the cumulative construction impacts on the pedestrian network discussed in Chapter 15, "Cumulative Effects," coordination between lead agencies would help ensure that pedestrian crossing patterns are maintained and pedestrian safety needs are accommodated.

However, to ensure the safe and convenient movement of pedestrians during the construction period, PANYNJ would implement Environmental Performance Commitments (EPCs) as part of the Preferred Alternative. As described in Chapter 8, Section B, "Vehicular Traffic and Parking," these EPCs would include a Maintenance and Protection of Traffic (MPT) Plan as well as communication tools to inform and protect the public.

OPENING YEAR (2009)

The opening year levels of service were compared to projected future conditions based on pre-September 11, 2001 volumes. Based on the criteria described above, the Preferred Alternative would result in an adverse impact at the intersection of Church and Liberty Streets.

The location of the Terminal's access points combined with the large volumes generated by the World Trade Center Memorial and Redevelopment Plan would adversely impact some crosswalks. To assess the proportion of impacts from this project, a percent share of trips attributed to the Preferred Alternative was calculated for crosswalks operating at unacceptable LOS E or F. This calculation divides the number of trips destined to and from the Permanent WTC PATH Terminal by the total number of pedestrians. Table 8D-7 summarizes adversely impacted crosswalks and lists mitigation measures, followed by the percentage share of trips attributed to the Preferred Alternative in relation to total pedestrian volumes.

Mitigation is necessary to restore some crosswalks in the Preferred Alternative's conditions to the levels of service calculated in projected future conditions based on pre-September 11, 2001 volumes. The measures suggested to mitigate adverse impacts include increases in crosswalk widths to improve levels of service at selected crosswalks on West Broadway, and on Greenwich, Church, Vesey, Fulton, and Liberty Streets, which would primarily be the result of background volumes generated by the WTC Memorial and Redevelopment Plan. The measures suggested to mitigate adverse impacts primarily due to the Preferred Alternative at the intersection of Church and Liberty Streets would consist of widening crosswalks by ten feet and sidewalks by five feet. To avoid subsequent impacts to vehicular traffic operations, it is recommended that sidewalks be widened within the limits of the WTC site. Table 8D-7 provides summaries of impacted intersections and mitigation.

It should be noted that additional or more aggressive measures may be required to mitigate the project's effects in the design year, as described below. FTA and PANYNJ would ensure that all of the required mitigation for both the opening and design year impacts is implemented in a single phase in or about the opening year.

Table 8D-7
Pedestrian Impacts and Mitigation Measures

Location	Mitigation Measure	Percent share of volumes attributed to the Preferred Alternative
Route 9A at Vesey Street		
North Crosswalk	No impact; no action needed	
East Crosswalk	No impact; no action needed	
South Crosswalk	No impact; no action needed	
Route 9A at Liberty Street		
North Crosswalk	No impact; no action needed	
East Crosswalk	No impact; no action needed	
South Crosswalk	No impact; no action needed	
West Broadway at Vesey Street		
North Crosswalk	Widen crosswalk	10-15 percent PATH effects
East Crosswalk	Widen crosswalk	10-15 percent PATH effects
South Crosswalk	Widen crosswalk	10-15 percent PATH effects
West Crosswalk	Widen crosswalk	10-15 percent PATH effects
Greenwich Street at Fulton Street		
North Crosswalk	Widen crosswalk	20-30 percent PATH effects
East Crosswalk	Widen crosswalk	20-30 percent PATH effects
South Crosswalk	Widen crosswalk	20-30 percent PATH effects
West Crosswalk	Widen crosswalk	20-30 percent PATH effects
Greenwich Street Midblock		
North Crosswalk	No impact; no action needed	
Greenwich Street at Liberty Street		
North Crosswalk	Widen crosswalk	5-10 percent PATH effects
East Crosswalk	Widen crosswalk	5-10 percent PATH effects
South Crosswalk	Widen crosswalk	5-10 percent PATH effects
West Crosswalk	Widen crosswalk	5-10 percent PATH effects
Church Street at Vesey Street		
North Crosswalk	No impact; no action needed	
East Crosswalk	Widen crosswalk	5-10 percent PATH effects
South Crosswalk	No impact; no action needed	
West Crosswalk	Widen crosswalk	25-35 percent PATH effects
Church Street at Fulton Street		
North Crosswalk	Widen crosswalk	0-5 percent PATH effects
East Crosswalk	Widen crosswalk	0-5 percent PATH effects
South Crosswalk	Widen crosswalk	0-5 percent PATH effects
West Crosswalk	Widen crosswalk	0-5 percent PATH effects
Church Street at Dey Street		
North Crosswalk	No impact; no action needed	
East Crosswalk	No impact; no action needed	
South Crosswalk	No impact; no action needed	

Table 8D-7 (cont'd)
Pedestrian Impacts and Mitigation Measures

Location	Mitigation Measure	Percent share of volumes attributed to the Preferred Alternative
Church Street at Cortlandt Street		
North Crosswalk	No impact; no action needed	
East Crosswalk	No impact; no action needed	
South Crosswalk	No impact; no action needed	
Church Street at Liberty Street		
North Crosswalk	Widen crosswalk by 10 feet	55 percent PATH effects
East Crosswalk	No impact; no action needed	
South Crosswalk	No impact; no action needed	
West Crosswalk	Widen crosswalk by 10 feet	75 percent PATH effects
Northwest Corner	Widen sidewalks by 5 feet each	75 percent PATH effects

DESIGN YEAR (2025)

The design year levels of service were compared to projected future conditions based on pre-September 11, 2001 volumes. Mitigation would be necessary at adversely impacted crosswalks at the West Broadway and Vesey Street intersection, Greenwich Street intersections at Fulton and Liberty Streets, and Church Street intersections at Vesey and Fulton Streets. The mitigation measures include widening crosswalks. At the intersection of Liberty and Church Streets, LOS F conditions would result on the northwest corner reservoir, and in the north and west crosswalks in the AM peak hour. More aggressive mitigation would be required at this location, consisting of widening crosswalks by 11 feet and sidewalks by six feet. Thus, crosswalks and sidewalks would need to be one foot wider than was presented for the opening year. The mitigation measures presented for other impacts in the opening year section would also mitigate all design year impacts. PANYNJ will coordinate with LMDC and NYCDOT to implement the recommended pedestrian improvements in the vicinity of the WTC site. ✶

A. INTRODUCTION

By fostering the use of mass transit to Lower Manhattan, the Preferred Alternative would have a beneficial effect on regional air quality in the New York Metropolitan Area (NYMA). Without the Terminal, it is expected that vehicles–miles–traveled in the metropolitan area would increase as some portion of the transit riders shift to automobiles for their daily commute (see Chapter 8B, "Vehicular Traffic and Parking"); this, in turn, would result in an increase in vehicle–related emissions such as carbon monoxide, nitrogen oxides, particulate matter, and volatile organic compounds, as discussed later in this chapter.

While the Preferred Alternative would result in a net air quality benefit to the NYMA, the pre–September 11, 2001 conditions also included that same benefit. Furthermore, since the Preferred Alternative would not, in itself, result in an increased ridership when compared to the forecasts prepared before September 11, 2001 condition, there would be no change in local air quality in the vicinity of the Project Site or stations in New Jersey. The Preferred Alternative would essentially provide better service to demand that was forecasted to have occurred under any condition. Moreover, as discussed in Chapter 8B, Chapter 8, Section B, "Vehicular Traffic and Parking," a very small percentage of PATH riders generated vehicle trips at the WTC site. Therefore, the Preferred Alternative would result in a very small number of vehicle trips in the vicinity of the WTC, which is consistent with pre–September 11, 2001 conditions. The Preferred Alternative would also use electricity, steam, and/or river water cooling to provide for energy needs and would not require any on–site combustion of pollution–generating fossil fuels.

The greatest potential for adverse impacts on ambient air quality from the Preferred Alternative is during the construction phase. A detailed assessment of the potential construction–related impacts to air quality is included in this chapter. The cumulative effects of the Preferred Alternative's construction along with other projects planned in Lower Manhattan are discussed in Chapter 15, "Cumulative Effects." Furthermore, as described in Chapter 2, "Project Alternatives," the Port Authority of New York and New Jersey (PANYNJ) has committed to a series of environmentally friendly ("green") design measures, including energy conservation measures, which would result in an overall reduction in pollutant emissions.

B. METHODOLOGY

POLLUTANTS FOR ANALYSIS

In the NYMA, ambient concentrations of carbon monoxide are predominantly influenced by mobile source emissions. Emissions of particulate matter and nitrogen oxides come from both mobile and stationary sources; emissions of sulfur dioxide are associated mainly with stationary sources. Ozone, one of the region's most problematic air pollutants, is not emitted directly in any substantial quantity, but is formed in the atmosphere by a series of complex chemical reactions involving mainly volatile organic compounds and nitrogen oxides.

CARBON MONOXIDE

Carbon monoxide (CO), a colorless and odorless gas, is produced in the urban environment primarily by the incomplete combustion of gasoline and other fossil fuels. In an urban area, approximately 80 to 90 percent of CO emissions are from motor vehicles. CO concentrations can vary greatly over relatively short distances. Elevated concentrations are usually limited to crowded intersections, heavily traveled and congested roadways, or parking lots or garages. Consequently, CO concentrations must be predicted on a local scale (microscale).

While operation of the Preferred Alternative would not result in any long–term increase in vehicular traffic at local intersections, a microscale analysis of the impact of construction on CO concentrations at affected intersections has been performed.

NITROGEN OXIDES AND OZONE

Nitrogen oxides (nitrogen oxide, NO, and nitrogen dioxide, NO_2—together NO_x) are of principal concern because of their role, together with volatile organic compounds (VOCs), as precursors in the formation of ozone. While there is a standard for average annual NO_2 concentrations, it is normally examined only for large fossil fuel energy sources. Ozone is formed through a series of reactions that take place in the atmosphere in the presence of sunlight. Because the reactions are slow and occur as the pollutants are diffusing downwind, elevated ozone levels are often found many miles from sources of the precursor pollutants. The effects of NO_x and VOC emissions from mobile sources are therefore generally examined on a regional basis, together with the emission of these pollutants from stationary sources. The change in regional mobile source emissions of these pollutants is related to the total number of vehicle trips and vehicle miles of travel throughout the NYMA, which is designated as a severe non–attainment area for ozone by the United States Environmental Protection Agency (EPA) (i.e., counties in Northern New Jersey, New York City, Long Island, Southern Hudson Valley, and western Connecticut).

Operation of the Preferred Alternative would result in a long–term reduction in vehicular traffic at local intersections; however, its construction would result in temporary emission of ozone precursors from on–road and on–site engines. A regional (mesoscale) analysis has been performed for both sources.

LEAD

Lead emissions in air are principally associated with industrial sources and motor vehicles that use gasoline containing lead additives. Most U.S. vehicles produced since 1975, and all produced after 1980, are designed to use unleaded fuel. As these newer vehicles have replaced the older ones, motor–vehicle–related lead emissions have decreased. As a result, ambient concentrations of lead have declined substantially. Nationally, the average measured atmospheric lead level in 1985 was only about one–quarter the level of 1975.

In 1985, EPA announced new rules drastically reducing the amount of lead permitted in leaded gasoline. Monitoring results indicate that this action has been effective in substantially reducing atmospheric lead levels. Even at locations in the New York City area where traffic volumes are very high, atmospheric lead concentrations are far below the national standard of 1.5 micrograms per cubic meter (3–month average).

No substantial sources of lead are associated with the Preferred Alternative, and, therefore, analysis was not warranted.

RESPIRABLE PARTICULATE MATTER—PM_{10} AND $PM_{2.5}$

Particulate matter (PM) is a broad class of air pollutants that includes discrete particles of a wide range of sizes and chemical compositions, as either liquid droplets (aerosols) or solids suspended in the atmosphere. The constituents of PM are both numerous and varied, and they are emitted by a wide variety of sources (both natural and anthropogenic). Natural sources include the condensed and reacted forms of natural organic vapors; salt particles resulting from the evaporation of sea spray; wind–borne pollen, fungi, molds, algae, yeasts, rusts, bacteria, and debris from live and decaying plant and animal life; particles eroded from beaches, soil and rock; particles emitted from volcanic and geothermal eruptions and from forest fires. Major anthropogenic sources include the combustion of fossil fuels (e.g., vehicular exhaust, power generation, home heating), chemical and manufacturing processes, all types of construction, agricultural activities, as well as wood–burning stoves and fireplaces. Particulate matter also acts as a substrate for the adsorption of other pollutants, often toxic and some likely carcinogenic compounds.

Fine particulate matter, or $PM_{2.5}$, are fine particles with an aerodynamic diameter of less than or equal to 2.5 micrometers. This smaller fraction of the particle size range has the ability to reach the lower regions of the respiratory tract, delivering with it other compounds that adsorbed to the surfaces of the particles, and is also extremely persistent in the atmosphere. $PM_{2.5}$ is mainly derived from combustion material that has volatilized and then condensed to form primary particulate matter (often soon after the release from an exhaust pipe or stack) or from precursor gases reacting in the atmosphere to form secondary particulate matter. Diesel–powered vehicles, especially heavy trucks and buses, are a substantial source of respirable PM; PM concentrations may, consequently, be locally elevated near roadways with high volumes of heavy diesel–powered vehicles.

A microscale analysis of $PM_{2.5}$ and PM_{10} (particles with an aerodynamic diameter of less than or equal to 10 micrometers) has been conducted for the construction phase of the Preferred Alternative, which would include potential sources such as diesel engine and fugitive dust emissions.

SULFUR DIOXIDE

Sulfur dioxide (SO_2) emissions are primarily associated with the combustion of sulfur–containing fuels: oil and coal.

Due to the federal restrictions on the sulfur content in diesel fuel for on–road vehicles, no substantial quantities are emitted from vehicular sources. Additionally, during the construction phase, all on–site nonroad engines would be employing ultra low sulfur diesel (ULSD), which would emit very small amounts of SO_2. Therefore, analysis of SO_2 was not warranted.

AIR QUALITY STANDARDS

NATIONAL AND STATE AIR QUALITY STANDARDS

As required by the Clean Air Act, primary and secondary NAAQS have been established for six major air pollutants: CO, NO_2, ozone, respirable PM, SO_2, and lead. The primary standards protect public health and represent levels at which there are no known substantial effects on human health. The secondary standards are intended to protect the nation's welfare, and account for air pollutant effects on soil, water, visibility, materials, vegetation, and other aspects of the

environment. For NO_2, ozone, lead and PM, the primary and secondary standards are the same; there is no secondary standard for CO. EPA recently promulgated additional NAAQS which became effective September 16, 1997: a new 8–hour standard for ozone, which will replace the existing 1–hour standard, and in addition to retaining the PM_{10} standards, EPA adopted 24–hour and annual standards for $PM_{2.5}$. The standards for these pollutants are presented in Table 9–1. These standards have also been adopted as the ambient air quality standards for New York State.

INTERIM GUIDANCE CRITERIA REGARDING $PM_{2.5}$ IMPACTS

New York State Department of Environmental Conservation (NYSDEC) has published a policy to provide interim direction for evaluating $PM_{2.5}$ impacts. This draft policy would apply only to facilities applying for permits or major permit modification under the State Environmental Quality Review Act (SEQRA) that emit 15 tons of PM_{10} or more annually. The interim draft policy states that such a project will be deemed to have a potential adverse impact if the project's maximum predicted impacts are predicted to increase $PM_{2.5}$ concentrations by more than 0.3 $\mu g/m^3$ averaged annually or more than 5 $\mu g/m^3$ on a 24–hour basis. Projects that exceed either the annual or 24–hour threshold will be required to prepare a written assessment of the severity of the impacts, to evaluate alternatives, and to employ reasonable and necessary mitigation measures to minimize the $PM_{2.5}$ impacts to the maximum extent practicable. The Preferred Alternative as a whole was not predicted to have emissions of more than 15 tons per year at any stage, and is not a "source" requiring a permit from NYSDEC.

New York City Department of Environmental Protection (NYCDEP) is currently recommending interim guidance criteria for evaluating the potential $PM_{2.5}$ impacts from projects in New York City. The interim guidance criteria currently employed by NYCDEP[1] for determination of adverse impacts from $PM_{2.5}$ are as follows:

- Predicted 24–hour (daily) average increase in $PM_{2.5}$ concentrations greater than 5 $\mu g/m^3$ at a discrete location of public access, either at ground or elevated levels (microscale analysis); and
- Predicted annual average increase in ground–level $PM_{2.5}$ concentrations greater than 0.1 $\mu g/m^3$ on a neighborhood scale (i.e., the annual increase in concentration representing the average over an area of approximately 1 square kilometer, centered on the location where the maximum impact is predicted for stationary sources; or at a distance from a roadway corridor similar to the minimum distance defined for locating background monitoring stations).

In order to put these levels in context, the average bias (difference) between 24–hour average $PM_{2.5}$ concentrations measured at collocated monitors (two identical monitors at the same location) in four monitoring stations in New York City from January to December 2000 ranged from 0.41 to 0.83 $\mu g/m^3$. Monitored changes in concentration that would be lower than these levels could not conclusively indicate any change in concentration.

The above NYCDEP draft interim guidance criteria have been used for the purpose of evaluating the impacts of the Preferred Alternative on $PM_{2.5}$ concentrations from mobile sources, and determine the need to mitigate particulate matter emissions from the Preferred Alternative.

STATE IMPLEMENTATION PLAN (SIP)

The Clean Air Act, as amended in 1990 (CAA) defines non–attainment areas (NAA) as geographic regions that have been designated as not meeting one or more of the NAAQS. When an area is designated as non–attainment by EPA, the state is required to develop and implement a State Implementation Plan (SIP) for each applicable NAAQS, which is a state's plan on how it will meet the NAAQS under the deadlines established by the CAA.

EPA has re–designated New York City as in attainment for CO. The CAA requires that a maintenance plan ensure continued compliance with the CO NAAQS for former non–attainment areas. New York City is also committed to implementing site–specific control measures throughout the city to reduce CO levels, should unanticipated localized growth result in elevated CO levels during the maintenance period.

Manhattan has been designated as a moderate NAA for PM_{10}. On December 17, 2004, EPA took final action designating the five boroughs of New York City as well as Nassau, Suffolk, Rockland, Westchester and Orange counties as $PM_{2.5}$ non-attainment areas under the CAA. State and local governments are required to develop implementation plans (by early 2008) that include measures designed to attain the standards in or after 2010.

Nassau, Rockland, Suffolk, Westchester and the five counties of New York City have been designated as severe non–attainment for ozone 1–hour standard. In November 1998, New York State submitted its *Phase II Alternative Attainment Demonstration for Ozone*, which was finalized and approved by EPA effective March 6, 2002, addressing attainment of the one–hour ozone NAAQS by 2007. New York State has recently submitted revisions to the SIP; these SIP revisions included additional emission reductions that EPA requested to demonstrate attainment of the standard, and an update of the SIP estimates using two new EPA models—the mobile source emissions model MOBILE6, and the non–road emissions model NONROAD—which have been updated to reflect current knowledge of engine emissions, and the latest mobile and non–road engine emissions regulations. On April 15, 2004, EPA designated these same counties as moderate non–attainment for the new 8–hour ozone standard which became effective as of June 15, 2004 (the entire Orange county was moved to the Poughkeepsie moderate non–attainment area for 8–hour ozone). EPA will revoke the 1–hour standard in June, 2005; however, the specific control measures for the 1–hour standard included in the SIP will be required to stay in place until the 8–hour standard is attained. The discretionary emissions reductions in the SIP would also remain but could be revised or dropped based on modeling. A new SIP for ozone will be adopted by the state no later than June 15, 2007, with a target attainment deadline of June 15, 2010.

TRANSPORTATION CONFORMITY

The conformity requirements of the Clean Air Act and regulations promulgated thereunder (conformity requirements) limit the ability of Federal agencies to assist, fund, permit, and approve transportation projects that do not conform to the applicable SIP. An area's metropolitan planning organization, which is the entity responsible for transportation planning, together with the State, are responsible for demonstrating conformity of metropolitan long–range transportation plans and transportation improvement programs. The U.S. Department of Transportation (USDOT) has final approval authority over the conformity of plans and transportation improvement programs. Conformity determinations for FTA projects must be made according to the requirements of 40 CFR Part 93.

At this time, as a result of the terrorist attacks of September 11, 2001, and the loss of New York Metropolitan Transportation Council (NYMTC's) files containing regional transportation and air quality data, combined with the damage incurred to the downtown mass transit system, the conformity requirements for the NYMA have been temporarily waived until September 30, 2005, pursuant to Public Law 107–230; Stat. 1469, enacted October 1, 2002. As part of the waiver process, project sponsors are to consult with the Interagency Consultation Group (ICG) to determine if the Preferred Alternative would be considered regionally significant and if additional air quality analysis is required during the waiver period. PANYNJ consulted with the ICG in February 2004, and the ICG has determined that in the absence of the waiver, this project would be exempt from conformity analysis requirements in accordance with 40 CFR 93.127. The ICG also agreed that a mesoscale analysis is not required.

MICROSCALE AIR QUALITY ANALYSIS METHODOLOGY

OVERVIEW

The air quality analysis in this EIS focuses on the potential adverse impacts during construction of the proposed WTC Permanent PATH Terminal. The cumulative air quality analysis in Chapter 15, "Cumulative Effects," applies the same procedures discussed below to a number of major projects assumed to be under construction simultaneously. In addition, regional (mesoscale) emissions inventories were prepared to determine the predicted direct and indirect emissions during construction, and predicted direct and indirect emissions savings attributable to the operation of the Terminal.

During construction, the potential effects on ambient air quality in the study area are the sum of three distinct sources of air pollutant emissions. The three sources are:

- On Road mobile sources (CO and PM)
- Construction equipment (CO, NO_2 and PM)
- Fugitive dust (PM only)

Mobile sources are the on–road construction vehicles (transporting materials or removing debris) traveling to and from the site, as well as their effects (i.e., increased congestion) on the base vehicular traffic traveling on the same roads. The construction equipment includes all of the fossil–fueled machinery that would be necessary to complete each element of the Preferred Alternative in the 2006 analysis year. Fugitive dust emissions are a result of activities that disturb material likely to result in the release of particulate matter. Examples of this type of emission include excavation, demolition, and vehicular traffic on paved or unpaved surfaces.

It is important to include each of these sources since they may act in concert to yield elevated levels of air pollutants. For example, while the particulate matter in diesel exhaust mostly consists of $PM_{2.5}$ and the fugitive dust from earth–moving activities are generally greater in size that PM_{10}, there is some contribution of $PM_{2.5}$ from the latter.

The following sections describe the methodologies used for each of the analyses described above.

ANALYSIS OF ON-ROAD MOBILE SOURCES

To compare estimated CO concentrations from the Preferred Alternative with the national ambient air quality standards for CO (which are based on 1– and 8–hour averages of CO

concentrations), estimates of maximum construction-related concentrations for these same periods must be prepared. Since experience in the study area has been that violations of the 1–hour CO standard are extremely rare, the CO analysis for this study focuses on determining the maximum predicted 8–hour CO concentrations.

Similarly, analyses of PM_{10} and $PM_{2.5}$ were conducted for the 24–hour and annual average conditions.

The on–road analyses for the Preferred Alternative are based on a modeling approach approved by EPA that has been widely employed for evaluating air quality impacts of projects in New York City, New York State, and throughout the country. Some additional, newer procedures for modeling $PM_{2.5}$ that have been developed in coordination with NYCDEP are also used. A series of worst–case assumptions relating to meteorology, traffic, and background concentration levels, were used as inputs. This approach results in a conservative estimate of expected air quality impacts caused by the Preferred Alternative and the resulting total pollutant concentrations.

Dispersion Models for Microscale Analyses

At all sites selected for CO analysis, maximum predicted 8–hour average CO concentrations were determined using EPA's CAL3QHC model[1], Version 2.0. The CAL3QHC model is a Gaussian dispersion model, which assumes that the dispersion of pollutants downwind of a pollution source follows a Gaussian (or normal) distribution, and is designed specifically for predicting CO concentrations along roadway segments.

Ambient concentrations of PM were computed at the selected receptor sites using the more refined version, CAL3QHCR. This version of the model can utilize hourly traffic and meteorology data, and is therefore more appropriate for calculating 24–hour and annual average concentrations. Tier II analysis, which includes the modeling of hour–by–hour concentrations based on hourly traffic data and 5–years of monitored hourly meteorological data, was performed to predict maximum 24–hour and annual average PM levels.

Worst–Case Meteorological Conditions

In general, the transport and concentration of pollutants from vehicular sources are influenced by three principal meteorological factors: wind direction, wind speed, and atmospheric stability, which accounts for the effects of dispersion or mixing in the atmosphere.

The CAL3QHC CO computations were performed using a wind speed of one meter per second, and stability class D, representative of neutral conditions in New York City. At each receptor location, the wind angle that maximized the pollutant concentrations was used in the analysis regardless of frequency of occurrence.

The CAL3QHCR Tier II PM analyses utilized monitored hourly meteorological data from LaGuardia Airport station in the years 1998–2002. All hours are modeled, and the highest resulting concentration for any averaging time is presented.

Vehicle Emissions Data

Vehicular exhaust emission factors were computed using the EPA Mobile Source Emissions Model, MOBILE6.2[1]. This is the latest, recently released emissions model, capable of calculating engine emission factors for various vehicle types, based on the fuel type (gas, diesel, or alternative technologies), meteorological conditions, vehicle speeds, roadway types, number of starts per day and engine soak time, and various other factors that influence emissions, such as inspection maintenance programs.

Vehicle classification data were based on field studies and data obtained from other traffic studies as discussed in Chapter 8, "Transportation." Emission estimates were based on guidance from NYCDEP and NYSDEC on the appropriate credits to be used in the MOBILE6.2 model to accurately reflect the inspection and maintenance program. The inspection and maintenance programs require inspections of automobiles and light trucks to determine if pollutant emissions from the vehicles' exhaust systems are below acceptable emission standards. Vehicles failing the emissions test must undergo maintenance and pass a repeat test to be registered.

Based on the latest guidance from NYSDEC and NYCDEP, taxis are assumed to all be in hot stabilized mode which excludes any start-up emissions. The general categories of vehicle types for specific roadways were further categorized into subcategories based on their relative fleet–wide breakdown[2].

An ambient temperature of 52.5° Fahrenheit was used for the sites in New York City. This temperature, calculated based on the latest guidance from EPA, NYSDEC, and NYCDEP, represents the average temperature measured at the Central Park meteorological station during the 10 highest 8–hour CO events measured at the East 34th Street NYSDEC air quality monitoring station during the years 2000 through 2002.

Re–entrained road dust is not expected to have a substantial impact on $PM_{2.5}$ concentrations since these particles are typically larger than 2.5 micrometers. However, the contribution of re–entrained road dust to PM_{10} concentrations, as presented in the PM_{10} SIP, is considered to be substantial, so the PM_{10} estimates include both exhaust and road dust. Road dust emission factors were calculated according to the latest procedure delineated by EPA[3].

Site Selection

The selection of air quality receptor sites followed the guidance suggested by EPA in the Revisions to the Guideline on Air Quality Models (40 CFR Part 51) and in Guideline on Air Quality Models, the EPA's Guideline for Modeling Carbon Monoxide from Roadway Intersections (EPA–454/R–92–005, 1992).

Based on the results of this screening analysis, the sites that were analyzed were the intersections of Route 9A and Vesey Street, and Route 9A and Liberty Street. These intersections include the

[2] The MOBILE6 emissions model utilizes 29 vehicle categories by size and fuel. Traffic counts and predictions are based on broader size categories, and then broken down according to the fleet–wide distribution of subcategories and fuel types (diesel, gasoline, or alternative).

[3] EPA, *Compilation of Air Pollutant Emission Factors AP–42, Fifth Edition, Volume I: Stationary Point and Area Sources*, Ch. 13.2.1, NC, http://www.epa.gov/ttn/chief/ap42/, December 2003.

locations that would experience a combination of the highest background traffic volumes and levels of service, and the highest volumes of project-induced traffic from all access routes converging near the Project Site and leaving the Project Site.

In addition, for PM modeling only, the roadways surrounding the entire site, Vesey, Church, Liberty and West Streets were modeled, adding both project contributions and additional background contributions from local roadways that would not be included in the measured background levels.

ANALYSIS OF ON-SITE CONSTRUCTION ACTIVITY

Scenarios

The analyses were performed for two scenarios, based on the alternatives being considered for the Route 9A Project. Since air pollutant emissions for the construction of the pedestrian concourse which would run under Route 9A would vary significantly depending on the choice of an at-grade or short bypass tunnel scenario for Route 9A, both scenarios were analyzed.

Emission Factors

Stationary source analysis was conducted for all construction engines predicted to be on-site, including trucks entering, exiting and idling when necessary. Diesel construction engines—excluding trucks—would be using ultra low-sulfur diesel (ULSD) fuel; where practicable, engines larger that 60 horsepower (HP) would include emissions reduction measures to reduce emissions of PM and volatile organic compounds (VOCs). These emission reductions are premised on the application of the Environmental Performance Commitments (EPCs) discussed in Chapter 3, "Construction Methods and Materials," which the PANYNJ has committed to as part of the Lower Manhattan Recovery Project's Environmental Analysis framework. These commitments have been made to lessen the severity of the potential adverse effects of construction on ambient air in lower Manhattan. For the purpose of this study, it was assumed that PM emissions from all such engines would be reduced by 40 percent—the average reduction achieved by using diesel oxidation catalysts (DOC)[1,2]. PM emissions may be further reduced in cases where diesel particle filters (DPF) would be used—85 percent reductions or higher can be achieved with this technology, and in cases where diesel engines can be replaced with electric engines connected to grid power thus eliminating those local emissions altogether. Since it is uncertain at this time what emission reduction technologies would be most efficient with each equipment type, and since DOCs reduce more VOCs, which are ozone precursors and are of regional concern, the EPCs provide the flexibility to utilize either DOC or DPF control technologies. Therefore, the minimum PM emissions reduction of DOCs was assumed for the local impact analyses.

Emission factors for all analyzed pollutants emitted from the combustion of fuel by on-site construction equipment (excluding delivery trucks/heavy vehicles) were developed using the Draft EPA NONROAD2004 Emissions Model (NONROAD)[3,1]. The model is based on source

[3] EPA, *EPA's Newest Draft Nonroad Emission Inventory Model*; www.epa.gov/otaq/nonrdmdl.htm, May 2004

inventory data accumulated for specific categories of nonroad equipment. Data provided in the output files from NONROAD were used to derive (i.e., back-calculate from regional emission estimates) the emission factors for each type of equipment that is expected to be present on-site during construction activities. Rates of emission from on-site trucks delivering or removing material were developed using the EPA MOBILE6.2 emissions model as described above. Emission rates associated with fugitive dust emissions from mobile equipment were developed using the procedures defined in EPA's AP-42[2]. Engine emissions are generally predicted to diminish over the years, as newer technologies are introduced. However, for the multi-year regional emissions inventory, VOC and PM emissions were conservatively assumed throughout construction. NO_x emissions were predicted to gradually decrease over the years as newer technologies become available.

In order to predict average concentrations for the time periods corresponding to the appropriate standards and regulations, emissions were modeled for two time periods: 24-hour and annual. These emissions were based on the construction activity predicted for each of those time scales. As described previously in Chapter 3, "Construction Methods and Materials," typical daily activity emissions were calculated on a monthly basis and averaged over the year to produce annual emission rates for each work zone; peak-day activity emissions were calculated on a monthly basis, and the values calculated for the month with the highest total emissions from all work zones were used for the 24-hour emission rates. For predictions of annual average concentrations annual average emissions were used throughout the year.

The analysis has been updated since the DEIS. The Liberty Plaza Connection is no longer assessed, and more refined information and data regarding the construction of the pedestrian concourse under Route 9A have been incorporated into the analysis based on updated construction plans from NYSDOT. This includes the elimination of the bus-way to site 26 in Battery Park City, now included as part of the WTC subgrade parking facilities (within the cumulative model). In addition to the construction under the Route 9A Short Bypass Alternative, the effect of the Route 9A At Grade Alternative on the construction of the pedestrian concourse was examined. This impacts not only the cumulative analysis, but the project-specific analysis as well since it would change the construction of the pedestrian concourse which is associated with the Preferred Alternative.

NO_x emissions include both NO and NO_2. For the microscale analyses, NO_2 is the pollutant of interest, to be compared to the NAAQS of 100 $\mu g/m^3$. Approximately 10 percent of NO_x emissions from diesel engines, such as construction equipment or trucks, are in the form of NO_2. However, NO transforms into NO_2 after it is emitted as part of the photochemical process that occurs as the pollutants travel downwind. Since the focus in the microscale analyses is on receptors immediately adjacent to the site, it is assumed that a full conversion of NO to NO_2 would not occur. The time scale for maximal conversion under urban conditions is on the order of 30 to 45 minutes (Seinfeld and Pandis, 1997).[3] After that time, maximal conversion would

[3] Seinfeld, John H., Pandis, Spyros N. 1998, Atmospheric Chemistry and Physics – From Air Pollution to Climate Change, John Wiley & Sons, New York, NY, 1997.

reach peak at approximately 58 percent, which is the regional NO_2/NO_x ratio monitored at NYSDEC stations. Since mean wind speed is 5.4 meters per second, the average detention time for the chemical reactions would be on the order of a few seconds for the nearest location, and a few minutes at most for the furthest locations downwind. At five minutes the expected conversion level is 36 percent (this would be the level at a minimum of approximately 100 meters from the source). Although much less conversion would occur by the time the pollutants reach the nearest receptors (where the highest concentrations are expected), a more conservative estimate was used for this study, assuming the average conversion rate to be 40 percent for all modeled locations.

Dispersion Modeling

Air quality impacts from construction emissions were evaluated using the Industrial Source Complex Short Term (ISC3) dispersion model developed by EPA[1]. The ISC3 model calculates pollutant concentrations from one or more sources based on hourly meteorological data, and has the capability to take into account the effect of downwash (exhaust plume affected by wakes and eddies from nearby structures). The meteorological data set consisted of the five latest years of concurrent meteorological data appropriate for the study site at LaGuardia Airport (1998–2002).

Background Concentrations

The modeling analysis directly accounts for only those pollutants emitted by local sources included in the model. Background concentrations, representing all other source contributions, must be added to the model predictions to obtain total or ambient levels at a prediction site. The highest recent monitoring data from NYCDEP monitoring stations (discussed in the next section) was used to represent background contributions from distant sources. Only the CO concentrations have been adjusted for future years to account for reduced vehicular emissions in the analysis years. Background traffic contributions from local roadways (that is traffic which is not related to the Preferred Alternative) were modeled explicitly in the same model for mobile source models, or separately for the construction site model.

RECEPTOR LOCATIONS

The emission estimates and dispersion modeling are used to determine the increase in pollutant concentration from construction activities at discrete locations in the analysis which are called receptors. Receptors were placed at locations that would have continuous public access such as residences, offices, open spaces, and in some cases sidewalks—representative locations in the vicinity of the construction activities, as well as elevated locations on all residential buildings and hotels. As shown in Figure 9–1, receptors were concentrated at locations surrounding the Project Site and in close proximity to the construction activities. As the distance increases from the construction site, the effects of construction of the Preferred Alternative on ambient air quality decreases and therefore, the greatest potential for project–related impacts would occur in the nearest group of receptors.

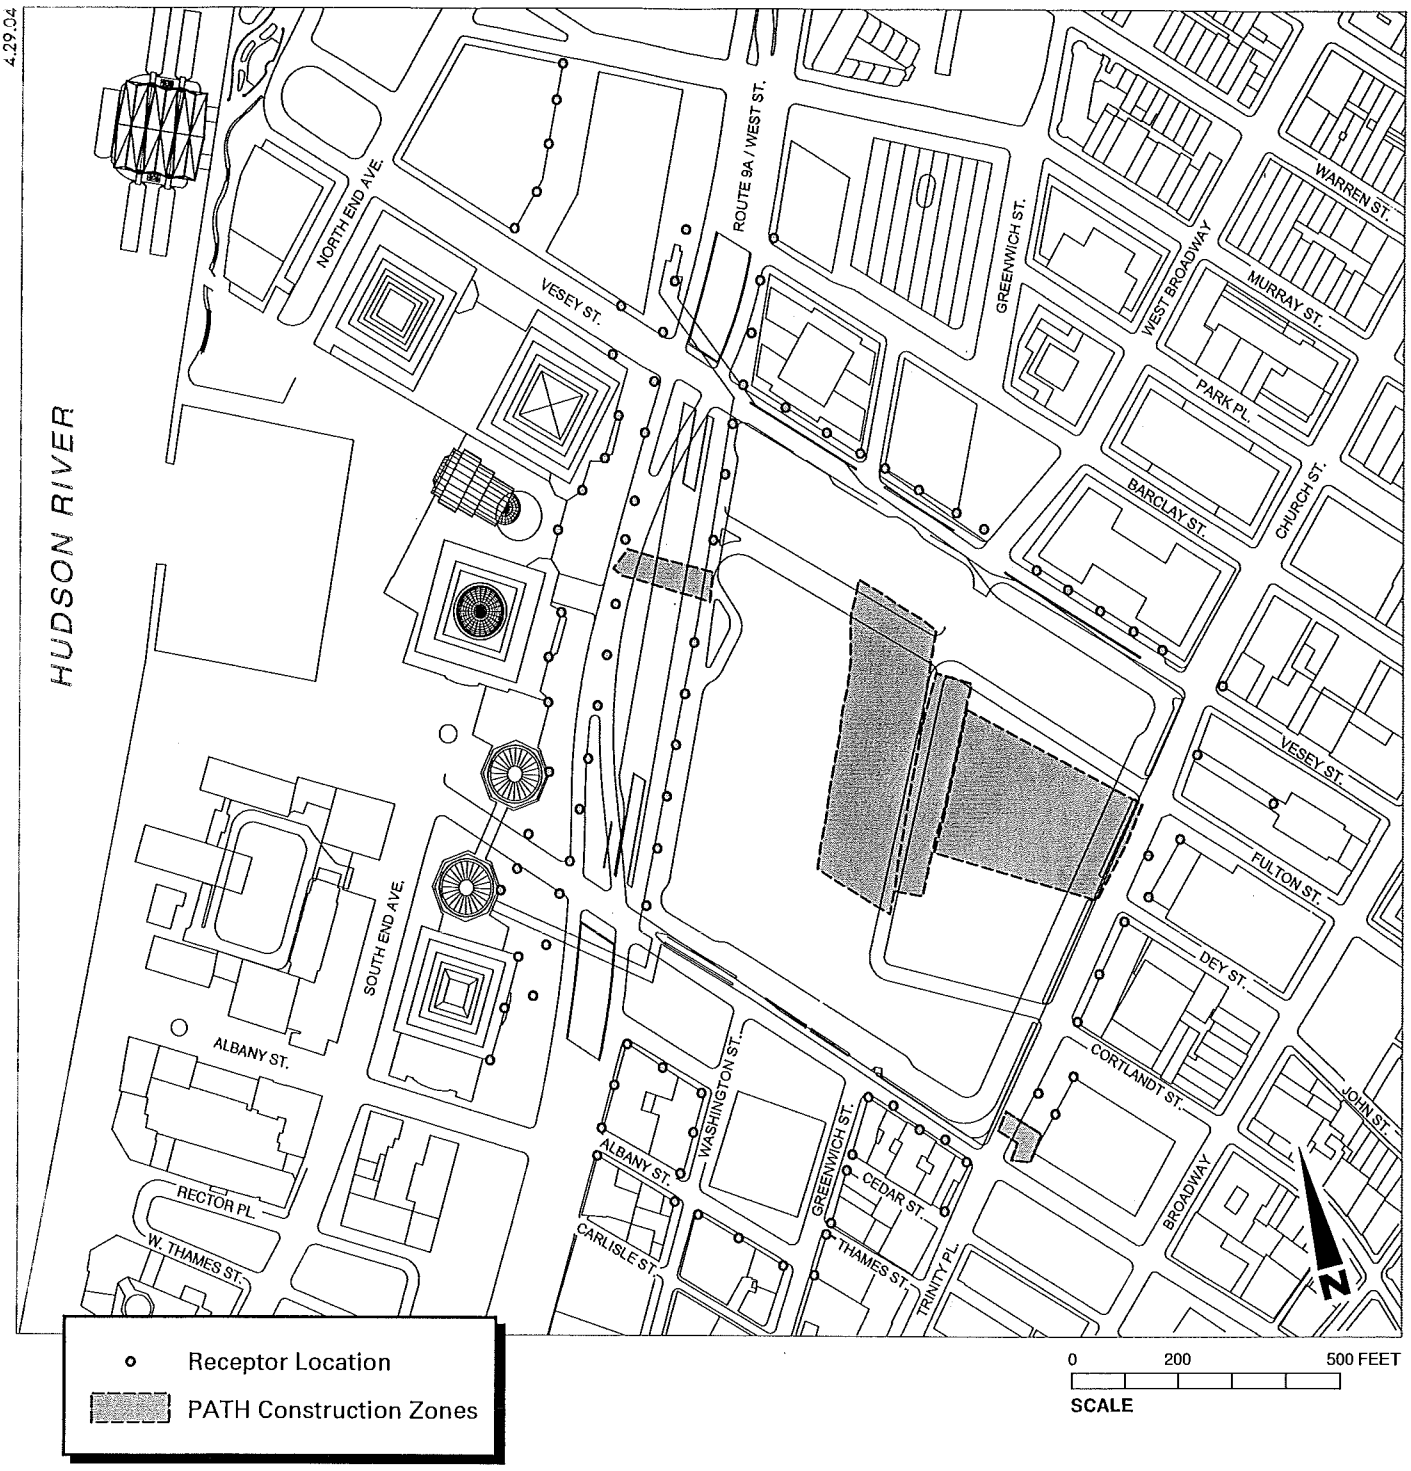

Figure 9-1

On-Site Model Source and Receptor Locations

MESOSCALE ANALYSIS OF EMISSIONS FROM CONSTRUCTION AND OPERATION OF THE PROJECT

A mesoscale (i.e., regional) analysis of air pollutants is typically performed by computing total pollutant levels ("burdens") within a project's overall study area. Pollutant burdens represent total expected quantities of pollutant emissions for a region throughout a defined time period.

CONSTRUCTION PERIOD EMISSIONS

An inventory of emissions from construction engines which would be operating on-site and from vehicles serving the construction operations of the Project Site, on an annual basis, was prepared based on the same assumptions presented above for the microscale analyses.

The inventory includes all emissions related to the construction of the Preferred Alternative. Emission factors were modeled using EPA's MOBILE6.2, AP-42 and NONROAD emissions models, as described above for the microscale analysis.

All worker, supervisor, service, utilities and fuel trips were assumed to be a round-trip distance of 18.4 miles, which is the average distance traveled for work related trips as reported by the New York Metropolitan Transportation Council (NYMTC). Concrete trucks were assumed to travel a distance of 26.2 miles—the average distances to four major concrete plants that were identified as potential suppliers. All other materials and excavated material removed from the site were assumed to travel across the George Washington Bridge, a round trip distance of 20.6 miles within the New York Metropolitan area.

A detailed description of the construction process, the engines predicted to be operating on-site and emission factors for all engines and vehicles throughout the construction years can be found in Appendix D.

Total annual emissions from construction engines were obtained by multiplying the emission factor by the hours of operation per day and the duration in days for each engine. On-road emissions were calculated by multiplying the average region-wide emission factors for each vehicle type by the distance traveled for each trip.

OPERATIONAL PERIOD EMISSIONS REDUCTION

The increment in pollutant emissions was computed for annual quantities of CO, VOCs, NO_x, and PM_{10} emitted by project-related changes in vehicular activity within the study area. Traffic reduction and the associated vehicle miles were estimated for conditions both with and without the Terminal, with the difference representing the reduction in VMT attributable to the Preferred Alternative.

Vehicular pollutant burdens were computed based on the EPA emission estimating procedures, using MOBILE6.2 (for CO, PM_{10}, VOCs, and NO_x) and the procedures described in AP-42 (for resuspended road dust). The choice and use of MOBILE6.2 is described in more detail above.

The estimate of reduced emissions due to the operation of the Terminal as compared to the No Action scenario, in which temporary service would be entirely disrupted, was computed based on annual trip reduction estimates. The annual number of vehicle trips was estimated based on travel demand factors presented in Chapter 8, "Transportation," and translated into vehicle miles based on an average travel distance of 9.2 miles for work related trips as reported by NYMTC. Assignment of the destinations and origins of the trips associated with the Preferred Alternative

was based on origin–destination information reported in the U.S. Census for the New York region.

NYSDEC has submitted detailed draft MOBILE6 regional emissions modeling results to EPA for 2007 as an update to the ozone SIP, including a breakdown of miles traveled on all roadway types and speeds by all vehicle classes. This model was used to generate NO_x and VOC emissions for all model years. The same model was revised in order to produce worst case winter CO emissions, as described in above. Meteorological conditions for the VOCs and NO_x were taken from the SIP determination, reflecting the summer ozone season.

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

PRE–SEPTEMBER 11, 2001 BASELINE CONDITIONS

The modeling analyses directly account for pollutants emitted by sources that are included in the models. However, background concentrations must be added to the concentrations predicted from these sources to obtain the total predicted ambient concentrations at any given location.

Worst–case background concentrations are represented by the highest concentrations monitored during past years at the nearest NYSDEC background monitoring stations. Stations used for background would generally be stations that are designed to monitor general population exposure and are located so as not to monitor specific local sources (i.e., stations that are not source–oriented, such as mobile source stations) but rather the impact of distant background sources. The concentrations monitored at such stations do nonetheless include a component of impacts from local sources, such as traffic, and therefore this approach results in a conservatively high estimate of total predicted concentrations.

The case of Lower Manhattan is somewhat unique in this respect. Prior to September 11, 2001, there were few, if any, monitoring stations in the immediate vicinity of the WTC site; however. in response to the terrorist attacks and the ensuing impact on air quality, New York State and Federal agencies initiated numerous air monitoring activities to better understand the ongoing impact of the disaster on air quality.

Table 9–2 provides monitoring data for both before and after the terrorist attacks. Because the post–September 11, 2001 data were collected long after the attacks, they are not influenced by the attacks themselves. These data represent existing conditions with reduced activity in Lower Manhattan, but possibly include components of ongoing reconstruction activity. Concentrations measured during both of these periods can be used as background for current conditions and future conditions in the absence of the major Lower Manhattan Recovery Projects. Modeled impacts of future activity can be added to these background concentrations as described above, to obtain the total predicted outdoor air quality. This procedure results in conservatively high concentrations because background concentrations of pollutants are decreasing over the years. The maximum concentrations presented for each pollutant and averaging period are the levels that were used as background in this study.

CHANGES IN THE AFFECTED ENVIRONMENT SINCE SEPTEMBER 11, 2001

The impact of September 11, 2001 on air quality in Lower Manhattan is related in this section. This is not intended as a comprehensive analysis, but is restricted to an overview of issues

Table 9–2
Measured Concentrations from the Nearest Air Quality Monitoring Stations

Pollutant	Station	Period	Units	2000	2001	2002	Max
CO	PS 59, 288 E. 57th Street, Manhattan	1–hour	ppm	4.1	3.7	3.2	4.1

pertinent to understanding what occurred, what may be relevant to future conditions, and to an evaluation of air quality impacts of the Preferred Alternative on the Lower Manhattan population. Data and information presented here are based on analysis of NYSDEC monitored data; the EPA study of WTC exposure[1] and oral comments on the EPA report made by the external technical peer review committee and by the public on July 14–15, 2003 and the summary report of that meeting[2], the Evaluation Report by the Office of Inspector General of the EPA on the EPA response[3]; the Natural Resources Defense Council's (NRDC) assessment[4]; and

the results of a health survey in Lower Manhattan from December 2001, performed by New York City Department of Health (NYCDOH) in collaboration with the Centers for Disease Control and Prevention (CDC)[1], as well as anecdotal information, and questions and concerns raised by members of the general public in various forums and media and can be summarized as follows:

- The massive plume of pulverized material consisted mainly of cement, glass fibers, and cellulose, but also included high concentrations of silica, calcium, sulfate, metals such as lead and zinc, and numerous other compounds. Roughly 1.5 percent of the material was respirable, i.e., smaller than 10 micrometers (μm), including approximately 0.5 percent in the $PM_{2.5}$ size range.
- During the weeks that followed September 11, 2001, concentrations of monitored air pollutants exceeded screening benchmarks, and elevated levels of contaminants were recorded within and near the WTC Site. Population exposure to these exceedances was reduced by the fact that after the event, most of the affected areas were within restricted access zones.
- By mid– to late–October, particulate matter, chromium, PCBs, and lead concentrations across Lower Manhattan had largely returned to levels typical of New York City and other U.S. urban areas.
- The large majority of outdoor air measurements of asbestos were below established benchmarks and within the range of typical background levels. A few exceedances occurred near September 11, 2001 in time and in close proximity to the WTC site. A few very high levels of asbestos were found in settled dust indoors and, of course, in the debris on the WTC site itself.
- Of the 11 VOCs evaluated, short–term exceedances of screening benchmarks were seen for acetone, benzene, 1,3–butadiene, chloromethane, ethylbenzene, and toluene. Except for benzene, exceedances for these chemicals occurred in restricted zones.

With the above in mind, and in order to minimize impacts from the simultaneous reconstruction efforts in Lower Manhattan, PANYNJ, in coordination with the other agencies involved in the reconstruction efforts, have committed to a higher standard for environmental performance in an effort to minimize or eliminate environmental impacts during the construction and the operational phases, with special attention given to air quality. The policy for substantially reducing diesel emissions during construction, for instance, will result in a large fleet of clean–technology construction equipment in service long after the Preferred Alternative is constructed; the associated long-term benefit to air pollution will be on both local and regional scales.

Regarding pollutants that are discussed in this study, particulate matter monitoring around the WTC site began on September 26, 2001. Nearly all particulate matter associated with the September 11, 2001 dust cloud was debris larger than 30 micrometers in diameter. As shown in Table 9–3, $PM_{2.5}$ measurements from newly established ground–based sampling sites around the WTC perimeter varied widely, depending on wind direction. During some days in late September and early October, 24–hr average $PM_{2.5}$ concentrations exceeded 200 $\mu g/m^3$ at locations along the WTC site perimeter. However, $PM_{2.5}$ concentrations decreased rapidly with distance from the WTC, with few $PM_{2.5}$

values exceeding EPA's Air Quality Index (AQI) level of concern at monitoring locations ranging from three to ten blocks away from the WTC. During the entire period following September 11, 2001, $PM_{2.5}$ values recorded at Lower Manhattan monitoring sites away from the WTC perimeter were not markedly different than during periods before or since the attacks.

The particulate matter concentrations monitored at the source–oriented stations, starting in 2002 (see Table 9–3), are comparable to normal concentrations in Manhattan (see Table 9–2). The PM_{10} concentrations are somewhat higher in 2002, possibly due to recovery and cleanup operations. The highest $PM_{2.5}$ concentrations in Lower Manhattan at these monitors in 2002 were actually slightly lower than the highest concentrations monitored elsewhere in Manhattan.

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

CONSTRUCTION PERIOD (2006)

FUTURE COMMON TO ALL ALTERNATIVES

In 2006, absent this project, it is likely that construction will be occurring on several major projects that could substantially affect air quality in the study area. A detailed analysis of the potential effects of these projects on ambient air quality is included in Chapter 15 "Cumulative Effects." Without the federal transportation recovery projects and the redevelopment of the WTC Memorial and Redevelopment Plan, the level of construction activity would be much less, similar to the current condition. Therefore, in the absence of the major projects, air quality in the vicinity of the Project Site would not be substantially different than current conditions.

NO ACTION ALTERNATIVE

Under the No Action Alternative, a Permanent WTC PATH Terminal would not be constructed. Therefore, air quality emissions would be the same as those described for the Future Common to All Alternatives. Predicted conditions with other major Lower Manhattan Recovery projects can be found in Chapter 15, "Cumulative Effects."

PREFERRED ALTERNATIVE

As discussed in Chapter 3, "Construction Methods and Materials," 2006 was selected as the analysis year for the microscale (local) construction impact assessment. Maximum predicted pollutant concentrations with construction of the Preferred Alternative would be lower in 2005, 2007 and 2008 than predicted for 2006 since the activity level would be much less in those years. Therefore, the predicted pollutant concentrations for 2006 have been used for impact assessment and the determination whether any additional mitigation is necessary beyond the EPCs discussed in Chapter 3. The regional (mesoscale) emissions inventory was prepared for all construction years.

Microscale (Local) On-Road Carbon Monoxide Analysis

An analysis was conducted to determine the effects of project–generated construction vehicles on ambient CO concentrations at critical intersections. The sites selected for analysis include the intersections of West Street (Route 9A) with Liberty and Vesey Streets.

Table 9–4 shows the maximum predicted 8–hour average CO concentrations with and without construction of the Preferred Alternative. As shown in the table, construction vehicles would have a negligible effect on ambient CO concentrations even at the most heavily traveled intersections in the study area. The cumulative effect from other planned construction projects along with the Preferred Alternative on CO concentrations is discussed in Chapter 15, "Cumulative Effects."

Microscale (Local) Particulate Matter and Nitrogen Dioxide Analysis

The highest predicted increase in pollutant concentrations at various locations due to construction activity of the Preferred Alternative are presented in Table 9–5. The concentrations at locations adjacent to the construction sites include contributions from both on–road sources and on–site construction activity emissions.

Table 9–4
2006 Construction Period:
Maximum Predicted 8–Hour Average CO Concentrations

Site	No Action	Preferred Alternative
Route 9A and Liberty Street	5.1	5.1
Route 9A and Vesey Street	5.5	5.5
Note: NAAQS is 9 ppm.		

Table 9–5
2006 Highest Predicted Increase in Pollutant Concentrations from Construction of the Preferred Alternative

Pollutant	Average Period	Receptor Type	Maximum Increase [$\mu g/m^3$] With Route 9A Short Bypass	Maximum Increase [$\mu g/m^3$] With Route 9A At Grade
NO_2	Annual	Highest of All Receptors	6.0	7.8
		Residential Buildings / Hotel	5.3	5.3
$PM_{2.5}$	24–hour	Highest of All Receptors	47.8*	21.7*
		Residential Buildings / Hotel	6.0*	6.8*
		Other Locations on Access Routes	0.1	0.1
	Annual	Local Highest of All Receptors	0.7*	1.0*
		Local Highest Residential / Hotel	0.5*	0.5*
		Local on Access Routes	0.01	0.01
		Neighborhood Scale	0.08	0.08
PM_{10}	24–hour	Highest of All Receptors	53.4	30.7
		Residential Buildings / Hotel	7.8	14.0
		Other Locations on Access Routes	1.0	1.0
	Annual	Highest of All Receptors	1.0	1.4
		Residential Buildings / Hotel	0.9	0.9
		Other Locations on Access Routes	0.3	0.3

Notes: Interim guidance threshold levels for $PM_{2.5}$ are 5 $\mu g/m^3$ and 0.3 $\mu g/m^3$ for 24–hour and annual increases respectively, and 0.1 $\mu g/m^3$ for neighborhood scale annual average. For determination of adverse impacts, these values are applied in the absence of specific criteria.
The NAAQS are as follows: NO_2—Annual = 100 $\mu g/m^3$; $PM_{2.5}$—24–hour = 65 $\mu g/m^3$ and Annual = 15 $\mu g/m^3$; PM_{10}—24–hour = 150 $\mu g/m^3$ and Annual = 50 $\mu g/m^3$.
* Indicates substantial adverse impact–exceeding the interim guidance thresholds.

Annual average NO_2 concentrations were predicted to increase by a maximum of 7.8 $\mu g/m^3$. This maximum was predicted near the pedestrian concourse construction zone.

In the immediate vicinity of the Project Site, the increase in PM_{10} concentrations is predicted to range up to a maximum of 53.4 $\mu g/m^3$ on a 24–hour basis, and 1.4 $\mu g/m^3$ on an annual basis due to construction of the Preferred Alternative. The predicted increase in maximum $PM_{2.5}$ concentrations in the immediate vicinity of the site would be up to a maximum of 47.8 $\mu g/m^3$ and 1.0 $\mu g/m^3$ on 24–hour average and annual average basis, respectively, and an annual average of 0.08 $\mu g/m^3$ on a neighborhood scale. The local predicted increases in $PM_{2.5}$ concentration would exceed the interim guidance threshold values. The highest annual average particulate matter concentrations, in both cases, would be near West Street by the pedestrian concourse

construction. All maximum concentrations are predicted at locations immediately adjacent to the construction site boundary. Increments would be 10 to 90 percent lower at residential locations, depending upon the pollutants and the averaging period.

To illustrate the effects of the emissions from construction on ambient air quality in the vicinity of the WTC site, isopleths (i.e. lines of equal concentration) were developed based on the predicted concentration increments. Figures 9–2 through 9–11 show the increase in annual average PM_{10}, 24–hour average PM_{10}, annual average $PM_{2.5}$, 24–hour average $PM_{2.5}$ and annual average NO_2 concentrations due to construction of the Preferred Alternative for the year 2006, under both Route 9A alternatives. These figures also indicate the location of the highest predicted increase in emissions that are detailed in Tables 9-5 and 9-6. As shown in the figures, increases in these pollutant concentrations are centered on specific construction activities, and do not vary significantly by the Route 9A alternative. Most notable are the increases centered on the West Street area (related to the construction of the pedestrian concourse). Construction activities within the bathtub or the WTC itself would have a much smaller effect on off–site concentrations due to the distance from the sources to affected areas. As shown in Figures 9–8 and 9–9, at the north–eastern edge of the site, the intersection of Church Street and Vesey Street, the 5–$\mu g/m^3$ isopleth does not extend past the northern edge of the site. This is the extent of the impacts from the elements of the Preferred Alternative's construction within the bathtub in the northern–eastern direction. The impact is somewhat more pronounced when combined with the contribution from the pedestrian concourse construction, in the north–western direction to approximately one to two blocks north of the site. The annual impact on $PM_{2.5}$, which is of higher importance due to the exceedance of the NAAQS in the existing condition, is much smaller, barely extending past the site boundary in the north and at one spot near the pedestrian concourse construction.

The above concentrations were predicted assuming only a 40 percent reduction in particulate matter based on the use of ULSD fuel in conjunction with diesel oxidation catalysts. Without these EPCs, predicted concentrations would be much higher. Additional pollution reduction estimates are discussed in Section F, "Mitigation."

The maximum total annual average NO_2 concentrations presented in Table 9–6, including background levels, predicted near the pedestrian concourse construction zone, would not exceed the NAAQS. As presented in Figures 9–10 and 9–11, slight increases in NO_2 levels may be detected in the immediate vicinity of the pedestrian concourse construction.

The total predicted PM_{10} concentrations are not predicted to exceed the NAAQS at any location during construction; therefore, construction of the Preferred Alternative alone would not result in a significant adverse impact on PM_{10} concentrations. This is largely due to strict control of both engine emissions and fugitive dust emissions.

The $PM_{2.5}$ concentrations presented are based on the highest measured 24-hour background concentration of 44 $\mu g/m^2$. It is possible that without further mitigation measures, the predicted 24-hour average $PM_{2.5}$ concentrations could exceed the NAAQS level—65 $\mu g/m^3$ at locations immediately adjacent to the site, but not at residential locations. Current annual measured background levels of $PM_{2.5}$ in New York City exceed the NAAQS of 15 $\mu g/m^3$; predicted increments are therefore compared with the threshold levels to determine the significance of impacts, as presented above.

2006 Highest Predicted Total Pollutant Concentrations During Construction of the Preferred Alternative

Pollutant	Average Period	Receptor Type	Maximum Increase [µg/m³]	
			With Route 9A Short Bypass	With Route 9A At Grade
NO_2	Annual	Highest of All Receptors	78.0	79.8
		Residential Buildings / Hotel	77.3	77.3
$PM_{2.5}$	24–hour	Highest of All Receptors	94.9*	68.9*
		Residential Buildings / Hotel	52.0	52.8
		Other Locations on Access Routes	48.2	48.2
	Annual	Highest of All Receptors	19.1**	19.2**
		Highest Residential / Hotel	18.4**	18.4**
PM_{10}	24–hour	Highest of All Receptors	115.4	92.6
		Residential Buildings / Hotel	62.8	63.7
		Other Locations on Access Routes	63.0	63.0
	Annual	Highest of All Receptors	29.6	29.9
		Residential Buildings / Hotel	26.9	26.9
		Other Locations on Access Routes	28.9	28.9

Notes: All total concentrations include calculated background contributions from local mobile sources, as well as measured regional background values as follows: NO_2—Annual average 72 µg/m³; $PM_{2.5}$—Annual average 17.1 µg/m³ (highest of 2000-2002 annual values); 24-hour average 44.0 µg/m³ (highest of the three 2nd highest 24-hour averages in 2000-2002); PM_{10}—Annual average 24 µg/m³; 24-hour average 50 µg/m³.

The NAAQS are as follows: NO_2—Annual = 100 µg/m³; $PM_{2.5}$—24–hour = 65 µg/m³ and Annual = 15 µg/m³; PM_{10}—24–hour = 150 µg/m³ and Annual = 50 µg/m³.

Cumulative and project–generated maximum concentrations may occur at a different time and/or location.

* Indicates predicted exceedance of new NAAQS without mitigation.

** $PM_{2.5}$ annual average concentrations exceed the NAAQS in the existing background condition. See Table 9-10 for comparison with incremental thresholds.

As described above, conformity requirements limit the ability of Federal agencies to assist, fund, permit, and approve transportation projects that do not conform with the applicable SIP. The New York metropolitan area has been designated by USEPA as non-attainment for $PM_{2.5}$ in December 2004, and the State of New York has until April 2008 to complete a SIP delineating how the standard will be met by 2010 (with a possible extension as late as 2015.) The SIP would include emission inventories of existing and predicted sources, including construction emission, and the planned reductions for each source. Substantial increases in $PM_{2.5}$ concentrations were predicted during construction of the Preferred Alternative, which would constitute an adverse $PM_{2.5}$ impact. However, PANYNJ's current mitigation plan (see Section E, "Mitigation") incorporates measures aimed at reducing $PM_{2.5}$ emissions to the extent practicable. In the absence of any specific guidance regarding construction emissions as it relates to transportation conformity, project-level criteria have been used to assess these potential impacts and to develop appropriate mitigation measures.

Mesoscale Emissions Analysis

The total predicted emission of PM_{10}, NO_x and VOCs by year due to the proposed construction activity, including both on-site activity and related on-road emissions, are presented in Table 9-7. Of the total predicted project-generated emissions, 50 to 61 percent of VOC, 77 to 91 percent of NOx, 40 to 61 percent of PM_{10} and 78 to 88 percent of $PM_{2.5}$ would be from on–site sources.

Table 9–7
Total Regional (Mesoscale) Direct and Indirect Emissions from Construction of the Preferred Alternative (tons per year)

Pollutant	2005	2006	2007	2008
PM_{10}	1.8	2.4	0.6	0.7
$PM_{2.5}$	1.5	1.8	0.4	0.5
NO_x	39.1	44.4	10.1	11.1
VOC	2.1	2.9	0.7	0.8
Note: PM_{10} emissions include both engine emissions and resuspended road dust.				

As compared to the projected regional emissions inventory in the New York ozone SIP for the same years—the on–road portion of the emissions would be less than 0.007 percent and 0.002 percent of the SIP mobile source NO_x and VOC emissions, respectively; the on-site portion of the emissions would be 0.06 percent and 0.004 percent of the non-road SIP NO_x and VOC emissions or less (depending on the year), respectively.

The proposed mitigation for construction emissions, aimed at reducing impacts in the immediate vicinity of the construction sites (see above) would also reduce the total region-wide emissions related to the Preferred Alternative. See Section E, "Mitigation" for details.

Air Toxins

As discussed previously, the terrorist attacks resulted in the emission of a number of hazardous air pollutants (i.e. air toxics) that raised concern regarding the public health of residents and workers in Lower Manhattan. In response to the release of these potentially hazardous materials, numerous federal, state, and local agencies initiated air quality monitoring programs in Lower Manhattan to assess the potential short- and long-term effects of these air pollutant emissions.

It should be noted that the Preferred Alternative would not introduce sources of most of the non-criteria pollutants that affected Lower Manhattan following September 11, 2001, nor would the Preferred Alternative introduce new sources of high–alkalinity PM or glass fibers. Any excavation and tunneling would not include WTC debris, which has already been removed from the site during recovery and cleanup operations. The most substantive new emission of pollutants other than criteria pollutants would be from diesel emissions from construction equipment and later from buses and trucks. Diesel exhaust includes gaseous components, such as aldehydes, benzene, 1,3–butadiene, and formaldehyde, as well as some toxics adsorbed to the surfaces of particles, such as PAHs and their derivatives—comprising less than 1 percent of the particulate diesel exhaust mass. The EPCs (see Section E, "Mitigation") of the Preferred Alternative would require strict control of diesel emissions, including emissions reduction technologies such as diesel oxidation catalysts and diesel particulate filters as well as other

measures aimed at minimizing diesel exhaust emissions during construction to the extent practicable.

OPENING YEAR (2009)

FUTURE COMMON TO ALL ALTERNATIVES

Without this project, air quality in the opening year would be similar to the no action condition in 2006. It would be a function of whether the other federal transportation recovery projects and redevelopment of the WTC are under construction. At the present time, based on current schedules, it is expected that pollutant concentrations from construction activities would peak in 2006. Therefore, contributions of air pollutant emissions from construction activities would be less in 2009 than 2006.

NO ACTION ALTERNATIVE

Under the No Action Alternative, temporary WTC PATH service would continue to operate in the opening year. Therefore, any changes in local or regional air quality emission would be attributed to other independent projects or actions.

PREFERRED ALTERNATIVE

In the opening year, major construction activity would have been completed for the Preferred Alternative. Therefore, the only potential air quality impacts from this alternative in the opening year would be beneficial, since the Preferred Alternative would generate few, if any, vehicle trips as compared to the No Action condition.

The ventilation structures would emit tunnel air during normal operations, and smoke exhaust in case of fire in the tunnels. Under normal circumstances, ventilation air would be emitted at the new locations, similar to that which was emitted in the pre-September 11, 2001 condition at ground level from the Route 9A median. The new locations would be 40 feet above grade, 28 feet higher than the previous elevation. There would be no combustion of fossil fuels, since the trains are electrically operated.

DESIGN YEAR (2025)

FUTURE COMMON TO ALL ALTERNATIVES

By the design year for the Permanent WTC PATH Terminal, construction associated with the Route 9A Project, WTC Memorial and Redevelopment Plan, Fulton Street Transit Center, and South Ferry Terminal will have been concluded for several years. Thus, certain air quality emissions anticipated during the construction period and in the opening year will be much lower in the design year. There may be some increases in vehicular traffic from residential and commercial development in Lower Manhattan. However, federal regulation will have reduced vehicle emissions, resulting in improved air quality, as compared to the pre–September 11, 2001 conditions.

NO ACTION ALTERNATIVE

Because temporary WTC PATH service would be fully disrupted by 2025 an increase in motor vehicle–related air pollutant emissions is predicted with this alternative. While motor vehicle emissions are predicted to be much lower in the design year than the opening year due to engine improvements,

the number of projected PATH riders to Lower Manhattan would be much greater. Reflecting each of these issues, Table 9–8 shows the additional air pollutants emitted in the absence of the Permanent WTC PATH Terminal.

Table 9–8
2025 Design Year No Action Alternative: Incremental Increase in Regional Pollutant Emissions without the Permanent WTC PATH Terminal (Tons/Year)

Pollutant	New Jersey	New York	Total
VOC	45.8	8.1	53.9
NO_x	39.9	7.0	46.9
PM_{10}	33.1	5.8	38.9
CO	527	93	620

Notes: Estimate for CO is high because model produces winter emissions. NO_x and VOC emissions are summer emissions, as per the ozone SIP standard procedure.

By 2025, approximately 15.7 tons of VOCs, 18.0 tons of NO_x, 1.5 tons of PM_{10}, and 236.0 tons of CO would be emitted by motor vehicles destined from New Jersey to Lower Manhattan if a Permanent Terminal is not built and if temporary PATH service is not available.

PREFERRED ALTERNATIVE

The Preferred Alternative would reduce motor vehicular traffic congestion and emissions as compared to the No Action Alternative. Therefore, the Preferred Alternative for a Permanent WTC PATH Terminal would have a far greater beneficial impact on air quality in the NYMA than the No Action Alternative.

E. MITIGATION

As described in Chapter 2, "Project Alternatives," and Chapter 3, "Construction Methods and Materials," PANYNJ has committed to EPCs to reduce the potential construction period impacts of the Preferred Alternative (see Table 9-9).

The EPCs shown in Table 9-9, were assumed as part of the construction period analysis presented above. However, the DEIS for the Permanent WTC PATH Terminal determined that addition mitigation would be needed to reduce potential construction period impacts. Following the publication of the DEIS, PANYNJ developed an enhanced mitigation plan that would substantially reduce the project's construction-period emissions.

PROJECT-SPECIFIC COMMITMENTS

In addition to measures identified in the original EPCs, PANYNJ would implement the following mitigation to further reduce project-generated emissions during the construction period.

ULTRA LOW SULFUR DIESEL FUEL (ULSD)

As described in the EPCs, PANYNJ would require that contractors use ULSD for all non-road vehicles that operate with diesel engines.

Table 9–9
Environmental Performance Commitments

Commitment	Implementation Plan
Use ultra low sulfur diesel fuel in non–road construction equipment with engine horsepower (HP) rating of 60 HP and above.	PANYNJ's construction specifications would require ULSD for all non-road, diesel-powered engines. The Authority would collect monthly samples of the ULSD fuel to verify compliance for all diesel powered engines.
Where practicable, use diesel engine retrofit technology in non–road equipment to further reduce emissions. Such technology may include Diesel Oxidation Catalyst / Diesel Particulate Filters, engine upgrades, engine replacements, or combinations of these strategies.	As part of the contract specifications, the contractor would be required to retrofit all diesel-powered equipment greater than 50 HP.
Limit unnecessary idling times on diesel powered engines to 3 minutes	As part of the contract specifications, the contractor would provide a Diesel Emission Mitigation (DEM) Plan for review and prior approval by the Resident Engineer (RE). The DEM Plan shall address the control of emissions from all engines and vehicles including those that are not equipped with emission control devices.
Locate diesel powered exhausts away from fresh air intakes.	As part of the DEM, the contractor, as determined by the RE will be required to ensure diesel powered engines vehicles are located away from fresh air intakes.
Control dust related to construction site through a Soil Erosion Sediment Control Plan that includes, among other things: a) spraying of a suppressing agent on dust pile (non–hazardous, biodegradable); b) containment of fugitive dust; c) adjustment for meteorological conditions as appropriate.	PANYNJ has developed specifications for dust suspension, materials handing, and wheel washing. The specifications require the contractor to submit a Dust Control Plan which would be implemented 24 hours per day 7 days per week.

ELECTRIFICATION

Certain construction engines which operate in a fixed position or temporarily fixed position, such as welding machines and compressors, could operate on electric power source, thus eliminating the on–site diesel exhaust source. However, there may be instances where some local generation would be needed when access to connection points is not feasible.

PANYNJ or its contractor would develop a plan, in consultation with Con Ed, as appropriate, to disperse grid power throughout the contraction zone for the Preferred Alternative. In its contract documents, PANYNJ would require all contractors and subcontractors to use electrically powered equipment for air compressors, pumps, mixing, desanding and grout plants, welding machines, and any other diesel powered equipment that can be replaced with an electrically powered version. However, this does not apply to the east-west pedestrian concourse beneath Route 9A if the concourse is built by NYSDOT, since NYSDOT has not yet finalized what level of electrification would be possible for its projects.

Given current conditions, it is expected that at lest 50 percent of the air compressors, pumps, mixing, desanding and grout plants, welding machines, and other diesel powered equipment that can be replaced with an electrically powered version would operate on electric power sources.

ADVANCED REDUCTION TECHNOLOGIES

In addition to the DOCs, which were considered as part of the original EPCs, other tailpipe emission technologies are available which can achieve reductions in PM emissions of 85 percent and as high as 98 percent, such as diesel particle filters (DPF). However, DPFs are not effective for every type of engine operation, and there may be technical difficulties in applying DPFs to some engines. The existing DPFs which have been verified by EPA or by the California Air Resources Board (CARB) as effective at substantially reducing PM emissions are mostly dependent on a high operational exhaust temperature for part of the operational cycle in order to

regenerate the filter and enable the continued operation of the engine. In some cases of construction engines that requirement is not met. DPFs with other means of regeneration exist, but would need to be tested for the specific desired applications. Also, it is possible that first application costs of cutting edge diesel reduction technology may prove to be prohibitive.

In its contract documents, PANYNJ would require the use of DPFs or other measures with equivalent PM removal efficiency for all nonroad diesel engines of 50 horsepower or greater wherever the implementation of such a device is feasible. However, there may be cases where DPFs would not be feasible for safety considerations, mechanical reasons, or where the technology would not function properly. In such cases, the constructor would submit a request for an exception for review and approval by PANYNJ prior to implementation, and in these cases, DOCs may be used. Only in cases where, for technical reasons, neither DPFs or DOCs can be used effectively, and where the operation cannot be performed by another engine or other means, would the use of diesel engines greater than 50 horsepower be allowed without tailpipe reduction measures, subject to the above described approval process.

NEWER ENGINES

The use of new construction engines would ensure that older, higher emitters are not operating on–site, and would make the operation of added control technologies easier and more efficient. For example, DPFs do not generally function with engines manufactured prior to 1994/5, since those engines did not include fuel injection. Since newer engines tend to have lower emissions to begin with, tailpipe reduction technologies would function more efficiently.

In its contract documents, PANYNJ would require the use of post-1995 fuel injection engines, which meet the Tier II engine emissions standards, as defined in Title 40, Part 89.112. Exceptions will be made only for specific engines that are not yet commercially available as Tier II, and where the task cannot be reasonably accomplished using alternative engines or means which do comply with these demands. In such cases, the contractor would submit a request for an exception for review and approval by PANYNJ prior to implementation.

DIESEL EMISSION MITIGATION (DEM) PLAN

PANYNJ would require contractors to prepare a DEM Plan that shall address the control of emissions from all engines and vehicles including those that are not equipped with emission control devices. As described in the EPCs, the DEM Plan would limit idling times on diesel powered engines to 3 minutes and would require that contractors locate diesel powered engines away from fresh air intakes.

DUST CONTROL PLAN

As described in the EPCs, PANYNJ would require contractors to submit a Dust Control Plan. Among other things, the plan would contain protocols and procedures for the spraying of dust piles, containment of fugitive dust, and appropriate adjustment measures to accommodate changes in meteorological conditions.

VERIFICATION

The effectiveness of measures to reduce construction period emissions depends on compliance. To that end, verification procedures would be implemented through construction specifications and contract documents. PANYNJ would verify mitigation and would identify opportunities to

expand its implementation as part of its ongoing oversight and auditing of the Project's construction. Furthermore, verification procedures would be implemented in accordance with decisions of the Lower Manhattan Construction Command Center, including procedures for reporting updates to the public.

OTHER EMISSIONS REDUCTION TECHNOLOGIES

PANYNJ is and will continue to investigate additional means (e.g., fuel emulsions) to reduce NO_x (NO and NO_2) emissions, but it is not yet known whether these measures would reduce the effectiveness of the above described mitigation. Therefore, specific means to further reduce NO_x have not been identified in the mitigation plan for the Preferred Alternative at this time. If this investigation results in additional means to reduce NO_x without jeopardizing the PM reduction measures and if other constraints such as technological availability are resolved, then PANYNJ would implement these additional mitigation techniques, as appropriate.

MITIGATION ANALYSIS

The above described mitigation measures would substantially reduce project-generated, construction period emissions. To quantify the effect of these measures on local pollutant concentrations, a mitigation scenario was developed and modeled using the general methodology described in Section B above.

The precise emissions reduction for each engine type is not yet known. Therefore, a conservative scenario was developed to demonstrate the effectiveness of the mitigation measures. The following assumptions were used for this analysis:

- ULSD was assumed for all non-road equipment. The use of ULSD alone was assumed to reduce PM emissions by 14 percent as compared to normal non-road diesel fuel.
- Research indicated that most diesel equipment over 150 HP can successfully employ DPFs; however, fewer pieces of equipment in the 50-150 HP range are able to do so. Because the majority of the Preferred Alternative's construction emissions would be from equipment having engines of 150 HP or greater, it was assumed that 75 percent of all engines of 50 HP or greater would employ DPFs or equivalent technology and that the remaining 25 percent would employ DOCs. On average, engines using DPFs were assumed to achieve a 90 percent reduction in PM. Those employing DOCs were assumed to achieve a 40 percent reduction in PM.
- It was assumed that all engines would be Tier II compliant; and
- It was assumed that half of all air compressors, pumps, mixing, desanding and grout plants, and welding machines used on site would operate with electric power.

Tables 9-10 and 9-11 present the results of the mitigation analysis. Table 9-10 shows the highest predicted microscale (local) increase in pollutant concentrations at various types of locations, which are depicted graphically in Figures 9-12 through 9-17. The concentrations presented in the Tables include contributions from both on–road sources and on–site construction activity emissions. The concentrations marked "Other Locations along Access Routes" represent the highest predicted impacts from on–road sources at more distant locations that would not be impacted by the construction activity on–site. The total concentrations, including background levels, are presented in Table 9-11.

Table 9–10
2006 Highest Predicted Increase in Pollutant Concentrations from Construction of the Preferred Alternative with Mitigation

Pollutant	Average Period	Receptor Type	Maximum Increase [µg/m3]	
			Route 9A Short Bypass	Route 9A At Grade
NO_2	Annual	Highest of All Receptors	5.7	7.7
		Residential Buildings / Hotel	4.4	4.4
$PM_{2.5}$	24–hour	Highest of All Receptors	16.4*	7.9*
		Residential Buildings / Hotel	2.2	2.4
		Other Locations on Access Routes	0.1	0.1
	Annual	Local Highest of All Receptors	0.2	0.3
		Local Highest Residential / Hotel	0.2	0.2
		Local on Access Routes	0.01	0.01
		Neighborhood Scale	0.04	0.04
PM_{10}	24–hour	Highest of All Receptors	21.1	16.4
		Residential Buildings / Hotel	4.1	13.3
		Other Locations on Access Routes	1.0	1.0
	Annual	Highest of All Receptors	0.6	0.7
		Residential Buildings / Hotel	0.5	0.5
		Other Locations on Access Routes	0.3	0.3

Notes:
Interim guidance threshold levels for $PM_{2.5}$ are 5 µg/m^3 and 0.3 µg/m^3 for 24–hour and annual increases, respectively, and 0.1 µg/m^3 for neighborhood scale annual average. For determination of adverse impacts, these values are applied in the absence of specific criteria.
The NAAQS are as follows: NO_2—Annual = 100 µg/m^3; $PM_{2.5}$—24–hour = 65 µg/m^3 and Annual = 15 µg/m^3; PM_{10}—24–hour = 150 µg/m^3 and Annual = 50 µg/m^3.
* Indicates substantial adverse impact–exceeding the interim guidance thresholds.

With mitigation, the maximum predicted increments are substantially lower than were shown in the construction period assessment (see Figures 9-12 through 9-21 and Table 9-10). With mitigation, maximum $PM_{2.5}$ increments would be reduced by approximately 66 percent. More importantly, neighborhood scale increments would be reduced by half to below the threshold level of 0.1 µg/m^3. As can be seen in Figures 9-16 through 9–19 (compare to base case Figures 9–6 through 9–9), the extent of increments above the interim threshold guidance levels would be reduced to a small area immediately adjacent to the site boundary, along the West Street bikeway, for 24–hour averages only. The occurrence of such high levels would depend on the coincidence of peak background levels above the 98th percentile together with peak construction activity and the extreme metrological conditions that led to the concentration predicted in the model. At a very conservative maximum, this could occur on up to six days of the peak construction year. Such an occurrence, although possible, is not likely and in any event would be rare. This would be a temporary situation, limited to a small area immediately adjacent to the Route 9A construction site and would not be expected to occur in subsequent years during which construction activity would be reduced. Construction activity will be managed by PANYNJ in this area to ensure that emissions from construction equipment and extreme meteorological conditions are prevented from occurring concurrently.

		Other Locations on Access Routes	63.0	63.0
	Annual	Highest of All Receptors	29.2	29.2
		Residential Buildings / Hotel	26.8	26.8
		Other Locations on Access Routes	28.9	28.9

Notes:

All total concentrations include calculated background contributions from local mobile sources, as well as measured regional background values as follows: NO_2—Annual average 72 µg/m^3; $PM_{2.5}$—Annual average 17.1 µg/m^3 (highest of 2000-2002 annual values); 24-hour average 44.0 µg/m^3 (highest of the three 2nd highest 24-hour averages in 2000-2002); PM_{10}—Annual average 24 µg/m^3; 24-hour average 50 µg/m^3.

The NAAQS are as follows: NO_2—Annual = 100 µg/m^3; $PM_{2.5}$—24–hour = 65 µg/m^3 and Annual = 15 µg/m^3; PM_{10}—24-hour = 150 µg/m^3 and Annual = 50 µg/m^3.

Cumulative and project–generated maximum concentrations may occur at a different time and/or location.

** $PM_{2.5}$ annual average concentrations exceed the new NAAQS in the existing background condition; however the conformity process is not yet in effect. See Table 10– for comparison with incremental thresholds.

The total concentrations from cumulative construction of the Lower Manhattan Recovery Projects, including mitigation, are presented in Chapter 15, "Cumulative Effects."

Mesoscale Emissions Analysis

Table 9-12 shows the total project-generated emission of PM_{10}, $PM_{2.5}$, NO_x and VOCs by year with mitigation. This includes both on-site activity and related on-road emissions.

As compared to the projected regional emissions inventory in the New York ozone SIP for the same years—the on-road portion of the emissions would be less than 0.007 percent and 0.002 percent of the SIP mobile source NO_x and VOC emissions, respectively; the on-site portion of the emissions would be 0.05 percent and 0.003 percent of the non-road SIP NO_x and VOC emissions or less (depending on the year), respectively.

Table 9–12
Total Emissions from Construction of the Preferred Alternative with Mitigation (tons per year)

Pollutant	2005	2006	2007	2008
PM_{10}	0.8	1.2	0.3	0.3
$PM_{2.5}$	0.5	0.7	0.2	0.2
NO_x	34.0	36.8	8.4	8.4
VOC	1.9	2.5	0.6	0.7
Note: PM_{10} emissions include both engine emissions and resuspended road dust.				

A. INTRODUCTION

This chapter assesses the potential for noise and vibration impacts from construction and operation of the proposed Permanent World Trade Center (WTC) PATH Terminal.

This chapter includes a description of impact standards and criteria, a description of existing conditions, an assessment of construction impacts, an assessment of permanent impacts once the Permanent WTC PATH Terminal is operational, and a description of potential mitigation measures. Although the analyses and corresponding mitigation measures for these two assessments contain similar language, the analyses actually assess two different types of potential impacts.

Airborne noise is what most people think of when they hear the word "noise." It is noise that travels through the air—such as the sound of traffic on a nearby roadway, or children playing in a playground. *Ground-borne noise* is the rumbling sound caused by *vibration* (or oscillatory motion). With ground-borne noise, buildings and other structures act like speakers for low-amplitude noise. As an example, ground-borne noise is the low rumbling sound that occurs within a building as a train passes beneath.

Appendix E of this Environmental Impact Statement (EIS) provides supporting information for the various analyses, including descriptive information on how noise and vibrations are perceived, and details on the assessment methodologies and conclusions.

B. METHODOLOGY

AIRBORNE NOISE

The analysis of airborne noise for the Preferred Alternative was performed using the procedures set forth in the U.S. Department of Transportation, Federal Transit Administration (FTA) guidance manual, *Transit Noise and Vibration Impact Assessment* (April 1995). This FTA document sets forth methodologies for analyzing airborne noise during construction and operation. It also provides the criteria for assessing impacts as well as suggested mitigation measures.

Airborne noise levels from construction and operation of the Permanent WTC PATH Terminal are subject to the criteria defined by the FTA. In addition, noise levels from some construction equipment are regulated by the Noise Control Act of 1972 (49 USC §§4901 et. seq.)

The FTA guidance does not present standardized impact criteria for assessing airborne, construction-period noise impacts. However, it does contain levels that if exceeded may result in adverse community reactions, which were applied in this EIS for the assessment of potential adverse impacts. Sensitivity to noise is a function of land use, time of day, and duration. Thus, the FTA criteria provides for levels by type of use, time of day, and duration. The L_{eq} noise level

represents the constant equivalent sound level of a fluctuating source, usually for a 1-hour period. The L_{dn} is a descriptor for the cumulative 24-hour, day-night noise level and accounts for greater sensitivity to noise during nighttime hours. (See Appendix E for a more detailed description of the FTA criteria.)

Table 10-1 shows the FTA impact criteria for the detailed construction noise assessment conducted in accordance with FTA methodologies. For purposes of impact assessment, an airborne noise impact would occur if noise levels during construction exceed the FTA recommended values in Table 10-1. The residential and commercial use categories are most relevant to this EIS.

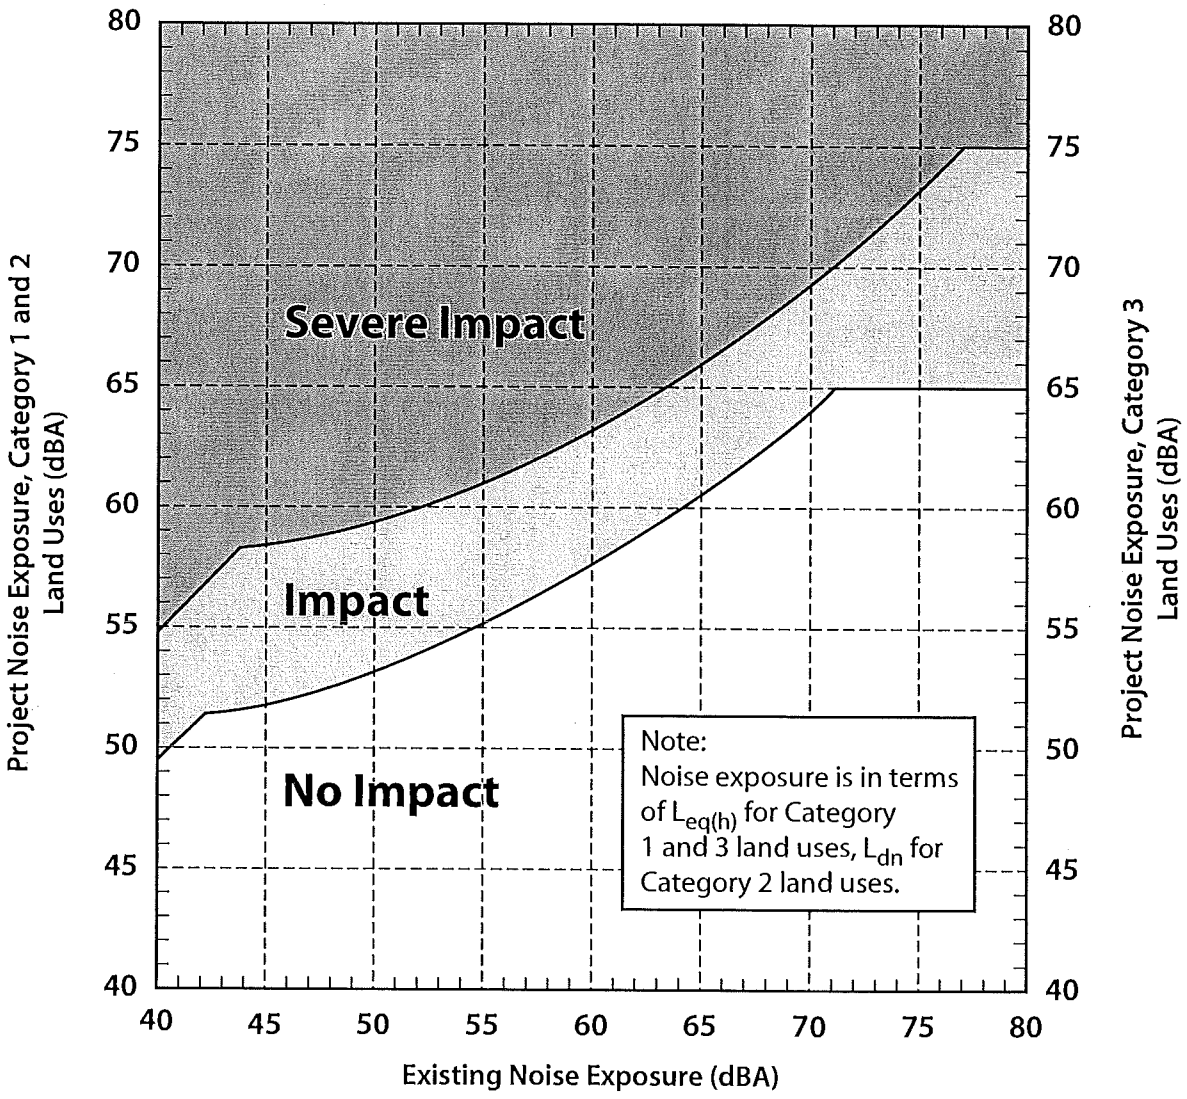
Table 10-1
FTA Impact Criteria for Detailed Assessment of Airborne Construction Noise (in dBA)

Land Use	Descriptor	Day	Night
Residential	8-hour L_{eq}	80	70
	30-day average L_{dn}	75[1]	
Commercial	8-hour L_{eq}	85	85
	30-day average $L_{eq(24)}$	80	
Industrial	8-hour L_{eq}	90	90
	30-day average $L_{eq(24)}$	85	

Note: [1] In urban areas with existing ambient L_{dn} greater than 65 dB, the impact criterion is existing ambient L_{dn} + 10 dB.

For airborne operational noise, the FTA guidance manual defines noise criteria based on the specific type of land use that would be affected, with explicit operational noise impact criteria for three land use categories. These impact criteria are based on either peak 1-hour L_{eq} or 24-hour L_{dn} values. Table 10-2 describes the land use categories defined in the FTA guidance manual, and provides noise metrics used for determining operational noise impacts. As described in Table 10-2, Categories 1 and 3—which include land uses that are noise-sensitive, but where people do not sleep—require examination using the 1-hour L_{eq} descriptor for the noisiest peak hour. Category 2, which includes residences, hospitals, and other locations where nighttime sensitivity to noise is very important, requires examination using the 24-hour L_{dn} descriptor.

As shown in Figure 10-1, the FTA impact criteria for airborne operational noise are keyed to the noise level generated by the Preferred Alternative (called "project noise exposure"). Two types of impacts—"severe impact" and "impact"—are defined for each land use category, depending on existing ambient noise levels. The difference between "severe impact" and "impact" is that a severe impact occurs with a change in noise that a substantial percentage of people find annoying, while an impact occurs when a change in noise is noticeable to most people but not necessarily sufficient to result in strong adverse reactions from the community. Equations defining the relationship between existing ambient noise levels and the "impact" and "severe impact" thresholds are presented in Appendix E, "Noise Analysis."



Source: Transit Noise and Vibration Impact Assessment, DOT-T-95-16, April 1995

Figure 10-1
FTA's Noise Impact Criteria for Transit Projects

Table 10-2
FTA's Land Use Categories and Metrics for Operational Transit Noise Impact Criteria

Land Use Category	Noise Metric (dBA)	Description of Land Use Category
1	Outdoor $L_{eq(h)}$[1]	Tracts of land where quiet is an essential element in the intended purpose. This category includes lands set aside for serenity and quiet, and such land uses as outdoor amphitheaters and concert pavilions, as well as National Historic Landmarks with substantial outdoor use.
2	Outdoor L_{dn}[2]	Residences and buildings where people normally sleep. This category includes homes, hospitals, and hotels, where a nighttime sensitivity to noise is assumed to be of utmost importance.
3	Outdoor $L_{eq(h)}$[1]	Institutional land uses with primarily daytime and evening use. This category includes schools, libraries, and churches, where it is important to avoid interference with such activities as speech, meditation, and concentration on reading material. Buildings with interior spaces where quiet is important—such as medical offices, conference rooms, recording studios, and concert halls—fall into this category. Places for meditation or study associated with cemeteries, monuments, museums. Certain historical sites, parks, and recreational facilities are also included.

Notes: [1] L_{eq} for the noisiest hour of transit-related activity during hours of noise sensitivity.
[2] L_{dn} for the 24-hour cumulative noise level.
Source: *Transit Noise and Vibration Impact Assessment*, FTA, April 1995.

For purposes of impact assessment, an airborne noise impact during operations would occur if noise levels fall in the "impact" or "severe impact" areas. For example, for Land Use Category 2 and an existing noise exposure of 60 dBA, a project-generated noise exposure of 65 dBA would result in "severe impact" while a project-generated noise exposure of 60 dBA would constitute an "impact." Similarly, for the same land use category and existing noise exposure, a project-generated noise exposure of 55 dBA would not constitute an impact.

NOISE PREDICTION METHODOLOGY

Following the procedures set forth in FTA's guidance manual, existing noise levels were first determined by field measurement. The project-generated noise levels from construction activities and the proposed PATH train operations were then calculated. Those levels were evaluated using the impact criteria discussed above to determine the Preferred Alternative's potential for adverse impacts. This methodology is discussed in more detail below.

DETERMINATION OF EXISTING NOISE LEVELS

Noise measurements were performed at receptor locations to establish existing conditions. Traffic on adjacent roadways and streets was the dominant noise source at each location.

Selection of Noise Receptors

Existing noise levels vary depending on local site conditions and the time of day. To determine the existing ambient noise levels in the area that could be affected by the construction or operation of the Preferred Alternative, specific analysis locations (referred to as "receptors") were chosen throughout the study area. A total of five receptor sites adjacent to the Project Site were chosen. These sites were selected to represent the range of land uses (e.g., residences, church, institution, offices) which would be particularly sensitive to noise increases, and would be likely to experience the greatest increases in noise from the Preferred Alternative's

construction and operation. The locations chosen as noise receptors are summarized in Table 10-3 (which also indicates each site's FTA land use category) and are shown in Figure 10-2. Potential noise and vibration impacts were also assessed at the site of the proposed WTC Memorial. However, the analysis is not based on existing noise levels since current construction activities in the WTC "bathtub" would result in an inaccurate assessment.

Table 10-3
Noise Receptor Sites and Locations

Site	Location	Land Use	FTA Land Use Category	Type of Measurement	Year of Measurement
1	Hilton Millennium Hotel (Church and Dey Streets)	Hotel	2	24-Hour	2003
2	114 Liberty Street (between Church and Greenwich Streets)	Residences and Offices	2	24-Hour	2003
3	World Financial Center (Route 9A between Vesey and Liberty Streets)	Offices	3	20-Minutes	2003
4	Barclay Street and Washington Street Intersection	Institution and offices	3	20-Minutes	2003

Note: For definition of land use categories, see Table 10-2.

Noise Monitoring

Noise monitoring was conducted at all five noise receptor sites. As shown in Table 10-3, at each site noise levels were measured for either one continuous 24-hour period or four 20-minute periods—AM, midday, PM, and nighttime. At receptor sites 1, 2, and 5, continuous 24-hour noise measurements were conducted; at receptor sites 3 and 4, 20-minute measurements were conducted. L_{dn} values for sites 3 and 4 were estimated from the 20-minute measurements as discussed below.

All measurements were performed using Type I instrumentation. Precision Sound Level Meters (SLM) were used in field measurements. The SLMs meet or exceed the requirements set forth in the ANSI S1.4-1983 Standards for Type I quality and accuracy. Acoustical calibrators were used to calibrate the SLMs before and after each measurement period. The SLMs were operated on the A-weighting network and slow-meter response as recommended by the manufacturer. Measurements were not collected if roadway pavement was wet, or if wind speed exceeded 12 miles per hour. A porous windscreen was used on each SLM during all measurement periods.

All field measurements were taken by mounting the SLMs approximately five feet above the sidewalk or ground surface at each receptor. This height is generally considered representative of the ear level of an average person. Where possible, measurement sites were located in open areas away from buildings or other potentially reflective surfaces, representative of the outdoor use area of a given receptor.

If possible, the SLMs were placed on public sidewalks in front of private properties. During measurement periods, important events and site conditions were noted, and a sketch was drawn for each receptor location showing important and permanent features of the area to aid in

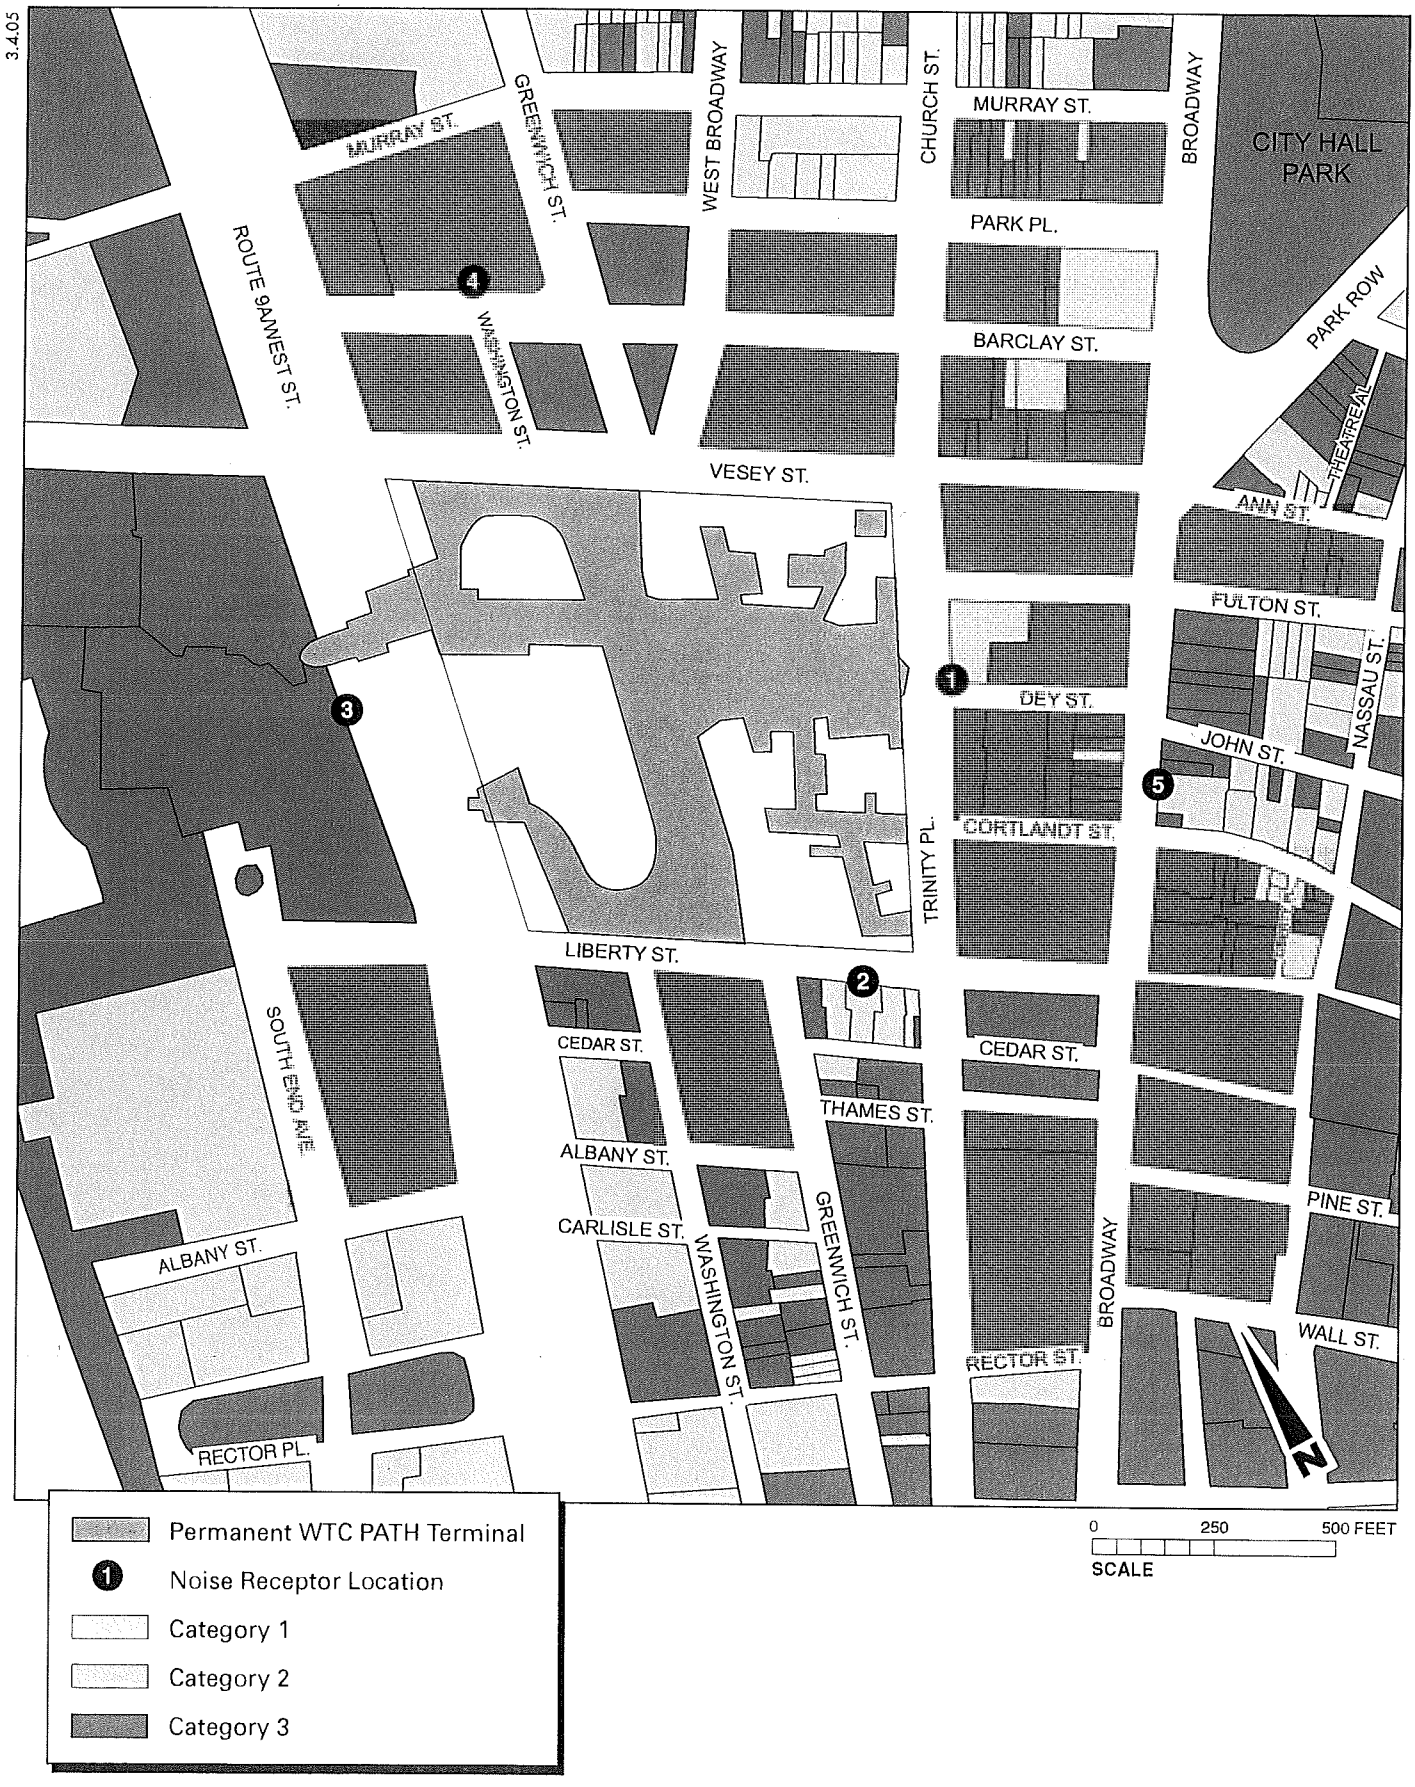

Figure 10-2

Noise Receptor Locations and FTA Land Use Categories

locating microphone positions at a later date. If an unusual noise source interrupted the measurement session, the measurement was temporarily paused until the noise source was out of range. Typical noise sources of this type include car alarms or car horns, occasional airplanes flying overhead, the roaring of motorcycles, and barking dogs.

Calculation of L_{dn} Noise Levels

L_{dn} noise levels can be calculated directly from 24-hour noise levels, but must be approximated if noise levels are not measured over a 24-hour period. The FTA guidance manual provides equations to approximate the L_{dn} noise level using either a peak, midday, and nighttime hourly L_{eq} noise level, or daytime, early nighttime, and late nighttime L_{eq} value. At receptor sites where continuous 24-hour measurement data were not available, those equations were used to calculate L_{dn} noise levels.

MODELING TO PREDICT FUTURE CONDITIONS FOR THE PROJECT ALTERNATIVES

A proportional modeling technique was used to approximate changes in noise levels from predicted changes in traffic volumes that would be independent of the Preferred Alternative. Traffic noise levels were then calculated using existing noise levels, existing traffic data, and estimated future traffic data. In general, with this technique, vehicular traffic volumes were converted into passenger car equivalent (PCE) values, for which one medium-duty truck (having a gross weight between 9,900 and 26,400 pounds) was assumed to generate the noise equivalent of 13 cars, one heavy-duty truck (having a gross weight of more than 26,400 pounds) was assumed to generate the noise equivalent of 47 cars, and each bus was assumed to generate the noise equivalent of 18 cars.

Because sound levels use a logarithmic scale, this model proportions logarithmically with traffic changes. For example, if the existing traffic volume on a street is 100 PCE with a noise level of 70 dBA, and if the future traffic volumes for No Build and Build conditions were 120 PCE and 150 PCE, respectively, then the No Build noise level would be 70.8 dBA, the Build noise level would be 71.8 dBA, and the project-generated noise level would be 64.8 dBA. This example assumes that traffic is the dominant noise source at a particular location. This assumption is true at all of the receptor locations in the vicinity of the Project Site under the baseline condition (i.e., no construction activities).

MODELING TO PREDICT IMPACTS FROM CONSTRUCTION ACTIVITIES

Noise from construction activities was estimated following the methodologies set forth in the April 1995 FTA guidance manual. The detailed noise assessment procedures were followed. The procedure is based on equations calculating noise levels from operation of each piece of construction equipment.

The combination of noise from all pieces of equipment operating during the same time period is obtained from adding the L_{eq} values for each piece of equipment. For the detailed assessment, 8-hour L_{eq} values and 30-day average L_{dn} values were calculated assuming all appropriate usage factors for the specified time periods for each element of construction as discussed in Chapter 3, "Construction Methods and Materials."

MODELING TO PREDICT IMPACTS FROM TRAIN OPERATIONS

Noise from the PATH train operations was also analyzed using the methodologies set forth in the FTA guidance manual. The analysis considered two major noise sources from PATH train

operations: noise from fixed-rail operations (i.e., noise from the PATH train operations emanating from stations, air ventilation openings, and train/subway gratings), and noise from mechanical equipment operations (i.e., substations, HVAC equipment, etc.).

The Preferred Alternative would not directly affect the operation of PATH trains (throughput or number of cars) as compared to future conditions, which were anticipated before September 11, 2001. Thus, the Preferred Alternative would not result in adverse noise impacts to existing land uses along the PATH's right-of-way. However, with the development of a memorial at the WTC site, there would be a change in land use from Category 3 to Category 1 adjacent to the proposed location of the Permanent WTC PATH Terminal. Thus a general noise assessment was performed per FTA guidance to determine operational-period noise levels and to examine potential impacts to the WTC Memorial.

Noise from rail vehicle operations would reverberate in the enclosed space of the underground tunnels and station. Reverberation effects of the tunnel and terminal would cause substantially higher noise levels resulting from source noise and reflected noise. To account for this phenomenon, noise levels were adjusted by calculating a noise level caused by the reflected portion of the fixed railway noise (which was assumed to bounce off acoustically reflective surfaces in the tunnels and terminal), and adding the noise level calculated for free-field conditions through logarithmic summation. For a conservative analysis, it was assumed that the tunnel or terminal are hard reflective surfaces with little or no sound absorption.

Based on the methods of sound propagation in enclosed spaces, i.e., the reflected effect, approximately 6dB was added to the free-field predicted noise levels and adjusted for noise receptor locations based on distance and acoustical attenuation through the terminal entrance or ventilation shaft. The analysis accounts for the fact that the Preferred Alternative's design will incorporate acoustical treatments on interior wall surfaces such as perforated metal acoustical panels containing glass fibers and spray-on mineral-based coatings. These measures would provide for 25 dBA attenuation.

VIBRATION AND GROUND-BORNE NOISE

To examine potential vibration and ground-borne impacts during construction, the FTA guidance document provides a screening procedure to project the magnitude of vibration levels to determine the potential for impacts and whether mitigation measures may be necessary. To examine potential vibration and ground-borne noise impacts during operation, the FTA guidance lays out a three-step approach: a screening procedure, a general assessment methodology, and a detailed analysis methodology. The analysis below includes a screening and general assessment. Detailed analysis is usually performed as part of the design process, when the general assessment prepared for the EIS indicates that a facility could cause potential impacts.

IMPACT CRITERIA

The vibration levels for typical human and structural responses and sources are shown in Table 10-4. Although the perceptibility threshold for ground-borne vibration is about 65 VdB, human response occurs when vibration exceeds 70 VdB.

Background vibration is usually well below the threshold of human perception, and is of concern only when the vibration affects very sensitive manufacturing or research equipment. Electron microscopes, high-resolution lithography equipment, and laser and optical equipment are typical of equipment that is highly sensitive to vibration.

Table 10-4
Typical Levels of Ground-Borne Vibration

Human/Structural Response	Velocity Level (VdB)	Typical Sources (at 50 feet)
Threshold, minor cosmetic damage fragile buildings	100	Blasting from construction projects
		Bulldozers and other heavy tracked construction equipment
Difficulty with vibration-sensitive tasks, such as reading a video screen	90	Commuter rail, upper range
Residential annoyance, infrequent events	80	Rapid transit rail, upper range
		Commuter rail, typical range
Residential annoyance, frequent events	70	Bus or truck over bump
		Rapid transit rail, typical range
Limit for vibration-sensitive equipment. Approximate threshold for human perception of vibration	60	Bus or truck, typical
	50	Typical background vibration

Source: *Transit Noise and Vibration Impact Assessment* (FTA, April 1995).

The FTA criteria for ground-borne vibration and noise from transit operations are based on the maximum levels for a single event. The criteria are shown in Table 10-5 and are used to determine if the Preferred Alternative would result in vibration and ground-borne noise impacts.

Table 10-5
Ground-Borne Vibration and Noise Impact Criteria

Land Use Vibration Category	Ground-borne Vibration Impact Criteria (VdB re 1 micro inch/second)		Ground-borne Noise Impact Criteria (dBA re 20 micro Pascals)	
	Frequent Events[1]	Infrequent Events[2]	Frequent Events[1]	Infrequent Events[2]
1	65 VdB[3]	65 VdB[3]	35 dBA[4]	43 dBA[4]
2	72 VdB	80 VdB	35 dBA	43 dBA
3	75 VdB	83 VdB	40 dBA	48 dBA

Notes:
1 "Frequent events" are defined as those with more than 70 vibration events per day. Most rapid transit projects fall into this category.
2 "Infrequent events" are defined as those with fewer than 70 vibration events per day. This category includes most commuter rail systems.
3 This criterion limit is based on levels that are acceptable for most moderately sensitive equipment such as optical microscopes. Vibration-sensitive manufacturing or research will require detailed evaluation to define the acceptable vibration levels. Ensuring lower vibration levels in a building often requires special design of the HVAC systems and stiffened floors.
4 Because the vibration-sensitive equipment in typical Category 1 buildings is not sensitive to ground-borne noise, FTA does not provide a ground-borne noise impact criterion for this category. However, Category 1 buildings for this EIS include historic structures, which may include residences. Therefore Category 2 ground-borne noise criteria are used for Category 1 as well.

Source: *Transit Noise and Vibration Impact Assessment*, FTA, April 1995, pages 8-2 through 8-3.

The limits are specified for the three land use categories defined below:

- *Vibration Land Use Category 1: High Sensitivity*—Buildings where low ambient vibration is essential for the operations within the building (e.g. vibration-sensitive research, hospitals with vibration-sensitive equipment, etc.), which may be well below levels associated with human annoyance. Although the FTA methodology does not classify historic structures in this category, this analysis does. Historic buildings are potentially sensitive to architectural damage from frequent vibration levels higher than 65 VdB. Architectural damage (e.g., cracked plaster) can adversely affect a building's historic features and character.
- *Vibration Land Use Category 2: Residential*—This category covers all residential land uses and any buildings where people sleep, such as hotels and hospitals.
- *Vibration Land Use Category 3: Institutional*—This category includes schools, churches, other institutions, and quiet offices that do not have vibration-sensitive equipment, but still have the potential for activity interference.

In terms of construction activities, the focus of vibration criteria is the levels that should not be exceeded to prevent architectural and structural damage to nearby buildings. The generally accepted criteria for avoidance of construction-related damage, which the FTA has adopted in its guidance manual, is 0.20 inches per second (approximately 100 VdB) for fragile buildings or 0.12 inches per second (approximately 95 VdB) for extremely fragile buildings.

CONSTRUCTION VIBRATION PREDICTION METHODOLOGY

The FTA guidance manual provides screening methodologies for determining where there is a potential for impact to sensitive structures from construction activities, such pile driving, demolition, drilling, excavation, or blasting. The procedure includes: 1) selecting the equipment and determining the vibratory levels at a reference distance of 25 feet; 2) determining peak particle velocity at a receptor location by adjusting for the actual distance; 3) applying the vibration damage threshold criterion discussed above; and 4) if consideration of annoyance or interference with vibration-sensitive activities is of concern, estimate the vibration level.

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

The terrorist attacks resulted in disrupted traffic flows and a general decrease in traffic volumes in the Lower Manhattan area compared with pre-September 11, 2001 conditions. This likely resulted in reduced traffic noise levels, although in some areas traffic noise levels may have remained unchanged or increased, due to the increase in traffic speeds that sometimes accompanies a decrease in volume. Construction-related cleanup and recovery activities post-September 11, 2001 added to noise levels in the area.

At receptor Sites 1, 2, and 5, a continuous 24-hour noise measurement was obtained, and at receptor Sites 3 and 4, measurements were made for four 20-minute periods during the AM peak, midday, PM peak, and at night. Measured $L_{eq(1)}$ and L_{dn} noise levels for the 24-hour continuous measurement receptor sites are shown in Table 10-6, and measured $L_{eq(1)}$ for the peak periods and calculated L_{dn} noise levels for the shorter time period measurement receptor sites are shown in Table 10-7. As shown in the tables, all of the measured noise levels are relatively high and reflect the high level of vehicular activity that takes place in the study area.

		Midday	73	
		Late Night	58	

Source: Measurements were conducted in November and December 2003.

Data gathered at parks in Lower Manhattan were used to approximate an existing noise level at the future memorial site. Because traffic flows in the area have changed since September 11, 2001, current noise levels are likely lower than values obtained before September 11, 2001 and would not be representative of the area's usual noise levels.

Measured Leq(1) noise levels at parks in Lower Manhattan are shown in Table 10-8. The lowest measured Leq(1) noise level of 65.3 dBA was selected to represent the existing noise level at the memorial site for noise analysis.

Table 10-8
Measured 20-Minute Noise Levels For Parks in Lower Manhattan (in dBA)

Battery Park City	65.3	1996

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

CONSTRUCTION PERIOD (2006)

FUTURE COMMON TO ALL ALTERNATIVES

Noise levels in the area will be highly influenced by the construction activity that is independent of the Preferred Alternative, such as the WTC Memorial and Redevelopment Plan, Route 9A Project, and the Fulton Street Transit Center. With these projects under construction, year 2006 noise levels would be substantially higher than the measured 2003 levels shown in Table 10-6 and 10-7. (Predicted construction noise levels generated by these projects are discussed in Chapter 15, "Cumulative Effects.")

NO ACTION ALTERNATIVE

Since the No Action Alternative would not result in construction of a Permanent WTC PATH Terminal, noise levels in the study area would be unchanged as compared to the Future Common to All Alternatives.

PREFERRED ALTERNATIVE

Noise

Construction activities for the Preferred Alternative would be expected to result in increased noise above current levels. These levels would vary depending on the location of construction, the equipment and construction methods employed, and the distance between the noise source and the receptor. Construction activities would occur within close proximity to sensitive land uses (e.g., residential uses); therefore the Preferred Alternative's construction has the potential to result in perceptible changes in noise levels that may result in annoyance to nearby residents. Since construction activities, in general, could take place 10 hours a day, 6 days per week, potential impacts may occur not only during the day, but also during weekend periods. Typical noise levels for construction equipment that may be used during construction of the Preferred Alternative are presented in Table 10-9.

Table 10-9
Construction Equipment Noise Emission Levels (in dBA)

Equipment	Typical Noise Level (dBA) 50 feet from source

Note: Values do not incorporate potential noise reduction measures that may be included in the Construction Noise Management Plan.
Source: *Transit Noise and Vibration Impact Assessment*, FTA, April 1995.

Noise from construction equipment is regulated by EPA noise emission standards. These federal requirements mandate that: (1) certain classifications of construction equipment and motor vehicles meet specified noise emission standards; and (2) construction materials be handled and transported in such a manner as not to create unnecessary noise. These regulations would be carefully followed. In addition, appropriate low-noise emission level equipment would be used and operational procedures implemented where feasible and practicable. Specific construction noise mitigation measures are listed on Table 10-14.

In general, the surrounding area has relatively high noise levels from existing traffic volumes, and increases in noise levels caused by delivery trucks and workers traveling to and from the construction sites would not be perceptible. However, small increases in noise levels would be expected near a few defined delivery truck routes and streets in the immediate vicinity of localized construction area. Except for the area immediately adjacent to the sites, all truck trips would be restricted to truck routes.

For receptor locations immediately adjacent to the construction area, a detailed assessment was performed to examine the potential for noise impacts during construction, rather than a general assessment. The assessment was performed using the methodology previously discussed.

Table 10-10 shows maximum predicted L_{eq} and L_{dn} noise levels in the year 2006 with construction of the Preferred Alternative, but without the implementation of noise mitigation measures. The predicted levels would exceed the recommended residential land use $L_{eq(8)}$ thresholds of 80 dBA at receptor sites 1 and 2. The predicted levels would also exceed the recommended commercial land use $L_{eq(8)}$ threshold of 85 dBA, and the 30-day L_{eq} threshold of 80 dBA at Site 3. However, the predicted levels would not exceed either the $L_{eq(8)}$ or 30-day L_{eq}/L_{dn} thresholds at Sites 4 or 5. Farther than approximately one to two blocks away, noise increases from construction of the Terminal are not expected to be substantial, due to the shielding effect of intervening buildings located between the terminal construction zone and these more distant receptors, as well as the masking effect of traffic and other ambient noise in the immediate vicinity of these receptors.

Table 10-10
2006 Construction Period Noise Levels Without Mitigation for the Preferred Alternative (in dBA)

Receptor Site	Location	Land Use Category	FTA Impact Criteria		Project-Generated Noise Levels		Impact	
			8-hour L_{eq}	30-Day *L_{dn}/ L_{eq}	8-hour L_{eq}	30-Day *L_{dn}/ L_{eq}	8-hour L_{eq}	30-Day *L_{dn}/ L_{eq}
1	Hilton Millennium Hotel	Residential	80	84	80	74	Yes	No
2	114 Liberty Street	Residential	80	81	80	74	Yes	No
3	World Financial Center/Dow Jones, on Route 9A	Commercial	85	80	88	81	Yes	Yes
4	Barclay Street and Washington Street Intersection	Commercial	85	80	69	62	No	No
5	180 Broadway	Residential	80	89	66	60	No	No

Notes: The 30-day L_{eq} is for commercial uses and the 30-day L_{dn} is for residential uses. At sites 1, 2, and 5 with high ambient noise levels (L_{dn} > 65 dB), the recommended residential use 30-day L_{dn} thresholds would be existing ambient + 10 dB (e.g. 74 dBA + 10 dBA = 84 dBA at Site 1).

Without the implementation of noise mitigation measures, construction operations would have an adverse noise impact at sensitive receptors immediately adjacent to receptor sites 1, 2, and 3.

Vibration

Construction activities associated with the Preferred Alternative would result in varying degrees of ground vibration, depending on the stage of construction, the equipment and construction methods employed, and the distance from the construction to buildings and vibration sensitive structures. Since much of the work would be within the WTC "bathtub" or near the 1 and 9 subway line, vibration levels would be perceptible off-site only for a portion of the construction period.

Table 10-11 shows typical construction equipment and vibration levels at distances varying from 5 feet to 50 feet. Depending on the distance, several of the values are above the 0.20 inches per second vibration damage threshold criterion for fragile buildings, and well above the 0.12 inches per second vibration damage threshold for extremely fragile buildings.

Table 10-11
2006 Construction Period Vibration Levels vs. Distance from Source for the Preferred Alternative (in dBA)

Equipment	Peak Particle Velocity (inches per second)					
	5 feet	10 feet	20 feet	30 feet	40 feet	50 feet
Pile driver (typical impact)	7.20	2.55	0.90	0.49	0.32	0.23
Clam shovel drop (slurry wall)	2.26	0.80	0.28	0.15	0.10	0.07
Hydromill slurry wall in soil	0.09	0.03	0.01	0.01	0.00	0.00
Hydromill slurry wall in rock	0.19	0.07	0.02	0.01	0.01	0.01
Large bulldozer	1.00	0.35	0.12	0.07	0.04	0.03
Caisson drilling	1.00	0.35	0.12	0.07	0.04	0.03
Loaded trucks	0.85	0.30	0.11	0.06	0.04	0.03
Jackhammer	0.39	0.14	0.05	0.03	0.02	0.01
Small bulldozer	0.03	0.01	0.00	0.00	0.00	0.00

To account for potential vibration impacts that may result from construction of the Preferred Alternative, all historic buildings located within 90 feet of the construction zone for the Project Site were identified (see Chapter 6, "Cultural Resources"). These buildings are: the Former East River Savings Bank; the Barclay-Vesey Building, the Beard Building, 114-118 Liberty Street, and St. Paul's Chapel and Graveyard. To avoid damage to these structures, a construction protection plan would be developed and mitigation measures would be implemented as described in Section E, "Mitigation."

FTA vibration-induced architectural damage thresholds are 0.20 inches per second peak particle velocity (PPV) for fragile buildings and 0.12 PPV for extremely fragile buildings. These thresholds would be adhered to during construction of the proposed project, for all applicable buildings.

OPENING YEAR (2009)

FUTURE COMMON TO ALL ALTERNATIVES

In the opening year, ambient noise in the vicinity of the Project Site would increase as compared to today. These increases would be attributed to vehicular traffic generated by residential and commercial development projects in Lower Manhattan as well as the independent construction of elements of the WTC Memorial and Redevelopment Plan. However, measures, such as the

Route 9A short bypass, could remove traffic from street level, which would lessen the projected increase in ambient noise.

NO ACTION ALTERNATIVE

Under the No Action Alternative, noise and vibration levels would primarily be a function of ongoing construction activities for elements of the World Trade Center Memorial and Redevelopment Plan. All other construction activities related to the Lower Manhattan Recovery Projects will have been completed, with the exception of the Permanent WTC PATH Terminal. Accordingly, construction noise and vibration levels would be substantially lower than the cumulative levels predicted for the 2006 peak construction year.

PREFERRED ALTERNATIVE

A general noise assessment as per FTA guidance was performed for the WTC Memorial site, assuming a Category 1 land use. The analysis assumes that all mechanical equipment would either be specified to have low noise levels, placed in acoustically shielded enclosures, or placed at locations where noise from equipment would not exceed 50 dBA at receptor locations. Examples of acoustical treatments for mechanical equipment include absorptive acoustical panels and enclosures, acoustical louvers, dampers, silencers, absorptive duct linings and plenums, and mufflers. As shown in Table 10-12, the predicted noise levels would be well below the impact criteria, and project-generated noise would not be expected to perceptibly increase ambient noise levels since the change in Build $L_{eq(1)}$ levels would be less than 0.5 dBA.

Table 10-12
Train Noise Impact Evaluation of the Preferred Alternative at the WTC Memorial Site

Noise Receptor Site	Land Use Category	Noise Receptor	Existing Noise Level	Allowable Project-Generated Noise Level	Actual Project-Generated Noise Level	Impact	Total (Build) Noise Level With the Proposed Project
WTC Memorial	1	L_{eq}	65.3	61.0	50.5	No	65.4
Note: For definition of land use categories, see Table 10-2.							

The ventilation structures for the Preferred Alternative would be located within the median of Route 9A. Exhaust/intake elevations would be approximately 40 feet. The fans within these ventilation structures would only be used during emergency situations and would not generate noise during normal operating conditions.

Table 10-13 shows project-generated vibration and ground-borne noise levels. Based upon the general vibration assessment results, PATH train operations would not produce vibration levels that would exceed the FTA impact criteria. PATH train operations would produce ground-borne noise levels exceeding FTA criteria for special buildings such as concert halls, TV studios, recording studios, auditoriums and theaters, which were used to represent the WTC Memorial site. However, the use of these criteria results in a conservative assessment of potential impact because, based on the information that is currently available, most of the WTC Memorial site would be open and subject to relatively high ambient noise levels (see Table 10-12). Furthermore, the WTC Memorial and the Preferred Alternative will be designed cooperatively to ensure that ground-borne noise from PATH operations would not adversely impact the WTC Memorial (see Section E, "Mitigation").

Table 10-13
Vibration and Ground-Borne Noise Impact Evaluation of the Preferred Alternative at the WTC Memorial Site

Land Use	FTA Criteria[1] Level		Predicted Project Exposure Level		Threshold Exceeded
	Vibration	Ground-borne Noise	Vibration	Ground-borne Noise	
Concert Halls, TV Studios, Recording Studios	65	25	60	40	Ground-borne noise
Auditoriums	65	30	60	40	Ground-borne noise
Theaters	72	35	60	40	Ground-borne noise

Note: [1] Vibration impact criteria for special buildings (i.e., concert halls, TV studios, recording studios, auditoriums, and theaters) are shown in Table 8-2 in the FTA Manual.

DESIGN YEAR (2025)

FUTURE COMMON TO ALL ALTERNATIVES

The WTC Memorial and Redevelopment Plan and other commercial and residential projects planned for Lower Manhattan will be completed before the design year, 2025. With these developments in place, ambient noise levels in the vicinity of the Project Site are expected to be similar to those that existed prior to September 11, 2001.

NO ACTION ALTERNATIVE

Under the No Action Alternative, noise levels in the study area would be slightly higher than with the Preferred Alternative, due to the increase in vehicular traffic (autos and buses) expected to result from a reduction in, or the elimination of, PATH service. However, this expected increase in vehicular traffic would not likely increase noise levels substantially above current conditions.

PREFERRED ALTERNATIVE

Similar to the opening year analysis, this alternative is not expected to result in impacts to the WTC Memorial, since the Preferred Alternative would incorporate design elements to reduce noise and ground-borne vibration, as necessary (see Section E, "Mitigation').

E. MITIGATION

PROJECT-SPECIFIC COMMITMENTS

CONSTRUCTION PERIOD

Noise

The implementation of the mitigation measures listed in Table 10-14 would eliminate all project-generated construction noise impacts. Table 10-15 shows maximum predicted L_{eq} and L_{dn} noise levels, with these mitigation measures in place. The mitigated levels would not exceed the $L_{eq(8)}$ or 30-day L_{eq}/L_{dn} thresholds at any of the five receptor sites.

Table 10-14
Summary of Noise Mitigation Measures

Construction Element [1]	Equipment Causing Impact	Mitigation Measures	Potential Noise Reduction (dBA)
1	Impact wrenches with noise emission level of 85 dBA at 50 ft	Use impact wrenches with noise emission level of 82 dBA at 50 ft [2]	3
	Pavement breakers	Install muffler on pavement breaker cylinder	13 [4]
3	Air-operated grout drills	Place drill inside acoustical enclosure	18 [4]

Notes: 1 See Chapter 3, "Construction," for descriptions of the construction elements.

Table 10-15
2006 Construction Period Noise Levels with Mitigation (in dBA)

Receptor Site	Location	Land Use Category	FTA Impact Criteria		Project-Generated Noise Levels		Impact	
			8-hour L_{eq}	30-Day $*L_{dn}/L_{eq}$	8-hour L_{eq}	30-Day $*L_{dn}/L_{eq}$	8-hour L_{eq}	30-Day $*L_{dn}/L_{eq}$
1	Hilton Millennium Hotel	Residential	80	84	78	72	No	No
2	114 Liberty Street	Residential	80	81	79	73	No	No
3	World Financial Center/Dow Jones, on Route 9A	Commercial	85	80	84	79	No	No
4	Barclay Street and Washington Street Intersection	Commercial	85	80	67	61	No	No
5	180 Broadway	Residential	80	89	64	58	No	No

Notes: The 30-day L_{eq} is for commercial uses and the 30-day L_{dn} is for residential uses. At sites 1, 2, and 5 with high ambient noise levels (L_{dn} > 65 dB), the recommended residential use 30-day L_{dn} thresholds would be existing ambient + 10 dB (e.g. 74 dBA + 10 dBA = 84 dBA at Site 1).

PANYNJ would verify mitigation and would identify opportunities to expand its implementation as part of its ongoing oversight and auditing of the Project's construction. This would include on-site noise monitoring during construction. Furthermore, verification procedures would be implemented in accordance with decisions of the Lower Manhattan Construction Command Center, including procedures for reporting updates to the public.

At the World Financial Center (Site 3) noise levels during the peak construction year 2006 would be above 80 dBA for the 8-hour L_{eq} at the commercial receptors affected by the Preferred Alternative. The existing windows at these receptors provide a minimum 35 dBA attenuation. Therefore, construction noise levels may increase the interior noise levels above 45 dBA, the level generally considered acceptable for indoor uses. It is expected that a combination of the measures described above, as well as additional mitigation measures to be developed as

construction methods are further refined, could reduce the Preferred Alternative's construction period impacts at these locations.

Vibration

PANYNJ and FTA have executed a Memorandum of Agreement (MOA) pursuant to Section 106 of the National Historic Preservation Act (see Appendix B-2). The MOA includes protocols for developing and implementing Construction Protection Plans (CPPs) to avoid, minimize, or mitigate the project's potential construction-period vibration impacts on the Barcley-Vesey Building, Former East River Savings Bank, the Beard Building, 114-118 Liberty Street, and St. Paul's Chapel and Graveyard.

PANYNJ and FTA, in consultation with SHPO and Section 106 consulting parties, and in coordination with LMDC, NYSDOT, and MTA/NYCT, where appropriate, shall develop a Construction Protection Plan (CPP) for the Preferred Alternative. The CPP would set forth measures for the protection and avoidance of structural and architectural damage for these historic properties. The CPP would be based on requirements in the "New York City Department of Buildings Technical Policy and Procedure Notice (PPN) #10/88" regarding procedures for the avoidance of damage to historic structures resulting from adjacent construction. The PPN defines adjacent historic structures as being contiguous or within a lateral disturbance of 90 feet from a lot under development or alteration.

The CPP would describe in detail the construction procedures of the Preferred Alternative, as well as the construction procedures associated with other projects under construction in the vicinity of each of these historic properties. It would also provide for the inspecting and reporting of existing conditions at these properties, establish protection procedures, establish a monitoring program to measure vertical and lateral movement and vibration, establish and monitor construction methods to limit vibration; and establish methods and materials to be used for any repairs. The plan shall also specify the implementation of special vibration protection measures to protect these historic properties from increased vibration levels associated with construction activities. The CPP would provide for a historical architect meeting the Secretary of Interior's Standards to supervise implementation of the CPP.

The CPP would empower the historical architect, in consultation with the Chief Engineer of PANYNJ to issue "stop work" orders to prevent any damage to historic properties, and any recommencement of work shall only be permitted at such time that the Chief Engineer and historical architect have assurance that the appropriate modifications have been made to the construction technique to assure that no damage would occur to historic properties.

OPENING AND DESIGN YEARS

As described previously, the Preferred Alternative would incorporate design measures to reduce noise from PATH trains within the WTC Memorial. Examples of these measures include acoustical treatments for mechanical equipment such as absorptive acoustical panels and enclosures, acoustical louvers, dampers, silencers, absorptive duct linings and plenums, and mufflers. The Project's architects and engineers will determine the specific measures to incorporate as the Preferred Alternative's design advances. Using these measures, PANYNJ will achieve at least 25 dBA of attenuation within the Memorial, and operational noise generated by the Preferred Alternative would be far lower than FTA's impact criteria for train noise.

As described above, the Preferred Alternative would exceed FTA's impact criteria for ground-borne noise within the Memorial. However, the impact criteria may be also exceeded by high

ambient noise levels such that ground-borne noise generated by the Terminal would not be perceptible. If it is determined that ambient noise levels within the Memorial would exceed 40 dBA, then additional mitigation measures to reduce ground-borne noise would not bee needed within the Terminal itself.

If its design guidelines specify an ambient noise level within the Memorial that is below 40 dBA, PANYNJ will explore ground-borne noise mitigation measures that would meet or exceed the desired attenuation for the Memorial. Examples of mitigation that would be explored include absorptive treatment for interior wall surfaces within the Terminal as well as the use of resilient fasteners, ballast mats, resiliently supported ties, and/or floating slabs for the PATH tracks.

ENVIRONMENTAL PERFORMANCE COMMITMENTS

As described in Chapter 2, "Project Alternatives," PANYNJ, LMDC, MTA/NYCT, and NYSDOT have developed Environmental Performance Commitments (EPCs) that would be implemented as part of their respective Lower Manhattan Recovery Projects. Table 10-16 shows these commitments as well as PANYNJ's plans for their implementation.

Table 10-16
Environmental Performance Commitments

Commitment	Implementation Plan
Where practicable, schedule individual project construction activities to avoid or minimize adverse impacts.	In accordance with Governor Pataki's November 22, 2004 Executive Order, PANYNJ will coordinate the scheduling and staging of construction activities through the Lower Manhattan Construction Command Center. The Command Center will review PANYNJ's plans in conjunction with other planned activities and will recommend schedule adjustments, as appropriate.
Coordinate construction activities with projects under construction in adjacent and nearby locations to avoid or minimize impacts.	Through the ongoing coordination efforts of the LMCCG and the Command Center, adverse noise and vibration effects on sensitive receptors will be minimized through scheduling and routing of deliveries, as well as coordination of street closures and placement of truck/equipment staging areas.
Consider condition of surrounding buildings, structures, infrastructures, and utilities where appropriate.	In accordance with the Project's executed Memorandum of Agreement, PANYNJ will perform pre-construction building conditions surveys of the potentially affected historic buildings within 90 feet of the Preferred Alternative's construction zone. These efforts would be coordinated with the other appropriate Lower Manhattan project sponsors for sites that may be affected by cumulative vibration.
Prepare contingency measures in the event established limits are exceeded.	The Permanent WTC PATH Terminal construction contractor will procure the services of a qualified acoustical firm (INCE certified or licensed Professional Engineer) to assist in the implementation of a Noise Control and Abatement Plan, which will include on-site noise monitoring during construction, and implementation of mitigation measures to ensure compliance with applicable noise exposure thresholds. Vibration monitoring specifications, and corrective actions in the event threshold levels are exceeded, will be included in the Construction Protection Plan pursuant to the Stipulations of the Project's executed MOA.

Although not required for the Preferred Alternative, additional construction noise mitigation measures may be implemented. As described in Chapter 15, "Cumulative Effects," these measures may be needed to mitigate the cumulative effects of the Lower Manhattan recovery projects at receptors affected by construction of the Preferred Alternative. To adequately address these impacts, PANYNJ, in coordination with other project sponsors, and as part of the Lower Manhattan Construction Coordination Group (LMCCG), is developing and refining a range of

construction noise and vibration mitigation measures. Specific construction noise reduction measures being explored include:

- The use of acoustic barriers and walled enclosures around certain construction activities. Noise tents/enclosures could be used around workers using jackhammers. A temporary noise barrier of 20 feet in height could be installed along the fence line/property line of the Project Site to reduce noise levels. In addition, temporary barriers, such as wood panels on top of Jersey barriers could be positioned adjacent to and moved along slurry wall and other construction operations, etc.
- The placement of construction equipment in shielded locations, such as below grade in the Project Site.
- The installation of silencers on jackhammers, air compressors, generators, light plants and cranes to reduce noise levels at specific locations (e.g., adjacent to existing residential uses).
- The use of electrically operated equipment, rather than combustion equipment, wherever possible.
- The use of soil beds, timber planking and/or exterior rubber lining on truck body and aluminum carrying case to reduce rock impact noise during truck load/unloading operations.
- The use of drive-through street-level truck enclosures for truck loading and unloading.
- The use of sheds/enclosures at concrete pump sites during concrete truck unloading, and the placement of most loading/unloading inside the bathtub and away from street level noise receptors.
- The placement of most loading/unloading inside the bathtub and away from noise receptors located at street level.
- The designation of central areas for noisy activities, such as cutting steel or wood or use of noisy equipment such as impact wrenches. When feasible, use of pre-cut, pre-fabricated, or modular construction materials that minimize need for on-site fabrication or cutting methods. ✳

A. INTRODUCTION

This chapter assesses the infrastructure and energy requirements of the Preferred Alternative. It is expected that the Preferred Alternative would require all of the utilities previously used by PATH before September 11, 2001. However, new technologies and sustainable design principals proposed with the construction and operation of the new facility would result in equal or less demand for infrastructure and energy as compared to pre-September 11, 2001 conditions.

In addition to the Terminal and its pedestrian concourses, PANYNJ would construct ancillary facilities that support PATH operations and enhance the safety and security of the WTC site. As described in Chapter 2, "Project Alternatives," the ancillary facilities include two ventilation structures within the median of Route 9A, emergency egress within the WTC site, and mechanical and communications rooms. PANYNJ would also enhance security within the Terminal with the proposed structural hardening and reinforcement of the roof of the east-west concourse. The roof of the east-west concourse would eventually become the road bed for an extended Fulton Street, as proposed in the Generic Environmental Impact Statement for the World Trade Center Memorial and Redevelopment Plan.

As described in Chapter 2, "Project Alternatives," the sponsors of the Lower Manhattan recovery projects, including PANYNJ, Lower Manhattan Development Corporation (LMDC), New York State Department of Transportation (NYSDOT), and Metropolitan Transportation Authority (MTA), have coordinated to develop environmentally friendly ("green") design and sustainability principals to reduce the demand for and use of infrastructure and resources during construction and incorporated into project design and operations.

PANYNJ has been and continues to investigate sustainable strategies for the Preferred Alternative to guide the preliminary design process. These strategies would be consistent with criteria contained in the New York City Transit Environmental Guidelines and the United States Green Building Council (USGBC) Leadership in Energy Efficiency (LEED) Guidelines 2.1 and requirements of New York State Executive Order 111.

B. METHODOLOGY

The potential impacts to infrastructure from the construction and operation of the Preferred Alternative are assessed and evaluated in this section. These construction activities and future operations are then considered with regard to existing infrastructure to determine if the Preferred Alternative would impact current utilities. The evaluation of infrastructure and energy included the following review tasks:

- The physical setting of the proposed project;
- The mapping of utilities for the World Trade Center (WTC) site and surrounding areas;
- PANYNJ reports and files;

- Regulatory agency correspondence and reports pertaining to the subject site; and
- Pertinent federal and state regulatory databases and records.

The primary goal of the PANYNJ is to achieve improved environmental and sustainable attributes in the design, construction and operation of the Preferred Alternative. To achieve this, the PANYNJ has been and continues to investigate strategies that would primarily improve energy efficiency in the Preferred Alternative. The strategies would take into consideration not just the Preferred Alternative, but also its effect on the surrounding area (i.e., regional and neighborhood issues).

The analysis involves identifying infrastructure needs for the Preferred Alternative in comparison to the pre-September 11, 2001 Terminal as well as the site existing with today's temporary PATH station. The strategies include conservation and efficiency goals for water usage, energy usage and sewage and solid waste generation. The strategies to improve the environmental and sustainable attributes in the design, construction, and operation of the Preferred Alternative would include:

- A water management plan to reduce water usage and the load on the city's water supply would be considered for the Proposed PATH Terminal utilizing the 1992 Energy Policy Act. The water management plan would set baseline requirements for the buildings' water fixtures. The goal of the water management plan would be a 30 percent reduction in the use of potable water. This reduction would be applicable towards water supply and sewage generation.
- A materials management plan would pertain to solid waste collection, recycling and disposal. While there is no quantifiable measure at this time for solid waste in conjunction with pre, post and the future PATH Terminal, it is anticipated that a reduction in solid waste would occur as a result of the implementation of the materials management plan.
- An energy management plan aimed to reduce energy consumption by twenty percent below the American Society of Heating, Refrigeration, and Air Conditioning Engineers 90.1/1999 Standard (ASHRAE). The energy management plan would incorporate the use of ENERGY STAR compliant appliances as well as a central chilling plant to achieve the reduction set.

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

PRE-SEPTEMBER 11, 2001 BASELINE CONDITIONS

The Project Site is located in an area that has substantial infrastructure needs. The description of the affected environment includes the following components: water supply, sanitary sewage and stormwater disposal, solid waste, and energy under pre-September 11, 2001 conditions.

WATER SUPPLY

Three watersheds comprise New York City's water supply system: Croton, Delaware, and Catskill. The water supply system extends as far north as the Catskill Mountains and delivers approximately 1.4 billion gallons per day (gpd) of water to its customers located in the five boroughs of New York City and Westchester County. Water from these watersheds is carried to the city by means of a complex system including, reservoirs, aqueducts, and tunnels, and is distributed throughout the city by a large network of piping.

The Croton watershed collects water from Westchester and Putnam counties and delivers it to the Jerome Park Reservoir in the Bronx. From this point the New Croton Aqueduct distributes the water to the Bronx and Manhattan via underground piping.

Water consumption in the five boroughs of New York City averages approximately 1.2 billion gpd. Average consumption in Manhattan is estimated at 420 million gallons per day (mgd); peak consumption is approximately 500 mgd. The Croton system has a lower pressure than the Delaware and Catskill systems and supplies an average of 110 mgd, primarily to domestic users in the areas of lower elevation. The Delaware and Catskill systems serve the fire hydrants and domestic uses in areas where both systems exist, and average about 310 mgd.

In 1989, the City implemented a program that sought to reduce water use by utilizing a metering program, and requiring that fixtures in existing and new buildings be of low-flow design (Local Law No. 20, 1989). Further, the City approved a water-free program where, if 70 percent of fixtures located in a facility were the type that automatically conserve water, a flat fee for water use would be initiated. These programs as well as other measures were aimed at reducing water consumption in the City.

Minimal water was used for the operation of the WTC PATH Terminal prior to September 11, 2001. Specifically, city water was used for maintenance purposes and to supply the bathroom facilities located within the PATH Terminal. Additional water was drawn from the Hudson River and used for the cooling system, which provided the WTC facility and PATH Terminal with thermal comfort.

SANITARY SEWAGE AND STORMWATER DISPOSAL

The Newton Creek Water Pollution Control Plant (NCWPCP) in Brooklyn services the Project Site and surrounding area. The NCWPCP discharges its effluent into the East River. The effluent discharged by the plant is regulated by a State Pollutant Discharge Elimination System permit, which is issued by the New York State Department of Environmental Conservation (NYSDEC). The NCWPCP has been designed to treat a monthly dry-weather flow of effluent of 310 mgd. The current 12-month average flow is 221 mgd, which is well below the design capacity. The average flow in the months prior to the events of September 11, 2001, was 218 mgd, also well below the design capacity.

The NCWPCP was built in 1967 and, at that time, no specific requirements for the levels of wastewater treatment were implemented. The NCWPCP was constructed with an aeration system that removed 60 percent of biological oxygen demand and 70 percent of total suspended solids. In 1974, the Federal Clean Water Act required a secondary wastewater treatment defined to remove 85 percent of both biological oxygen demand and total suspended solids. As of December 31, 2007, the City agreed to provide this full secondary wastewater treatment. In the interim, modifications to the wastewater treatment system at the NCWPCP are ongoing until the plant is upgraded to meet the secondary wastewater treatment facility requirements.

The Project Site and surrounding area is serviced by a combination of piping that collects stormwater runoff and sewage together (i.e., combined sewers). This system collects flows along Vesey, Church, Liberty, and Greenwich Streets and delivers them to the 78-inch diameter, South Branch Interceptor that runs along Route 9A. The interceptor carries flows to a pump station located at 14th Street and the Franklin Delano Roosevelt (FDR) Drive along the East River, and is then delivered to the NCWPCP, which is located in Brooklyn. During periods of precipitation, sewers carry both stormwater runoff and sewage to the NCWPCP. However, during times of dry

periods, only sewage is transferred to the NCWPCP. When the combined sanitary sewage and the stormwater runoff exceed the interceptor's capacities, the resultant excess is discharged to the East River without benefit of treatment.

The former PATH Terminal included both public and private bathrooms and several utility closets containing sinks. The wastewater produced in these areas was transferred to the sanitary system servicing the WTC site. Further, the former PATH Terminal did not generate any stormwater independent of the overall WTC complex or the PATH system.

SOLID WASTE

Solid waste generated in New York City is transferred to landfills located in surrounding states. Solid waste is collected from commercial and manufacturing companies through the transportation and collection services of private carters. Additionally, in 1989, the City passed a law requiring residents and businesses to separate recyclable material from other solid wastes. The law also mandates that 25 percent of the city's trash must be recycled rather than landfilled.

Solid waste produced within the former PATH Terminal resulted from trash receptacles located within the Project Site. A limited number of small businesses (e.g. coffee and news stands) located also contributed to the overall solid waste stream.

ENERGY

The New York State Conservation Construction Code was promulgated on January 1, 1979, and governs the requirements of heating, ventilation, and air conditioning systems. The Code requires that all new and recycled, public, and private buildings be designed to ensure the adequate resistance to heat loss and infiltration. Further, it provides requirements for the design of electrical, mechanical, and lighting systems to be implemented within the building.

Con Edison supplies electricity to New York City and almost all of Westchester County. Further, Con Edison supplies gas, electric, and steam energy to the WTC site. However, PATH was serviced by Public Service Energy & Gas (PSE&G). PSE&G also supplied traction power for PATH train operations with a substation located on the WTC site.

CHANGES IN THE AFFECTED ENVIRONMENT SINCE SEPTEMBER 11, 2001

The September 11, 2001 attacks resulted in the collapse of the WTC complex, including the majority of the sub-grade structures located beneath the buildings. The Project Site (PATH Terminal portion of the Project Site) currently lies at a maximum depth of approximately 65 to 70 feet below street grade. The portions of the site that would contain the tracks, platforms, mezzanine, and substation of the Preferred Alternative now house the temporary station and its support facilities. The discussion of affected environment under pre-September 11, 2001, includes information on the water supply, sanitary sewage and stormwater disposal, solid waste, and energy required to operate the previous PATH Terminal. The following section discusses the same topics with respect to the Project Site limits, including the temporary station.

WATER SUPPLY

City water service has only recently been required at the Project Site following the terrorist attacks. The temporary PATH station currently has a minimal number of sanitary facilities and an emergency fire protection system. Furthermore, the temporary station is an "open air" facility and does not require the use of heating, ventilation and air conditioning systems (HVAC).

Overall, minimal quantities of city water are required in the operation of the temporary PATH station.

SANITARY SEWAGE AND STORMWATER DISPOSAL

Currently, the Project Site is tied to the city's sanitary sewage system. Several sanitary facilities are located at the temporary PATH station on the mezzanine and substation levels. Furthermore, stormwater is collected for the entire site and pumped to the city sewer connection.

SOLID WASTE

The temporary PATH station generates minimal quantities of solid waste from operations. The waste is collected in trash and recyclable receptacles located throughout the station. Given the reduced passenger loads at the temporary PATH station, quantities of solid waste generated are less than before September 11, 2001.

ENERGY

The temporary PATH station is "open air" with no cooling system. Although energy is needed for lighting, heating systems in employee-based areas, and electrical equipment (i.e., escalators, elevators, etc.), demand is less than prior to September 11, 2001, especially with consideration to the more stringent standards and use of "green" measures set for current construction. Further, similar to conditions before September 11, 2001, traction power for train operations is provided by PSE&G with a reconstructed substation on the WTC site capable of supplying energy to the station. The PANYNJ is currently working with Con Edison to provide a connection between the WTC PATH substation and the New York City power grid. Although PSE&G can adequately supply the PATH system, a connection with Con Edison would provide for redundancy allowing for backup power in the event of a shortage or other emergency.

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

CONSTRUCTION PERIOD (2006)

FUTURE COMMON TO ALL ALTERNATIVES

In 2006, development activities for the WTC Memorial and Redevelopment Plan will occur on the WTC site, independent of the Preferred Alternative. Reconstruction of 7 WTC and its associated Con Edison substations will have been completed and may be used to power the temporary station in conjunction with the existing power supply from PSE&G.

Construction of the Route 9A short-bypass alternative would encounter several utilities located beneath the existing roadway. These include:

- A 66-inch city water line;
- A 78-inch city sewer main;
- A 48-inch city water main, and
- An 84-duct Verizon telephone utility.

These utilities would be relocated during construction. Other temporary relocation efforts may also be required for some minor utility lines located in the vicinity of the Route 9A. The relocation of utilities along Route 9A would be undertaken by the New York State Department

of Transportation (NYSDOT) as part of their reconstruction of Route 9A. However, if NYSDOT pursues the no action or at-grade alternative for the reconstruction of Route 9A, these utilities would remain in situ.

NO ACTION ALTERNATIVE

Under the No Action Alternative, temporary PATH service would continue to operate to the WTC site and there would be no construction activities with respect to Preferred Alternative. Thus, this alternative would not result in adverse impacts to infrastructure and energy issues during the construction period.

PREFERRED ALTERNATIVE

As described in Chapter 2, "Project Alternatives," the Preferred Alternative would include elements on the WTC site as well as connections beneath Route 9A to the World Financial Center. The following description of potential impacts to infrastructure and energy during the construction period addresses general issues for the construction of the entire Permanent WTC PATH Terminal and then specifically describes potential conflicts with existing infrastructure outside the limits of the WTC site.

Portions of the temporary PATH station would operate during the construction period. The design of the Preferred Alternative includes construction sequencing to ensure continuous PATH system operation at the Project Site. For the purpose of the infrastructure assessment, it has been assumed that the temporary WTC PATH station would use the utilities/infrastructure currently in place until the completion of the Preferred Alternative. Therefore, changes in infrastructure/utility requirements and systems for the Preferred Alternative are addressed below under the opening and design year. Therefore, utility usage associated with temporary station operations during the construction period would be essentially the same as today.

Various construction activities on the WTC site would be occurring in conjunction with the building of the Preferred Alternative. Overall, impacts to infrastructure for construction activities are anticipated to be minimal and would be addressed by the firms retained to perform construction activities. As described in Chapter 2, "Project Alternatives," and Chapter 3, "Construction Methods and Materials," PANYNJ would incorporate specifications into contracts to ensure that the following "green" and sustainable design strategies are met during the construction period. All sustainable strategies investigated for implementation, and as noted in this chapter exceed the expectations of the USGBC and the LEED Green Building Rating System.

- PANYNJ would provide for a Construction Stormwater Pollution Prevention Plan to conform to requirements of U.S. Environmental Protection Agency (EPA) 832/R-92-005.
- PANYNJ would investigate waste management strategies to reduce deposits to landfill. A minimum goal of 50 percent (calculated by weight) of construction, demolition, and land clearing debris would be recycled or salvaged.

Limited quantities of solid waste and sanitary sewage would be generated during construction. Stormwater is not anticipated to increase substantially as a result of construction activities and would continue to be addressed through previously described methods. Energy used to power on-site construction equipment would be provided by the contractor or through agreements with local power companies. Specifically, energy consumption would be a combination of; mobile sources, self-generating sources, and the New York City power grid.

During construction of the Route 9A concourse, groundwater and stormwater may be discharged. These waters would be treated (essentially requiring settling prior to discharge). This portion of the project may be undertaken by NYSDOT as part of their proposed Route 9A short bypass or by PANYNJ. Regardless, as described in NYSDOT's 1994 *Route 9A Reconstruction Final Environmental Impact Statement*, treated water would be cleaner than standard discharge and would therefore not adversely affect the City's sanitary systems.

As described above, there are numerous utilities beneath Route 9A in the vicinity of the WTC site. If NYSDOT moves forward with the short-bypass alternative for the reconstruction of Route 9A, then they would relocate these utilities prior to the construction of PATH's east-west connection to the Word Financial Center. If NYSDOT pursues an at-grade alternative, then the east-west connection would be built without utility relocation. However, in this scenario, PANYNJ would provide for construction protection measures to ensure that the utility lines would not be disturbed.

There may be minor utility conflicts in the vicinity of PATH's connection to the Dey Street Concourse of the Fulton Street Transit Center. These utilities would have to be either temporarily supported or relocated during construction to maintain existing service and minimize interference with the construction of the PATH Terminal. This work would be in cooperation with MTA as part of their construction of the Fulton Street Transit Center.

Overall, the review of infrastructure during the construction period has identified potential conflicts with existing utility lines at and along certain areas of the proposed concourses and pedestrian egress routes. In those instances where existing utilities occupy the same areas as permanent elements of the Preferred Alternative, they would be permanently relocated. Other conflicts would be addressed through temporary relocation and/or supporting utility lines. These actions would be undertaken to avoid disruption/interruption of service to sites within the vicinity of the Preferred Alternative. Furthermore, the relocation of any utility lines would be performed in coordination with the New York City Department of Environmental Protection, New York City Department of Transportation, NYSDOT, and the appropriate owner of that utility line (i.e., Verizon, Con Edison, etc.). Relocation efforts would be performed to not interrupt service to the surrounding area. Each utility interference would be assessed on an individual basis and adjusted as to limit the impacts to the utility and to the service it renders. Support of the utilities, if necessary, would be provided until the utility can be returned to its original position or until a relocation path is determined.

OPENING YEAR (2009)

FUTURE COMMON TO ALL ALTERNATIVES

Development activities will continue to occur on the WTC site as part of the WTC Memorial and Redevelopment plan. With respect to activities, current schedules for the project indicate that any conflicts with utilities will be addressed prior to the opening year for the Preferred Alternative.

NO ACTION ALTERNATIVE

Under the No Action Alternative, temporary PATH service would continue to operate to the WTC site and would not change regional fuel consumption and energy demand. Therefore, this alternative would not result in adverse impacts to infrastructure and energy issues in the opening year.

PREFERRED ALTERNATIVE

In the opening year, energy requirements for the Preferred Alternative would be consistent with or less than the energy requirements under the pre-September 11, 2001 conditions. Construction of the utility systems located in and servicing the WTC site would be completed. Additionally, the use of proposed "green" measures, such as the reuse of stormwater, would reduce energy demand as compared to a terminal without such measures.

Green Design

As described in Chapter 2, "Project Alternatives," PANYNJ would incorporate environmentally friendly ("green") and sustainable development principals into the design, management, and operation of the Permanent WTC PATH Terminal. These measures would reduce demand for resources and infrastructure. They would also integrate many of the Terminal's energy needs with those of the WTC site as a whole to result in a more efficient operation.

PANYNJ would prepare and implement a comprehensive resource management plan for the integrated consideration of water, materials, and energy resources with the goal of identifying, evaluating, and optimizing the use of all resources on the site. Specific measures to accommodate this plan are described below.

Water Supply

The Preferred Alternative would demand potable water for restroom facilities, human consumption, and station maintenance and cleaning. However, PANYNJ would implement strategies to reduce the Terminal's demand for potable water from the City's system. A combination of strategies would be employed to reduce demand as described below.

- During the Project's design phase, PANYNJ would prepare a Comprehensive Water Management Plan that evaluates the use of storm water, waste water, and potable water. This plan would identify measure for the onsite reclamation of wastewater. This study would investigate EPA's recommendations described in Executive Order 12123 (June 1999) and other Best Management Practices.
- PANYNJ would use Hudson River water for the cooling of the Terminal's HVAC system would negate the need to draw potable water for this purpose.
- PANYNJ would collect stormwater from surfaces of the Terminal Hall and adjacent plaza. A tank would be constructed with a capacity to accommodate a 2-year/24-hour storm. The collected water would be used for year-round flushing supply to urinals and toilets within the Terminal; year-round washing of the adjacent plaza and sidewalks; irrigation of plantings in summer months; and occasional use for façade washing.

Sanitary Sewage and Stormwater Disposal

As before September 11, 2001, only a limited number of facilities would be located within the Preferred Alternative that would generate sanitary sewage i.e. (public and private bathrooms, small utility closets with sinks). Given the similar magnitude of sanitary sewage and stormwater produced at the pre-September 11, 2001 terminal and the Preferred Alternative, no adverse impacts would occur.

However, PANYNJ would provide for the collection of stormwater from surfaces of the Terminal's Transit Hall and adjacent plaza for reuse on-site. Furthermore, PANYNJ would filter

this water to remove 80 percent of the total suspended solids. The implementation of these measures would reduce demand on the City's sewer system and treatment facilities.

Solid Waste

The Preferred Alternative is expected to generate nearly the same amount of solid waste as the temporary WTC PATH station resulting in equivalent/lesser quantities of solid waste as compared to pre-September 11, 2001, conditions. However, PANYNJ would strive to further reduce solid waste through an active, on-site recycling program. This would include a centralized space within the Terminal for the collection, sorting, and storage of recyclables as well as public recycling receptacles throughout the building.

Energy

Energy requirements for the Preferred Alternative would require a 20 percent reduction in demand, resulting in an energy demand equivalent to or less than the pre-September 11, 2001 terminal. Energy demands for the former PATH Terminal were met by PSE&G from a substation on the WTC site. The PSE&G substation, which was destroyed on September 11, 2001, has been reconstructed to serve the temporary WTC PATH station. This substation would be retained and would serve the Permanent Terminal. Redundancy with Con Edison would be provided from substations beneath 7 WTC that are currently under construction.

The energy needs of the Preferred Alternative are anticipated to be the same or less than they were prior to September 11, 2001. Technologies have become more energy efficient since the original PATH station was constructed. The new technological advances would be implemented during construction of the Preferred Alternative. Further, the Terminal would be constructed within the footprint of the original PATH station, with the addition of one extra platform. Moreover, the implementation of "green" measures including, but not limited to, energy-efficient lighting, heating, and ventilation systems, etc., would contribute to the conservation of energy and may lead to a decrease in the Project Site energy requirements. Further, an energy budget for the first year of operation and annual updates on budgeting and performance for energy resources for years thereafter would be examined for implementation. A building energy modeling system would also be considered. This system would allow for comparison of alternative strategies for energy efficiency and load reduction.

As described in the Chapter 2, "Project Alternatives," the Terminal would eventually use Hudson River water for the cooling of its heating, ventilation, and air conditioning (HVAC) systems. The reuse of the existing Hudson River water intakes and outfalls is an economical and energy-efficient method to provide cooling for the components of the Permanent WTC PATH Terminal. The intakes, pumps, outfalls, and associated pipelines that existed prior to September 11, 2001, remain largely intact. Furthermore, since river water, on average, provides lower supply temperature than other alternatives, greater energy efficiency during the heat transfer process would be achieved. Finally, river water cooling reduces the Terminal's demand on the city's water supply and electric grid as compared to conventional cooling methods.

A number of sustainable design measures would also reduce the Terminal's demand for energy. The abundant use of natural light within the Terminal would reduce daytime demand for energy. Furthermore, control and monitoring methods would regulate energy consumption and would help PANYNJ and PATH to periodically adjust operating procedures to reduce demand. These control measures include:

- A computerized, fully-integrated Building Management System (BMS) with energy and fluid flow measurement capabilities for all major energy consuming systems;
- A maintenance plan for ongoing measurement, verification, and maintenance of equipment efficiencies, and resource use;
- Programmable controls for devices;
- A permanent monitoring systems to track energy performance;
- Maintenance and operational continuity through manuals and staff education; and
- Continuous monitoring equipment for a representative sample of equipment (e.g., lighting systems, motors, drives, air distribution systems, and boilers);

PANYNJ would also purchase a portion of the Terminal's power from a supplier that uses renewable energy sources. A portion of the Terminal's mechanical area would also be set aside to accommodate future technologies that would provide for efficient, on-site, renewable energy.

WTC Site Infrastructure

As described in Chapter 6, "Cultural Resources," the project would include utility lines within the PATH right-of-way beneath the Terminal's platforms. Additional infrastructure, such as the existing PATH substation and mechanical rooms would also be located within the PATH right-of-way on the western portion of the WTC site. At elevation 242 (58 feet below sea level), all infrastructure associated with the PATH Terminal would be within PATH's right-of-way. At higher elevations (Elevation 264 or above), it may be necessary to construct utility lines for the coordination of infrastructure between PATH and the WTC Memorial and Redevelopment Plan. Such work would be implemented in coordination with LMDC, pursuant to the stipulations of the project's executed Memorandum of Agreement (see Appendix B).

While maintaining the ability to advance the Permanent WTC PATH Terminal's construction independent of the WTC Memorial and Redevelopment Plan, PANYNJ continues to explore opportunities for joint infrastructure to serve both the PATH Terminal and elements of the WTC Memorial and Redevelopment Plan. Examples of these opportunities include a central chiller plant for the WTC site; river water cooling; centralized recycling and waste collection; centralized security checkpoints, and a stormwater collection and distribution system. Joint infrastructure would reduce infrastructure demand through efficiencies and economies of scale that would not be achieved on a project-by-project basis. Therefore, the use of joint infrastructure in conjunction with the WTC Memorial and Redevelopment Plan would further reduce the infrastructure and energy needs of the Terminal as compared to a wholly, stand-alone facility.

DESIGN YEAR (2025)

FUTURE COMMON TO ALL ALTERNATIVES

All development efforts on the WTC site would be completed before the design year. Furthermore, any utility conflicts, such as relocation or shoring, will be resolved prior to the opening year. Although demand for infrastructure and energy will be greater following the full reoccupation of the site than it is today, advances in building construction and the sustainable design measures that will be implemented as part of the WTC Memorial and Redevelopment Plan are expected to reduce levels of consumption as compared to pre-September 11, 2001 conditions.

NO ACTION ALTERNATIVE

The No Action Alternative may result in the full disruption of PATH service to Lower Manhattan by the design year. As described in Chapter 8, Section B, "Vehicular Traffic and Parking," the absence of PATH service to Lower Manhattan would result in the diversion of PATH riders to private automobiles, buses, and vans, resulting in approximately 1,200 new vehicle trips in the AM peak hour. There may also be an increase in ferry ridership, which would necessitate additional operation of vessels between New Jersey and New York. These vehicles would require fuel and would therefore expend energy. Because these diverted trips would not be anticipated if PATH were operational, they would use energy sources that would not be needed for the Preferred Alternative.

PREFERRED ALTERNATIVE

Because the Terminal would be fully operational in both the opening and design years, its demand for infrastructure and energy would be quite similar.

Water Supply

As in the opening year, the Preferred Alternative would demand potable water for restroom facilities, drinking, and station maintenance and cleaning. Thus, combined with implementation of the previously discussed "green" measures would likely result in a reduced demand for water supply from the City in the design year as compared to pre-September 11, 2001 conditions.

Sanitary Sewage and Stormwater Disposal

Minimal changes to sanitary sewage generation or disposal method are anticipated in the design year. However, a complete system of storm drainage would be provided for surrounding plaza and roof areas. Areas located below the levels of the city sewers would drain to sump pits, which would be pumped to the storm sewers leaving the site. Drainage from the roof areas and waste steam condensate would be piped to stormwater retention tanks. All water would be filtered and pumped via non-potable piping for reuse at the site (water closets and urinals). Given the reuse of stormwater at the site through the previously described means, a reduction in stormwater disposal is anticipated for the city sewer system servicing the area in the design year. Thus, no impacts are anticipated with regard to sanitary sewage and stormwater disposal in the design year.

Solid Waste

An increase in ridership is anticipated between the opening year and the design year. As such, the quantities of solid waste expected to be generated from the resultant ridership would slightly increase. However, the implementation of "green" measures would reduce the overall amount of solid waste produced and removed from the Terminal. Therefore, this alternative would not result in impacts from solid waste generation in the design year.

Energy

Energy loads, including those needed for traction power, are expected to be similar to those in the opening year and that which was demanded prior to September 11, 2001. Thus, with the implementation of "green" measures, such as energy efficient lighting and renewable energy, and the expectations of the Con Edison and PSE&G substations to supply energy at or above previous quantities, the fully operating Permanent WTC PATH Terminal in the design year would not adversely impact energy supply in the surrounding area.

E. MITIGATION

No additional mitigation would be required for infrastructure and energy for the elements of the Preferred Alternative due to the sustainable strategies that would be implemented in the design, construction, and operation of the Preferred Alternative. These strategies would result in a reduction of water usage of the City's water supply, solid waste production, sanitary sewage production, and energy consumption. ✳

A. INTRODUCTION

As previously described, the Project Site is located in an area that has a long development history. The Project Site has undergone various phases of development, including a mixture of residential and commercial (pre-1950s), increased commercial intermixed with limited residential and light industrial (1950–1970s) and, ultimately, primarily commercial, combined commercial/residential and community uses (post-1970s to current).

Given the former uses and sustained urban history of Lower Manhattan, the potential exists that contaminated (or hazardous) materials may have been used in connection with development and/or facility operations at and in the vicinity of the Project Site. Furthermore, based on the age of the structures, building materials on the site are likely to have included asbestos (insulation, roofing, etc.) and/or lead (paint). The presence of contaminated materials is not uncommon or unexpected at urban sites and is generally regarded as a function of prior usage. The presence of any contaminated materials would be addressed prior to or in conjunction with the development of a Permanent World Trade Center (WTC) PATH Terminal and efforts would be undertaken by conducting appropriate engineering and construction practices to eliminate worker and public exposure to such materials. Further, the potential presence of contaminated materials at the Project Site has been virtually eliminated as a result of the rescue and recovery effort undertaken subsequent to the terrorist attacks of September 11, 2001.

This chapter documents the consideration and evaluation of contaminated materials impacts for the Project Alternatives including an assessment of potential risks to public health, safety, and the environment.

B. METHODOLOGY

This chapter describes the affected environment (i.e., baseline environmental conditions) of the WTC site and areas that would be affected by the proposed off-site pedestrian connections as related to contaminated materials. This chapter then provides an assessment/evaluation of impacts associated with potential or identified contamination issues, particularly with regard to construction. The objective of the assessment is to identify any contaminants, which would be disturbed during construction or facility operation, and to fully assess any potential risks to human health, safety, and the environment. As necessary, this chapter identifies measures that would be undertaken to eliminate or mitigate the potential contaminated materials impacts.

Information gained through the performance of the following tasks was relied upon in the preparation of the contaminated materials assessment:

- Review of the physical setting of the proposed project;

- Review of the historical uses within the Project Site limits, the WTC site, and at surrounding areas using aerial photographs, Sanborn Fire Insurance Maps, United States Geological Survey (USGS) topographic maps, and historical reports;
- Reconnaissance of the Project Site, WTC site, and surrounding areas;
- Review of regulatory agency correspondence and reports pertaining to the post-September 11, 2001 cleanup activities;
- Review of federal and state regulatory databases and records; and,
- Review of the New York City Building's Department Archives (file access provided on November 21, 2003) including mapping and documentation of Battery Park City development and maps presenting geologic cross sections of Route 9A and intersecting east-to-west streets.

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

PRE-SEPTEMBER 11, 2001 BASELINE CONDITIONS

The Project Site is located in an area that has a long history of various development and transportation uses. The following description of the affected environment includes its geology and landform, historical uses, and environmental conditions with respect to potential contaminants prior to September 11, 2001.

GEOLOGY AND LANDFORM

Regional Geology

The Project Site and surrounding area are located within the Manhattan Prong of the New England Upland Physiographic Province of the Northeastern United States. This vast province includes all of New England as well as parts of New York, New Jersey, and Pennsylvania. The Manhattan Prong is categorized as igneous and primarily metamorphosed bedrock. The early development of this province occurred during the early Paleozoic Era (~550 million years ago) when sediments from structural ridges and volcanic islands eroded into the Appalachian eugeosyncline. As eroded sediment accumulated in this trough-like depression, the overlying weight caused the lower most sediment to compress, thus allowing more sediment to accumulate. This process occurred repeatedly and allowed for enormous volumes of sediment to accumulate. The compression forces generated by the weight of this overlying material eventually resulted in the metamorphism of the deepest sediments. Further faulting and deformation occurred during the late Taconic Orogeny or mountain building episode of the Ordovician-early Silurian Periods (450-460 million years ago). Overlying layers of rock and sediment were eroded as the region was slowly uplifted, exposing the highly fractured metamorphic rocks below. These metamorphic rocks form the present day island of Manhattan.

Bedrock Geology

The total thickness of bedrock underlying the Project Site and surrounding area is estimated to be approximately 1,600 feet. These formations are interpreted as large northeast/southwest-oriented synclines and anticlines. The synclines are composed of the harder, more erosion-resistant Manhattan schist and Fordham gneiss while the valleys are subsequently composed of less resistant Inwood marble. The Manhattan schist (Lower Cambrian), which directly underlies

the Project Site, is predominantly well-foliated sillimanite-muscovite-biotite-kyanite schist with inter-bedded black gneiss and amphibolite. At its thickest point, this formation is approximately 200 to 750 feet thick. Throughout the Manhattan schist are zones of non-foliated granitic igneous rocks composed of quartz, feldspar, muscovite and biotite-mica. Extending into the southeast corner of the subject site is a zone of igneous quartzite. This zone is believed to have formed in place rather than being an intrusive feature. The Waloomsac Formation (Middle Ordovician) underlies the Manhattan schist. This formation is approximately 250 to 750 feet in thickness and is composed of primarily plagioclase-garnet-muscovite-biotite-quartz schist. The Waloomsac Formation lays uncomformably above the Inwood marble (Ordovician to lower Cambrian). The Inwood marble is composed primarily of un-foliated dolomitic marble and ranges in thickness from 600 to 700 feet. The Fordham gneiss (Middle Proterozoic) underlies the abovementioned formations and consists primarily of well-foliated quartz and orthoclase feldspar.

Soil Characteristics

Soils overlying the bedrock at the surrounding area consist generally of glacial till, organic silts associated with shallow marine environments, and non-native fill material. The Laurentide Ice Sheet covered all of New York State during the Wisconsinan Stage and was completely retreated from New York approximately 10,000 years ago. As the ice sheet retreated, glacial till was deposited throughout New York, including Manhattan. Layers of gravel, sand, and silt are present on site and become thicker to the west. These layers create a lateral burden on the slurry wall that presently exists on site. Above the glacial till lays silts and clays associated with shallow marine environments. Some time after 1609 but prior to 1900, the eastern bank of the Hudson River was located where Greenwich Street is located today. Thus, the present location of the Project Site was historically "under water" during the time of deposition. Fill material was used to expand the western edge of Manhattan over 500 feet, including the Project Site and the surrounding WTC site. Fill material used in the surrounding area is reported to have consisted of a wide variety of material including dredged river sediment. During the development of the WTC complex much of the soil including the fill material was removed from within the limits currently occupied by the temporary WTC PATH station as part of the construction of the subsurface elements. Prior to the construction of the WTC complex, soil at the Project Site is reported to have consisted of 5 to 40 feet of glacial outwash and till covered by 10 to 30 feet of organic marine sediment with 20 to 35 feet of fill material. Soil conditions on other portions of the WTC site (i.e., the eastern portion) are reported to be similar to that which was formerly located at the Project Site with respect to thickness and distribution. At this time, the PATH Terminal portion of the Project Site is devoid of overburden soil as a result of the removal effort performed subsequent to September 11, 2001.

Bedrock exists at 55 to 75 feet below surface grade at the Project Site and at 65–80 feet below surface grade at the remaining portion of the WTC site. Further information on the affected environment subsequent to September 11, 2001 is provided below. Conditions of the surrounding area are expected to be similar to those at the Project and WTC sites.

The sub-grade Route 9A connection would be located on the western edge of the bathtub at Route 9A and would be constructed through three surficial soil deposits. Based on geologic cross sections compiled at the former Battery Place to Harrison Street bulkheads, the uppermost unit is composed of miscellaneous fill material including mixed clay, silt, sand, gravel, cinders and occasional boulders (Moran et. al., 1942). Historical cross-sections as well as the National Academy of Engineering refer to the deposits as "fill". This material is approximately 5-20 feet

in thickness (Tamaro, 2002). The second layer of sediment is up to 20 to 35 feet in thickness and consists of native soft dark gray, organic clayey silts with trace fine sand (Moran et. al., 1942). These deposits are associated with Hudson River channel deposits. The third layer of sediment underlying this location is native medium compact to compacted gray silty fine to coarse sand, with trace to some gravel. These deposits are also Hudson River channel deposits. It has been documented by the National Academy of Engineering that a quartzite knoll intrudes on the basin in the southwest corner of the site. The depth or size of outcrop in this area is unclear.

Ground Water

Due to the proximity of the Project Site to the Hudson River, uppermost ground water would be expected to be present relatively near the surface. However, given the presence of the slurry wall, ground water is precluded from entering the physical limits of the Project Site from perimeter areas. Ground water below the Project Site, within the underlying bedrock, is anticipated at approximately 100 feet below surface grade. Ground water at the surrounding WTC site is reported to be variable and controlled by dewatering at the Hudson & Manhattan Coffer Dam, located along Church Street between Vesey and Liberty Streets. The dewatering was performed prior to September 11, 2001 to prevent ground water infiltration into the subgrade structures and will be continued permanently. Ground water resources in Manhattan are not used for potable purposes.

HISTORICAL USES

The identification of historical uses provides essential information with respect to the potential for contaminated materials to be present at or in the vicinity of the Project Site as prior operations/activities often include the use of hazardous materials and may result in impacts to environmental media. Therefore, in conjunction with the environmental review process, historical information sources were reviewed to establish existing site and area conditions. The historical information sources used for this project included historical aerial photographs, Sanborn Fire Insurance Maps, historical topographic, and United States Geologic Survey (USGS) maps. Six historical aerial photographs (1943, 1953, 1966, 1976, 1985, and 1995), 156 Sanborn Maps (1894, 1922, 1923, 1928, 1950, 1977, 1978, 1979, 1980, 1981, 1983, 1985, 1987, 1988, 1991, 1992, 1993, 1994, 1995, and 1996) and five historical topographic maps (1900, 1947, 1955, 1967, and 1981) were reviewed to document historical uses of the Project Site and surrounding area. In addition, historical Jersey City, New Jersey, USGS Topographic Quadrangle Maps depicting the Project Site and the surrounding area were reviewed to obtain additional information with regard to prior area usage. The Jersey City, New Jersey, USGS maps are based on surveys dated 1900, 1947, 1955, 1967, and 1981 photo-revised from 1967.

Overall, a review of the various historical information sources identifies primarily mixed commercial uses as well as the presence of transportation elements such as the New York City Transit (NYCT) 1 and 9 line and the Hudson and Manhattan (H&M) Railroad Terminal at the Project Site prior to the development of the WTC complex. These data sources identify that coastal features (i.e., the Hudson River) were formerly located in closer proximity to the Project Site, thus providing the technical basis for the placement of fill at the Project Site in conjunction with initial development. Generally, most of lower Manhattan was raised in grade and extended westward by the emplacement of non-native fill material. Some time after 1609 but prior to 1900, the eastern bank of the Hudson River was located at the current location of Greenwich Street. Various sources document that fill material consisted of a variety of materials ranging from dredged sediment from the Hudson River to old shoes (Tamaro, 2002).

The historical information sources identify the presence of a combination of multi-family residential uses, commercial uses including retail shops, stores and restaurants, and Washington Square, as well as some light industrial uses at the Project Site during the late 1800s and early 1900s. Mapping for this era identifies boilers and tanks at individual sites, primarily south of Dey Street. These sources reveal an increase in commercial usage with a corresponding decrease in residential uses at the Project Site and during the 1940s and 1950s. In particular, a gasoline station is identified at the northwestern portion and a gasoline filling station including several aboveground storage tanks is identified at the southwestern portion of the Project Site during this time period. Review of the historical information sources does not identify any major changes in usage at the Project Site or the adjacent area to the east until the development of the WTC site in the mid- to late-1960s. Although contaminants associated with prior uses may have impacted environmental media, construction of the WTC site included the razing of structures, removal of most soil to bedrock, and installation of a concrete slab over much of the western portion of the Project Site. As such, a low potential for residual contamination existed during the time frame of the WTC site.

DOCUMENTED ENVIRONMENTAL CONTAMINATION ISSUES

To fully characterize the affected environment of the Project Site and surrounding area, it is necessary to determine if environmental contamination has been identified at the Project Site or sites in the surrounding area. Therefore, an electronic file search of federal and state regulatory environmental databases was obtained through a commercial source, Environmental Data Resources (EDR). The report provided as a result of the search includes information related to sites included on regulatory lists as well as a map identifying the location of the listed sites with respect to the Project Site. A copy of the electronic file search is provided in Appendix F. Review of the EDR Report did not reveal the inclusion of the PATH Terminal on any of the reviewed regulatory databases. However, the Port Authority of New York and New Jersey (PANYNJ) at the 1 WTC location is included on the New York State Department of Environmental Conservation (NYSDEC) Underground Storage Tank (UST) database. The listing identifies the former presence of a 55-gallon UST, which was removed by the PANYNJ. The listing also provides information related to aboveground storage tanks (ASTs) located at the WTC site. The listing identifies the presence of six ASTs containing petroleum products. The listing does not identify any environmental contamination issues with regard to the presence or use of these ASTs or the former UST. With regard to the surrounding area, a number of sites are included in the NYSDEC UST List. The listings do not identify any environmental contamination issues at area sites that have impacted the Project Site. However, the UST and ASTs are no longer on the site and there is a low potential for residual contamination.

Review of the EDR Report identifies a number of WTC site tenants on regulatory lists associated with the permitted use and storage of certain materials considered hazardous by the EPA and/or the NYSDEC. The EDR Report also identifies that several sites within the surrounding area that are also included in regulatory databases associated with the permitted use and storage of hazardous materials. No contamination issues are identified with respect to these listings. The WTC site is also included on the NYSDEC Spills List (NY SPILLS). Several occurrences of minor petroleum product discharges are identified during the 1990s. The specific locations of the spills within the WTC site are not identified in the database listings. It should be noted that a representative of the NYSDEC has stated all open tank and spill matters associated with the WTC have been closed. Confirmation of the case closure is forthcoming.

Overall, review of environmental database information has not revealed environmental contamination issues at the Project Site or issues within the surrounding area with the potential to impact the Project Site.

The potential presence of hazardous materials subsequent to September 11, 2001, including database listings on or after that date, is further described below.

HAZARDOUS MATERIAL STORAGE AREAS

The WTC site included areas used by the PANYNJ as well as numerous tenants. A Community Right-To-Know (RTK) Survey was performed for the areas of the complex occupied or used for storage of hazardous materials by the PANYNJ. Review of the Year 2000 RTK Survey did not reveal the presence of hazardous materials used or stored in the former WTC PATH Terminal located below the WTC site. According to information gained through the survey, maintenance of the PATH trains servicing the WTC site was performed at the PATH Harrison Maintenance Facility in New Jersey.

CHANGES IN THE AFFECTED ENVIRONMENT SINCE SEPTEMBER 11, 2001

The terrorist attacks of September 11, 2001 resulted in the collapse of the WTC complex and the majority of the subgrade structures located beneath the complex, including the PATH Terminal, components of the PATH system, and associated concourse, egress routes, etc. The Project Site (PATH Terminal portion of the Project Site) currently lies at approximately 65-70 feet below street grade. No permanent buildings are located within the limits of the Project Site or the adjacent eastern portion of the WTC site. The temporary PATH station is presently located at the Project Site. The discussion of the affected environment pre-September 11, 2001 included information pertaining to geology and landform, historical uses, and environmental conditions as identified through a review of regulatory databases and other information sources. The discussion of geology and landform and historical uses is not required for this further discussion of the affected environment. However, this section provides information pertaining to hazardous materials issues as a result of September 11, 2001 and the subsequent removal effort. Although hazardous materials issues resulting from September 11, 2001 are provided in this section for completeness, the subsequent recovery effort included the removal of all material, debris, and soil from within the Project Site, thereby eliminating environmental contamination issues with respect to the Project Site.

The collapse of the WTC site resulted in the identification of the following concerns with regard to hazardous materials:

- Debris, including asbestos, LBP and PCBs, deposited on the site due to the collapse and demolition of the buildings and structures located on the WTC site;
- Dielectric oils from transformers and cables feeding the WTC complex from the former 7 WTC building;
- Hazardous materials stored at the site and used by WTC site tenants; and
- Fill material reportedly located beneath the WTC complex buildings.

These issues are related to the entire WTC site and not specifically to the Project Site as defined for this Environmental Impact Statement (EIS).

As stated above, an electronic file search of regulatory databases was performed as part of the contaminated materials assessment of the EIS process. The EDR Report provides information pertaining to listings for both pre- and post-September 11, 2001 conditions. With respect to post-September 11, 2001 conditions, the EDR Report identifies the inclusion of the WTC site in the NYSDEC Spills List for September 11, 2001. The listings are consistent with the previously described hazardous materials concerns and identify the discharge of dielectric fluid, asbestos, and transformer oil. The presence of the documented materials has been addressed in conjunction with the removal efforts performed at the Project Site. In addition, a few sites within the surrounding area are listed with spills/discharges involving petroleum products, which occurred on September 11, 2001 or shortly thereafter. Generally, these occurrences appear to be associated with discharges of petroleum products from equipment and vehicles used in recovery efforts. The listings do not identify a continuing environmental contamination issue with regard to the occurrences and the NYSDEC reportedly closed the cases in December 2003.

Subsequent to the terrorist attacks, rescue, recovery, and removal efforts were undertaken from September 11, 2001 to June 30, 2002. Generally, the area defined as the Project Site was excavated to the remaining bottom slab of the former structures. Soils near the projections of the PATH tunnels were retained; however, the top 18 inches were removed and replaced with clean fill. The eastern portion of the WTC site was excavated to depths ranging from street grade to 35 feet below street grade.

According to regulatory agencies overseeing the removal efforts, soils and hazardous materials that may have been present in the western portion of the WTC site as a result of historical operations and the terrorist attacks have been either removed or burned, or a combination of the two. However, it has been acknowledged that soils located to the east of the NYCT's 1 and 9 line may contain residual contamination from historical operations and the terrorist attacks. This area is being addressed pursuant to a separate development action as part of the *World Trade Center Memorial and Redevelopment Plan Generic Environmental Impact Statement (GEIS)*. No changes have been identified with regard to the other pedestrian egress routes that extend from the PATH Terminal and which have been included as part of the Project Site. These additional areas have not been identified as having been impacted by hazardous materials with respect to the terrorist attacks.

Materials formerly present on the Project Site were subjected to the fallout (dust and debris) generated from terrorist attacks. Analytical results presented by the U.S. Environmental Protection Agency (EPA) indicated that the dust and debris resulting from the attacks potentially contained contaminants such as asbestos, dioxins, polychlorinated biphenyls (PCBs) and certain metals (EPA 2002 and 2003 Reports). However, as noted above, removal efforts that occurred during the nine months following the terrorist attacks resulted in the excavation/removal of the materials located within the limits of the Project Site as well as from area locations. As part of the *World Trade Center Memorial and Redevelopment Plan GEIS*, the Lower Manhattan Development Corporation (LMDC) performed a Hazardous Materials Screening Study, which included the conductance of soil and ground water sampling and analysis. The sampling was performed at locations at the eastern portion of the WTC site as well as at locations beyond the limits of the WTC site.

The results of the sampling are detailed in the *WTC Memorial and Redevelopment Plan GEIS*. Briefly, the soil sampling program revealed the presence of relatively few contaminants at concentrations above regulatory thresholds. In fact, the sampling revealed the presence of only metals at concentrations in excess of regulatory guidelines. Beryllium, chromium, copper,

magnesium, lead, mercury, nickel, selenium, and zinc were detected at elevated concentrations in surficial soils collected from the eastern portion of the WTC Site as well as from soil present at the former grade at 140 Liberty Street and at intersection of Washington and Albany Streets. The metals detected at elevated concentrations are considered typical fill contaminants and consistent with background conditions at urban sites. EPA air monitoring data revealed that beryllium, mercury, and selenium were not detected in samples collected in the vicinity of WTC Site subsequent to September 11, 2001. Chromium, copper, magnesium, nickel, selenium, and zinc were detected, but at low concentrations. The EPA detected elevated concentrations of lead in air, but the concentrations fell below the EPA's benchmark within one month of September 11, 2001. Although elevated concentrations of these metals may be present in surficial and subsurface soils, their absence or low concentrations in the air subsequent to September 11, 2001 indicate that they are not an ongoing source of exposure. The lateral and vertical distribution of these metals throughout the Project Site indicates that they are not likely to be associated with historic releases; rather that these metals' concentrations are representative of background conditions in the vicinity of the Project Site.

Elevated concentrations of arsenic, chromium, lead, manganese, mercury, nickel, and selenium were detected in samples collected from the surfaces of existing structures located along the perimeter of the eastern portion of the WTC Site. The concentrations of these metals exceed the EPA's benchmarks for residences. Based on their distribution and concentrations, it is likely that these samples reflect material deposited as a result of September 11, 2001. Trace concentrations of dioxin were detected in surficial soil samples and in samples collected from the surfaces of existing structures, significantly below EPA remediation criterion.

Soil sampling did reveal trace concentrations of asbestos in surficial soil collected from the eastern portion of the WTC site. However, the concentrations detected are considered typical background conditions in urban settings such as the Project Site. Further, EPA air monitoring performed at and in the vicinity of the WTC site has not revealed concentrations of airborne asbestos above screening level. In fact, asbestos has not been detected in the vast majority of air samples.

Similar to the soil results, the ground water sampling revealed the presence of relatively few contaminants. Specifically, ground water sampling revealed the presence of only a single volatile organic compound (VOC) at a concentration marginally above the NYSDEC GA standards in one sample from the eastern portion of the WTC site, but were below NYCDEP sewer discharge requirements. Chloroform was detected in a single sample collected from the eastern portion of the WTC site. The presence of chloroform in ground water is likely to be associated with the usage of buried/subsurface water lines holding and transferring chlorinated water; chloroform is a byproduct of the chlorinating process. In addition, chloroform, toluene, and benzene were detected at concentrations above NYSDEC regulatory standards for potable water in a sample collected from the intersection of Washington and Albany Streets, south of the WTC site. The presence of toluene and benzene may be the result of a petroleum discharge unlikely to be related to the Project Site, and the presence of chloroform is likely to be attributable to the extensive subsurface water lines in this portion of Manhattan.

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

CONSTRUCTION PERIOD (2006)

FUTURE COMMON TO ALL ALTERNATIVES

The Future Common to All Alternatives considers actions undertaken by others, which are independent of the Preferred Alternative. No contaminated building materials or environmental media have been identified within the limits of the west "bathtub" of the WTC site, as remaining debris and soil material were removed in conjunction with the September 11, 2001 recovery effort. Therefore, development within the west "bathtub" in association with the WTC Memorial and Redevelopment Plan would not encounter hazardous materials.

As described above, portions of the WTC site east of the 1 and 9 line have the potential for residual contamination since debris and structures remain in this area. Similar to efforts associated with the Preferred Alternative, LMDC will prepare a Health and Safety Plan (HASP) that includes remedial measures for the excavation and removal of these materials in association with their demolition and subsequent construction efforts.

There is also the potential for contamination within the limits of the Route 9A Project, which also includes the area of PATH's proposed east-west connection to the World Financial Center and the north and south ventilation structures. The New York State Department of Transportation will also prepare a Health and Safety Plan (HASP) for the Route 9A Project that would include specific measures to remove and dispose of any contaminated soils or groundwater encountered during construction. If NYSDOT pursues the short-bypass alternative for the Route 9A Project, the HASP would include the areas of PATH's east-west connection beneath Route 9A and the north and south ventilation structures..

Overall, construction activities at the Project Site are not anticipated to create or exacerbate existing contaminated material conditions at other area project sites. Further, no major contamination issues have been identified at planned development or redevelopment sites in the surrounding area. Thus, development/redevelopment actions undertaken by others at area sites are unlikely to adversely impact the project site with respect to contaminated materials.

NO ACTION ALTERNATIVE

Under the No Action Alternative for the construction period, no construction activities would be occurring with respect to the Permanent WTC PATH Terminal. However, development activities would continue to occur at surrounding areas including the WTC site (WTC Memorial and Redevelopment Plan). Given the developed nature of the surrounding area, it is unlikely that development efforts at area sites would cause any contaminated materials issues at the Project Site. This conclusion assumes that all area development projects would use appropriate construction methods and remediation. With respect to activities assumed to occur in the redevelopment of the overall WTC site, the potential exists for any contaminants in soil remaining at that location to impact the Project Site. However, recent studies conducted for the *World Trade Center Memorial and Redevelopment Plan GEIS* did not reveal major contaminant issues at that site. Additional actions for that project would include further evaluation of soil quality and the removal and appropriate disposal of soil. Therefore, no adverse impacts with respect to contaminated materials are anticipated under the No Action Alternative.

PREFERRED ALTERNATIVE

The construction of the Preferred Alternative would result in minimal changes to existing environmental media within the "west bathtub" of the WTC site. As previously described, all debris from the September 11, 2001 attacks on the WTC site and most soil present at this portion of the site were removed during recovery efforts. Soils near the projections of the PATH tunnels were retained; however, the top 18 inches were removed and replaced with clean fill.

Portions of the basement wall within the WTC site were damaged during the attacks. As a result, PANYNJ has installed pumps to discharge any ground water that leaks into the site in addition to collected stormwater. As part of this project, PANYNJ would repair portions of the basement walls (see Chapter 2, "Project Alternative"). The rehabilitated basement walls would essentially eliminate the invasion of overburden ground water through the wall into the WTC site.

The Preferred Alternative includes the construction of pedestrian egress from the Terminal to street level at several locations as well as two ventilation structures within the median of Route 9A. The construction would include excavating/tunneling to the eastern portion of the WTC site beneath the existing 1 and 9 subway tracks as well as similar activities at perimeter locations along Route 9A.

There is potential that excavation/tunneling activities associated with the proposed egress routes on the eastern portion of the WTC site may encounter fill material, which could include contaminants and/or contaminated ground water. Given the urban nature of the project site and the perimeter areas, the presence of fill material containing low levels of contaminants is expected and, if identified, will be addressed in conjunction with the proposed project. Similar actions will be undertaken with respect to ground water. Actual construction activities at the Project Site will be performed using appropriate construction and engineering practices, which include awareness of contaminant issues.

The potential also exists that excavation/tunneling activities associated with the proposed Route 9A connection and the north and south ventilation structures may encounter fill material, which could include contaminants and/or contaminated ground water. The 1994 *Route 9A Reconstruction Final Environmental Impact Statement* showed testing results for the Route 9A alignment, including the area that would contain the ventilation structures and the proposed pedestrian connection. These results showed elevated levels of polycyclic aromatic hydrocarbons (PAHs) and metals at a depth of approximately 24 feet below the surface of Route 9A, and such contaminants are typical of fill soils in New York City.

Regardless of contaminant concentrations, construction activities would be performed using appropriate construction and engineering practices, which include awareness of contaminant issues. In addition, prior to the initiation of the construction activities at the perimeter areas, a site-specific HASP would be prepared and implemented to protect the general public and workers from exposure to contaminants present in air, soil, ground water, building materials, and buried structures (utilities) encountered at the site. The HASP would include worker training and required safety courses, monitoring requirements, use of personal protection equipment (PPE), contaminant action levels, and air monitoring equipment. Further, the HASP would address preventative measures to narrow down or eliminate potential exposure pathways and corrective actions if exposure occurs. If contaminant concentrations are exceeded during the construction phase, then all activities would cease and the appropriate remedial actions would be undertaken to address the issue at hand as noted in the HASP.

As part of the HASP, management plans for soil, dust, ground water, asbestos, and PCBs would be implemented. The management plans would contain the methods to be used in handling, staging, disposal, transportation, and decontamination of equipment and personnel in accordance with local, state, and federal regulations. Further, the management plans would contain a list of licensed waste haulers and disposal facilities that could legally accept hazardous materials that may remain on the Project Site.

The potential hazardous materials on the Project Site are typical for urban sites in New York City. Some of the federal, state, and local regulations that govern their proper handling, removal, and disposal include:

- U.S. EPA, Identification and Listing of Hazardous Waste (40 CFR Part 261);
- U.S. EPA, Standards Applicable to Generators of Hazardous Waste (40 CFR Part 262);
- U.S. EPA, Standards Applicable to Transporters of Hazardous Waste (40 CFR Part 263);
- U.S. EPA, Standards for Owners and Operators of Hazardous Waste Treatment, Storage, and Disposal Facilities (40 CRF Part 264);
- U.S. EPA, Interim Status Standards for Owners and Operators of Hazardous Waste Treatment, Storage, and Disposal Facilities (40 CFR Part 265);
- U.S. EPA, Standards for the Management of Specific Hazardous Wastes and Specific Types of Hazardous Waste Management Facilities (40 CFR Part 266);
- U.S. EPA, Land Disposal Restrictions (40 CFR Part 268);
- New York State Solid and Hazardous Waste Regulations (6 NYCRR Part 360) for remediation of soils that have elevated levels of metals as well as residual asbestos on the site.
- Procedures in Petroleum Cleanup and Removal (6 NYCRR Part 613 and 6 NYCRR Part 611) for removal of any storage tanks;
- Spill Technology and Remediation Series (STARS) Memo #1 for removal and disposal of petroleum contaminated soil; and
- Technical and Operations Guidance Series (TOGs) for removed of petroleum contaminated groundwater.

The Project's HASP would include procedures for the handling and disposal of any encountered materials in accordance with these regulations and with other guidance and protocols of EPA, NYSDEC, and the New York City Department of Environmental Protection.

Construction activities performed at the site are likely to include the use of petroleum products associated with equipment and machinery operations. All materials would be maintained in accordance with project health and safety plans and in conformance with the local, state, and federal regulations noted above. Adherence to applicable regulation and appropriate construction practices would avoid impacts to human health and the environment. The types of petroleum materials are similar to those used to fuel roadway vehicles present on a daily basis throughout the surrounding area. As such, it is not anticipated that the use of such materials would have a deleterious impact on the surrounding environment.

Overall, no contaminated materials issues are anticipated for this alternative during the construction period.

OPENING YEAR (2009)

FUTURE COMMON TO ALL ALTERNATIVES

Construction activities will continue in Lower Manhattan in the opening year, including the development of the WTC site as part of the WTC Memorial and Redevelopment Plan. However these area redevelopments are not anticipated to result in any contaminated materials impacts, as described in the "Construction Period" section above.

NO ACTION ALTERNATIVE

In the opening year, the temporary WTC PATH station would continue to operate in its current location. As stated above, development activities would continue in surrounding areas including the WTC site. It is unlikely that further development efforts would cause any contaminated materials issues at the Project Site based on the conclusion that all area projects would use appropriate construction methods and remediation. Therefore, no adverse impacts with respect to contaminated materials are anticipated with the No Action Alternative in the opening year.

PREFERRED ALTERNATIVE

Construction activities associated with the Preferred Alternative would be concluded by the opening year. Thus, no disturbance of environmental media would be anticipated under this scenario. If any contaminated materials were encountered during construction, such materials would have been removed or isolated in accordance with applicable regulations prior to and/or during the construction phase, and no potential would exist for workers or the public to contact same.

Operation of the PATH train system would include the use of limited quantities of hazardous materials and petroleum products. However, these materials are used for the current system and, as previously stated; such materials are not stored and would not be stored on the WTC site. The PANYNJ has not proposed any changes in materials handling for the PATH system; thus, hazardous materials storage would remain off-site. Although the general maintenance and cleaning of PATH trains would continue to occur at PATH's facilities in Jersey City and Harrison, limited emergency maintenance may occur at the WTC Terminal when trains must be pulled out of service. The PANYNJ has established a series of standard operating procedures, which include measures to be undertaken in the event of a discharge of hazardous materials or petroleum products. These procedures would continue to apply in the opening year, including future actions at the Project Site.

Thus, no adverse impacts with respect to contaminated materials are anticipated for the Preferred Alternative in the opening year.

DESIGN YEAR (2025)

FUTURE COMMON TO ALL ALTERNATIVES

Redevelopment performed at area sites in the time period between the opening year and the design year is not anticipated to result in any contaminated materials issues.

NO ACTION ALTERNATIVE

The No Action Alternative would not include the presence of a Permanent WTC PATH Terminal in the design year. Furthermore, the temporary WTC PATH station would not be in operation. All other portions of the WTC site redevelopment would be complete. With respect to these activities, any remaining contamination on the site would have been removed during the construction period. Therefore, no contaminated materials issues are anticipated under the No Action Alternative in the design year.

PREFERRED ALTERNATIVE

With respect to contaminated materials, the impact analysis for the Preferred Alternative for the design year is identical to that presented for the opening year. Thus, no adverse impacts with respect to contaminated materials are anticipated for this alternative in the design year.

E. MITIGATION

No adverse impacts with respect to contaminated materials are anticipated for the Preferred Alternative in the construction period, opening year, or design year. However, as previously stated, construction activities will be performed using appropriate construction and engineering practices, which include awareness of contaminant issues. In addition, prior to the initiation of the construction activities at the perimeter areas, a site-specific HASP will be prepared and implemented to protect the general public and workers from exposure to contaminants present in air, soil, ground water, building materials, and buried structures (utilities) encountered at the site. The HASP will include worker training and required safety courses, monitoring requirements, use of personal protective equipment (PPE), contaminant action levels, and air monitoring equipment. Further, the HASP will address preventative measures to eliminate or minimize potential exposure pathways.

The HASP will be required as part of contract documents and will be in conformance with the above described goals/objectives and will include elements outlined in the following framework:

- Identification of potential contaminants and, as necessary, development of a soil or ground water sampling plan to determine contaminant concentrations in environmental media;
- Identification of thresholds or action levels for contaminants and development of procedures for modification or cessation of work activities based on field screening result;
- Worker health and safety training including the identification of a project health and safety officer who will be responsible for overall oversight and will maintain all appropriate documentation of safe working conditions and permits/approvals for the management of construction related wastes and residuals;
- Development and implementation of field screening for contaminant detection and worker health and safety;
- Identification of PPE to be used (worn) during specified phases of construction;
- Development and implementation of a Soil Management Plan identifying the methods to be used in handling, staging, disposal, transportation, and decontamination of equipment and personnel in accordance with local, state, and federal regulations;

- Development and implementation of a Ground Water Management Plan to address dewatering actions from ground water infiltration and overland stormwater and the methods to be used in handling, staging, disposal, transportation, and decontamination of equipment and personnel in accordance with local, state, and federal regulations;
- Development and implementation of a Dust Management Plan to address dust generated through excavation or general construction activities;
- Development and implementation of management plans to address PCBs and asbestos; and,
- Identification of proposed licensed waste haulers and disposal/recycling facilities, for the transportation and disposal/recycling of waste materials generated from the project.

The project specific HASP will be in accordance with all applicable local, state, and federal regulations and will document that safe conditions relative to onsite workers and the public are maintained throughout the project. ✷

A. INTRODUCTION

This chapter assesses the potential impacts to terrestrial and aquatic natural resources from the construction and operation of the Preferred Alternative. With the exception of the terminal building, street-level entrances, emergency egress and ventilation structures, elements of the Preferred Alternative would be below ground.

The street-level terminal building would be located on the western side of Church Street between Dey and Fulton Streets (see Chapter 7, "Urban Design and Visual Resources"). As currently proposed, the above-ground terminal would comprise of an oblong glass and steel shell, the roof of which would contain two counterpoised glass wings that would rise more than 100 feet into the air and extend the length of the building (about 350 feet). The structure would allow natural light to illuminate the terminal concourse. The ceiling of the aboveground building may have the capacity to open up to the sky, between the two wing-like structures. It would not be higher than the towers proposed as part of the WTC Memorial and Redevelopment Plan that would be constructed near it. The perimeter of the street-level terminal would be landscaped.

The Terminal would include street-level access from other locations within the WTC site. These entrances would be located within the proposed offices towers and other structures associated with the WTC Memorial and Redevelopment Plan. An additional entrance would be provided west of Route 9A in front of the Winter Garden. Two ventilation structures with emergency egress would be located within the median of Route 9A. Two additional emergency egress stairways from the PATH platforms and mezzanine would be located within the WTC site west of the 1 and 9 line.

The Preferred Alternative would not involve any in-water construction in the Hudson River nor would it involve construction within a wetland. However, the Terminal would tie into the re-establishment of the river cooling system on the WTC site once it becomes available. The re-establishment of the river water cooling system is being undertaken as a separate action; therefore, as described in Chapter 2, "Project Alternatives," the Permanent WTC PATH Terminal would employ alternative cooling methods until the river water cooling system is fully operational. Additionally, the implementation of "green" design, "green" construction, and sustainable design principles described in Chapter 2, "Project Alternatives," would reduce the potential for adverse environmental impacts from the Preferred Alternative. Measures include, but are not limited to, energy-efficient lighting, heating and ventilation systems, and development of a Comprehensive Energy Management Plan, Comprehensive Resource Management Plan, and Water Management Plan, described in Chapter 11, "Infrastructure and Energy." These measures would contribute to the conservation of energy and water resources, thereby reducing potential environmental impacts associated with power generation on a regional scale, and possibly resulting in a decrease in the cooling water needs for the Preferred Alternative.

B. METHODOLOGY

DATA SOURCES

Natural resources within the affected environment (Project Site and the Hudson River in the vicinity of the WTC intake) are described for two baseline conditions: pre-September 11, 2001; and changes to the affected environment since September 11, 2001. The description of natural resources for these two baseline conditions was developed on the basis of:

- Existing information identified in literature and obtained from governmental and non-governmental agencies such as: Port Authority of New York and New Jersey (PANYNJ), NYSDEC, New York City Department of Environmental Protection (NYCDEP) Harbor Water Quality Surveys (NYCDEP 1998, 2000, 2001, 2002, 2003a and b), U.S. Environmental Protection Agency (EPA) (e.g., Regional Environmental Monitoring and Assessment Program (R-EMAP) (Adams et al. 1998)), U.S. Army Corps of Engineers (ACE), Federal Emergency Management Agency (FEMA) flood insurance rate maps, and the Interstate Environmental Commission (IEC).
- Observations made at the Project Site.
- Responses to requests for information on rare, threatened or endangered species within ½ mile surrounding the site of the Preferred Alternative and the WTC cooling water intake. These requests were submitted to the U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NMFS), and the New York Natural Heritage Program (NYNHP). NYNHP, a joint venture of NYSDEC and The Nature Conservancy since 1985, maintains an ongoing, systematic, scientific inventory on rare plants and animals native to New York State. NYSDEC maintains the NYNHP files. The NYNHP database is updated continuously to incorporate new records and changes in the status of rare plants or animals. In addition to the state program, the USFWS maintains information for federally listed threatened or endangered freshwater and terrestrial plants and animals, and the NMFS for federally listed threatened or endangered marine organisms.

REGULATORY FRAMEWORK

The following sections briefly describe the federal and state laws and associated regulations and regulatory programs that may apply to the Preferred Alternative with respect to terrestrial resources, water quality, and aquatic resources that are found within the vicinity of the WTC site and the WTC intake and outfalls. The regulations apply to certain activities in coastal areas and surface waters, and to the protection of species of special concern.

FEDERAL

The Clean Water Act (33 USC §§ 1251 to 1387)

The objective of the Clean Water Act, also known as the Federal Water Pollution Control Act, is to restore and maintain the chemical, physical, and biological integrity of U.S. waters. It regulates point sources of water pollution such as discharges of municipal sewage and industrial wastewater, and non-point source pollution such as runoff from streets, agricultural fields, construction sites and mining that enter waterbodies, from other than the end of a pipe. Section 402 of the Clean Water Act establishes the National Pollutant Discharge Elimination System (NPDES) which governs the review and issuance of permits for the discharge of pollutants to

surface waters. Section 402 also allows the EPA to delegate authority to states to carry out the NPDES program once they have met the specified requirements. New York has been delegated authority to implement NPDES, which it does through the State Pollutant Discharge Elimination System (SPDES), as discussed below in the section on New York regulations.

In addition, any applicant for a federal permit or license for an activity that may result in a discharge to navigable waters must provide to the federal agency issuing a permit a certificate, either from the state where the discharge will occur or from an interstate water pollution control agency, that the discharge will comply with Sections 301, 302, 303, 306, 307, and 316 (b) of the Clean Water Act. Applicants for discharges to navigable waters in New York must obtain a Water Quality Certificate from NYSDEC.

Coastal Zone Management Act of 1972 (16 USC §§ 1451 to 1465)

The Coastal Zone Management Act of 1972 established a voluntary participation program to encourage coastal states to develop programs to manage development within the state's designated coastal areas to reduce conflicts between coastal development and protection of resources within the coastal area. Federal permits issued in New York must be accompanied by a Coastal Zone Consistency Determination that evaluates consistency with New York's federally approved coastal zone management program.

Executive Order 11988, Floodplain Management

Executive order 11988 states that, "each agency shall provide leadership and shall take action to reduce the risk of flood loss, to minimize the impact of floods on human safety, health and welfare, and to restore and preserve the natural and beneficial values served by floodplains in carrying out its responsibilities."

Magnuson-Stevens Act (16 USC §§ 1801 to 1883)

Section 305(b)(2)-(4) of the Magnuson-Stevens Act outlines the process for the NMFS and the Regional Fishery Management Councils (in this case, the Mid-Atlantic Fishery Management Council) to comment on activities proposed by federal agencies (issuing permits or funding projects) that may adversely impact areas designated as essential fish habitat (EFH). EFH is defined as those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity (16 USC §1802(10)).

Endangered Species Act of 1973 (PL 93-205; 16 USC 1531 to 1544)

The Endangered Species Act of 1973 recognized that endangered species of wildlife and plants are of aesthetic, ecological, educational, historical, recreational, and scientific value to the nation and its people. The Act prohibits the importation, exportation, take, possession, and other activities involving illegally taken species covered under the Act, and interstate or foreign commercial activities. The Act also provides for the protection of critical habitats on which endangered or threatened species depend for survival. USFWS (non-marine plants and animals) and NMFS (marine plants and animals) are responsible for administering the Act. Section 7(a) of the Act requires federal agencies to consult with the Secretary of the Interior (through USFWS and/or NMFS) before project implementation to ensure that the proposed action will not jeopardize a species, or destroy or adversely modify the designated critical habitat of the species.

Migratory Bird Treaty Act (16 USC §§703 to 712)

The Migratory Bird Treaty Act implements the United States' commitment to four bilateral treaties, or conventions, for the protection of a shared migratory bird resource. Each of the treaties protects selected species of birds and specifies basic closed and open seasons for hunting game birds. The Act makes it illegal for anyone to take, possess, import, export, transport, sell, purchase, barter, or offer for sale, purchase or barter, any migratory bird, or the parts, nests, or eggs of such a bird except under the terms of a valid permit issued pursuant to federal regulations. Title 50, Section 10.13, of the Code of Federal Regulations (50 CFR 10.13) lists the bird species protected under the Act.

STATE

State Pollutant Discharge Elimination System (SPDES), Article 17 Title 8, ECL, Implementing Regulations 6 NYCRR Parts 750, 751, 752, 753, 754, 755, 756, 757.

Title 8 of Article 17, ECL, Water Pollution Control, was enacted to protect and maintain surface and ground water resources and authorized the creation of the State Pollutant Discharge Elimination System (SPDES) to regulate discharges to the state's waters. The following activities require SPDES permits: constructing or using an outlet or discharge pipe (point source) that discharges wastewater into surface or ground waters of the State; constructing or operating a disposal system (sewage treatment plant); or discharge of stormwater. Construction activities that disturb one acre or more must obtain an SPDES permit.

SPDES addresses thermal discharges in ECL §§15-0313 and 17-0301, and the implementing regulations in 6 NYCRR Parts 704 and 750. Title 3 (Powers and Duties) of Article 15 (Water Resources), ECL, and Title 3 (Jurisdiction of the NYSDEC Authority, Powers and Duties) of Article 17 (Water Pollution Control), ECL, authorizes NYSDEC to establish water quality standards for thermal discharges to the waters of New York State, as implemented in 6 NYCRR Chapter X (Division of Water Resources) Part 704 (Criteria Governing Thermal Discharges) and Part 750 (SPDES). The thermal discharge criteria established in 6 NYCRR Part 704 include general criteria for waters receiving thermal discharges; special criteria specific to different types of State waters receiving thermal discharges; mixing zone criteria; and the requirement that the location, design, construction and capacity of cooling water intake structures for a point source thermal discharge reflect the best technology available for minimizing adverse environmental impact.

Waterfront Revitalization of Coastal Areas and Inland Waterways Act (Executive Law Sections 910-921).

Under this Act, the New York State Department of State (NYSDOS) is responsible for administering the Coastal Management Program (CMP). The Act also authorizes the State to encourage local governments to adopt Waterfront Revitalization Programs (WRP) that incorporate the State's policies. New York City has a WRP administered by the Department of City Planning.

Floodplain Management Criteria for State Projects (6 NYCRR 502)

Under 6 NYCRR 502, all state agencies are to ensure that the use of state lands, and the siting, construction, administration and disposition of state-owned and state-financed projects involving any change to improved or unimproved real estate are conducted in ways that will minimize flood hazards and losses. Projects are to consider alternative sites on which the project could be

located outside the 100-year floodplain. Projects to be located within the floodplain are to be designed and constructed consistent with the need to minimize flood damage within the 100-year floodplain and include adequate drainage to reduce exposure to flood hazards. All public utilities and facilities associated with the project are to be located and constructed to minimize or eliminate flood damage. The regulations specify that for nonresidential structures, the lowest floor should be elevated or flood-proofed to not less than one foot above the base flood level so that below this elevation the structure, together with associated utility and sanitary facilities, is watertight, with walls substantially impermeable to the passage of water and with structural components having the capability of resisting hydrostatic and hydrodynamic loads and effects of buoyancy. No project may be undertaken unless the cumulative effect of the proposed project and existing developments would not cause material flood damage to the existing developments. In cities with a designated floodway, no portion of the project may be placed within the adopted regulatory floodway to result in any increases in flood levels. The only regulatory floodway in New York City is the Bronx River, which is outside the Project Site.

Endangered and Threatened Species of Fish and Wildlife; Species of Special Concern, ECL, Sections 11-0535[1]-[2], 11-0536[2], [4], Implementing Regulations 6 NYCRR Part 182.

The Endangered and Threatened Species of Fish and Wildlife; Species of Special Concern Regulations prohibit the take, import, transport, possession or selling of any endangered or threatened species of fish or wildlife, or any hide, or other part of these species as listed in Section 182.6.

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

PRE-SEPTEMBER 11, 2001 BASELINE CONDITIONS

TERRESTRIAL RESOURCES

Before the terrorist attacks, the Project Site was occupied by the WTC PATH terminal (track and platform level, mezzanine/fare-zone level, and sub-grade pedestrian connections to adjacent streets, subways, and the WTC) within the portion of the WTC complex known as the "bathtub." The terminal had no above-ground features and was accessed through buildings within the WTC complex. Overlying the WTC PATH Terminal were the WTC's office and retail space. The Project Site, including the proposed location for the street-level terminal building was characterized primarily by urban land uses that provided limited habitat for terrestrial plants and animals—mostly office space and commercial, residential, cultural, and institutional uses. The nine-story (approximately 100 feet) Northeast Plaza Building (5 WTC) was located in the northeast corner where the street-level terminal building has been proposed as part of the Preferred Alternative. Open space areas within and adjacent to the Project Site provided limited habitat for terrestrial biota. The largest open space area within the Project Site in the vicinity of the proposed location for the street-level terminal building (Church Street, between Fulton and Dey streets) was the nearly 4-acre Austin J. Tobin Plaza that was located at the center of the WTC complex (Figure 13-1). The plaza had limited access from adjacent streets, was isolated from other open spaces around the WTC complex, and was sparsely vegetated. Other open space areas on the Project Site included landscaped areas along Church, Vesey, and Liberty Streets that contained planters, and a 1.06-acre plaza at 130 Liberty Street south of the main WTC complex that contained planters with trees and a large fountain. One Liberty Plaza, a 0.64 acre plaza to the southeast of the Project Site, also had planters and trees.

The natural resources found within the open space areas of the Project Site were characteristic of those found in the urban landscape: shade trees, planters with ornamental vegetation, and wildlife tolerant of urban conditions such as house sparrows, European starlings, pigeons, and rodents such as squirrels. Breeding birds documented in western lower Manhattan (including the Project Site) in the early 1980s by the NYSDEC Breeding Bird Atlas (census block 5750B) include: pigeon (*Columba livia*), mourning dove (*Zenaida macroura*), chimney swift (*Chaetura pelagica*), blue jay (*Cyanocitta cristata*), American robin (*Turdus migratorius*), northern mockingbird (*Mimus polyglottus*), European starling (*Sturnus vulgaris*), common grackle (*Quiscalus quiscula*), house finch (*Carpodacus mexicanus*), and house sparrow (*Passer domesticus*). The peregrine falcon (*Falco peregrinus*), which is listed by the State of New York as endangered, is known to occur in the vicinity of the Project Site.

Migratory birds move through New York City during spring and autumn migrations between tropical Central and South American overwintering grounds and North American nesting grounds, and were known to use the limited habitat within the Project Site and surrounding areas as a resting habitat. Peak migration occurs between March and May in spring, and August and October in autumn. Examples of songbirds and other birds reported in bird strike data compiled by the New York City Audubon Society (NYCAS) at the WTC complex during spring and autumn migratory periods pre-September 11, 2001, include: white-throated sparrow (*Zonotrichia albicollis*), common yellowthroat (*Geothlypis trichas*), ovenbird (*Seiurus aurocapillus*), dark-eyed junco (*Junco hyemalis*), American woodcock (*Scolopax minor*), song sparrow (*Melospiza melodia*), swamp sparrow (*Melospiza georgiana*), gray catbird (*Dumetella carolinensis*), black-throated blue warbler (*Dendroica caeruluscens*), and black-and-white warbler (*Mniotilta varia*). Warbler and sparrow species constituted the majority of the species recorded during the NYCAS's 1997–2001 Project Safe Flight Program, as dead or injured from collisions with WTC complex buildings. No threatened, endangered, or special concern species were found dead or injured in the area during the program (NYCAS 2003).

FLOODPLAINS

Figure 13-2 indicates the location of the 100-year and 500-year floodplains within the Project Site. Prior to the September 11, 2001 attacks, a portion of the hotel (3 WTC), the western portion of Tobin Plaza, the pedestrian tunnel to the World Financial Center (WFC), and the western portion of the WTC PATH Terminal platform and tracks, were located within the 100-year floodplain. The pedestrian tunnel and WTC PATH Terminal platform and tracks were below grade. Flood protection measures in compliance with state and federal requirements were intact and operational. These included the bathtub walls and concrete slab to prevent ground water inundation, and the use of sump pumps.

WATER QUALITY AND AQUATIC RESOURCES

The WTC cooling water intake and outfalls, which were also used for the WTC PATH Terminal, are located at Battery Park City, in the lower Hudson River Estuary. The lower Hudson River Estuary is part of the New York/New Jersey Harbor Estuary, which also includes upper and lower New York Harbor, Arthur Kill, Kill Van Kull, East River, Raritan Bay, and Jamaica Bay. The Hudson River is the largest single freshwater input to this coastal plain estuary. The Hudson River Estuary extends approximately 150 miles upriver from the Battery to the Federal Dam at Troy, New York. The river gradient within the Estuary is very low, rising only 5 feet, and is tidally influenced throughout this extent (Moran and Limburg 1986).

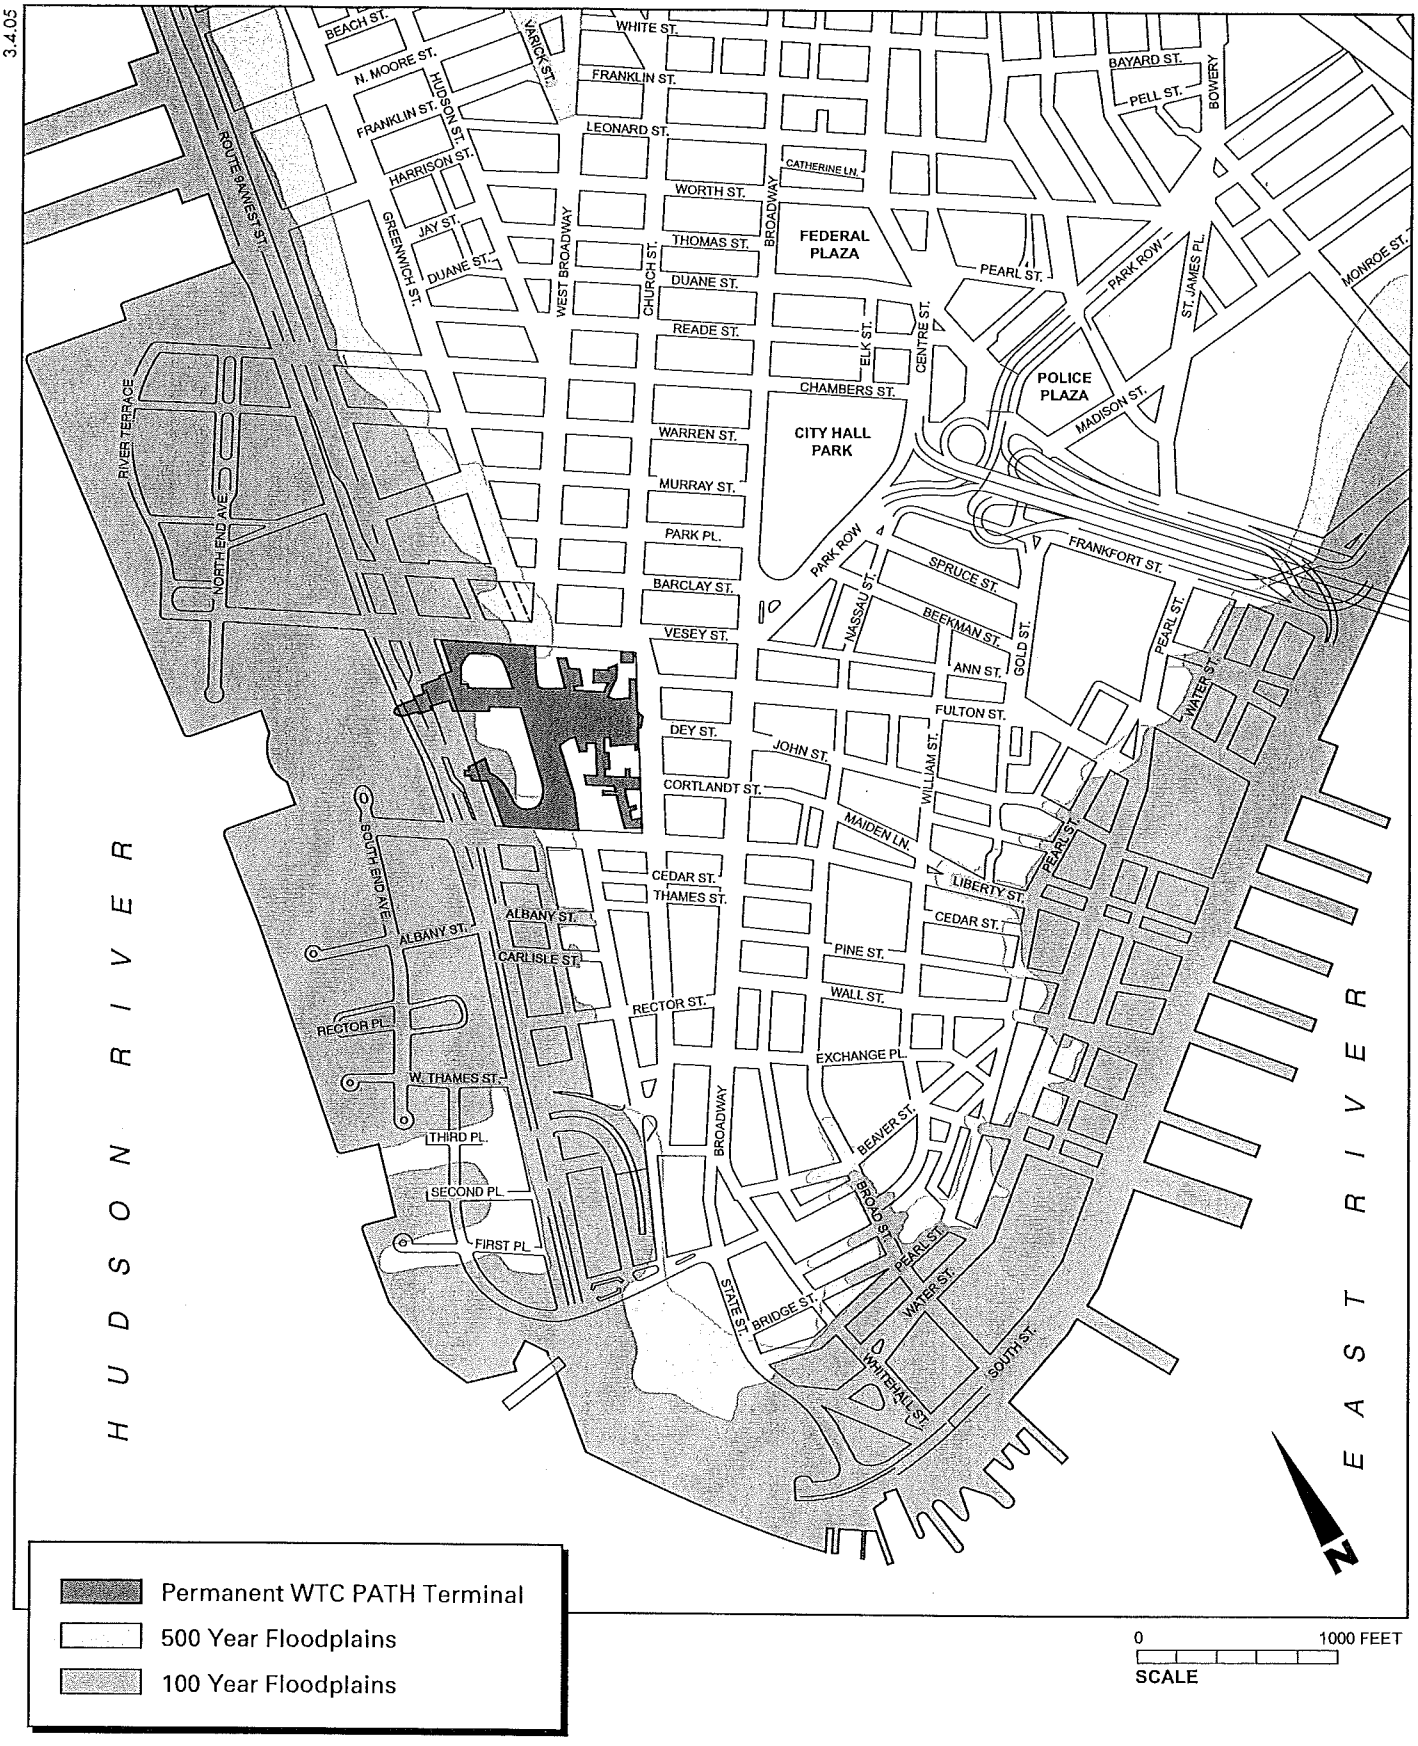
Figure 13-1

Austin J. Tobin Plaza Pre-September 11, 2001



PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure 13-2
Floodplains

Salt water and tides dominate the flows and physical characteristics of the lower Hudson River Estuary. The estuary receives salt water from Upper New York Harbor during the flood phase of a tidal cycle, discharging less saline water to the Upper Harbor during the ebb phase (Moran and Limburg 1986). The Estuary is partially stratified; more saline waters are generally found toward the bottom and fresher waters toward the surface. However, under low freshwater flow conditions the fresh and saline waters are generally well mixed (Busby and Darmer 1970).

Water Quality

The City of New York has monitored New York Harbor water quality with an annual survey (Harbor Survey) for over 90 years. NYCDEP conducts the survey by collecting water samples at stations in four designated regions: Inner Harbor Area, Upper East River-Western Long Island Sound, Lower New York Bay-Raritan Bay, and Jamaica Bay (NYCDEP 2002). The WTC cooling water intake and outfalls are located in the Inner Harbor Area, which includes the lower Hudson River to the Harlem River, the East River to the Battery, the Kill Van Kull and Arthur Kill, and the Upper New York Harbor south to the Narrows.

Major improvements to water quality of the Lower Hudson River Estuary, indicated by lower fecal coliform bacteria concentrations and higher dissolved oxygen concentrations, occurred in the mid- to late-1980s. These improvements were primarily due to regional decreases in municipal and industrial discharges that occurred through the construction and upgrading of water pollution control plants (NYCDEP 1998 and 2003). While water quality continued to improve until the early 1990s, since that time improvements have been relatively small (NYCDEP 2003). Therefore, the water quality conditions described for pre-September 11, 2001 would be expected to be similar to the post-September 11, 2001 conditions. Additionally, because the operation of the WTC cooling water intake and outfalls was in compliance with the 1999 SPDES permit conditions (EPA 2003), discharges of cooling water through the WTC outfalls would not be expected to have affected water quality.

Recent survey data from the Harbor Survey station closest to the project area, mid-stream off of Pier A just to the south, indicate that the water quality in this part of the lower Hudson River is good. Water quality usually meets the dissolved oxygen, fecal coliform, total coliform, and other water quality standards for Class I saline surface waters. NYSDEC defines Class I waters as saline surface waters that are best used for secondary contact recreation and fishing, and are suitable for fish propagation and survival. Temporary increases in fecal coliform concentrations may occur during wet weather due to increased fecal coliform loadings following a rain event. Dissolved oxygen concentrations in bottom waters occasionally fall below 4 mg/L standard for Class I waters. Secchi transparency measurements, which are used to test water clarity, indicate periodic reduced water transparency (i.e., increased cloudiness) in this area.

Sediment

Typical of any urban watershed, New York Harbor Estuary sediments are contaminated from a history of industrial uses in the area. Contaminants found throughout the New York Harbor Estuary include pesticides (i.e., chlordane and DDT), metals (i.e., mercury, cadmium, lead, and copper), polychlorinated biphenyls (PCBs), and various polycyclic aromatic hydrocarbons (Rohmann and Lilienthal 1987). Adams et al. (1998) found the mean sediment contaminant concentration for 50 of 59 chemicals measured in sediment samples from the New York/New Jersey Harbor Estuary to be statistically higher than other coastal areas on the East Coast. While the sediments of the New York Harbor Estuary are contaminated, the levels of most sediment

contaminants have decreased on average by an order of magnitude over the past 30 years (Steinberg et al. 2002).

Aquatic Biota

The New York/New Jersey Harbor Estuary, including the lower Hudson River, supports a diverse and productive aquatic community of over 100 species of finfish, more than 100 invertebrate species, and a variety of phytoplankton and zooplankton. The following sections provide a brief description of the aquatic biota found in the Harbor Estuary, focusing on the lower Hudson River. While the following description is based on studies that have been conducted in this area from the 1980s through the present, the aquatic community is generally considered to have been stable over the this period, although there is considerable annual and seasonal variability, and the description of existing conditions presented below would apply to the pre- and post-September 11, 2001 conditions.

Phytoplankton are microscopic plants whose movements within the system are largely governed by prevailing tides and currents. Light penetration, turbidity and nutrient concentrations are important factors in determining phytoplankton productivity and biomass. Diatoms such as *Skeletonema costatum* and *Thalassiosira* spp. generally dominate the phytoplankton community, with lesser contributions from dinoflagellates and green algae (Brosnan and O'Shea 1995). While nutrient concentrations in most areas of New York Harbor are very high, low light penetration has often precluded the occurrence of phytoplankton blooms. Limited light penetration also restricts the distribution of submerged aquatic vegetation in the Harbor. Benthic macroalgae are large multicellular algae that are important primary producers in the aquatic environment. Species of macroalgae that occur in the Harbor Estuary include sea lettuce, green fleece, and brown algae (*Fucus* spp.) (PBS&J 1998).

Zooplankton are an integral component of aquatic food webs—they are primary grazers on phytoplankton and detritus material, and are themselves used by organisms of higher trophic levels as food. The higher-level consumers of zooplankton typically include forage fish, such as bay anchovy, as well as commercially and recreationally important species, such as striped bass and white perch during their early life stages. Crustacean taxa (copepods *Acartia tonsa, Acartia hudsonica, Eurytemora affinis*, and *Temora longicornis)* dominate the zooplankton community, with the dominant species changing with the season (Stepien et al. 1981, Lonsdale and Cosper 1994, Perlmutter 1971, Lauer 1971, Hazen and Sawyer 1983).

The major groups of benthic invertebrates collected in the estuary include aquatic earthworms (oligochaetes), segmented worms (polychaetes), snails (gastropods), bivalves, barnacles, cumaceans, amphipods, isopods, crabs, and shrimp (EEA 1988, EA Engineering Science and Technology 1990, Coastal 1987, and PBS&J 1998).

New York City is located at the convergence of several major river systems, all of which connect to the New York Bight portion of the Atlantic Ocean. This convergence has resulted in a mixture of habitats in the Harbor Estuary and lower Hudson River that support marine, estuarine, anadromous (fish that migrate up rivers from the sea to breed in freshwater), and catadromous fish (fish that live in freshwater but migrate to marine waters to breed).

According to Woodhead (1990), populations of numerically dominant fish within the Harbor Estuary (hogchoker, tomcod, winter flounder, white perch and striped bass) remain relatively stable from year to year. Studies at Pier 76 north of the WTC cooling water intake during the winter from 1982 to 1983 and 1988 and 1992, reported that the same four species of fish (striped bass, white perch, winter flounder, and Atlantic tomcod) comprised about 88 to 90 percent of the

fishes collected (EEA 1988; Stoecker et al. 1992). Although there are differences in abundance of fish among years and seasons, field investigations conducted by Able et al. (1995) in the Lower Hudson River (Piers 40 and 76) in 1993 and 1994 found that the composition and distribution of fish were similar to those reported in previous studies such as Beebe and Savidge (1988). Nine species comprised nearly 95 percent of the total number of fish collected, with juvenile striped bass the most abundant followed by Atlantic tomcod, American eel, seaboard goby, cunner, northern pipefish, naked goby, winter flounder, and tautog (Able et al. 1995).

Researchers have also found substantial differences in the use of interpier, underpier and pile field areas by fish within the lower Hudson Estuary (EEA 1988, EA Engineering, Science and Technology 1990, Able et al. 1995, Able et al. 1998, Able et al. 1999, and Duffy-Anderson and Able 1999). In general, abundance and variety of fish species was greater in open water habitats and pile fields than under platforms, and for juvenile fish, habitat quality under platforms greater than 20,000 square meters (5 acres) appeared to be poor (Able et al. 1998).

ESSENTIAL FISH HABITAT (EFH)

An essential fish habitat (EFH) assessment was prepared for the *WTC Memorial and Redevelopment Plan GEIS* to identify EFH designations for the Lower Hudson River Estuary in the vicinity of the WTC intake and outfalls, and potential impacts from the operation of the intake and outfalls. This area has been identified as EFH for 15 species of fish: red hake (larvae, juveniles, and adults), winter flounder (eggs, larvae, juveniles, adults, and spawning), windowpane (eggs, larvae, juveniles, and adults), Atlantic herring (larvae, juveniles, and adults), bluefish (juveniles and adults), Atlantic butterfish (larvae, juveniles, and adults), Atlantic mackerel (juveniles and adults), summer flounder (larvae, juveniles, and adults), scup (eggs, larvae, and juveniles), black sea bass (juveniles and adults), king mackerel (eggs, larvae, juveniles, and adults), Spanish mackerel (eggs, larvae, juveniles, and adults), cobia (eggs, larvae, juveniles, and adults), sand tiger shark (larvae), and sandbar shark (larvae and adults).

ENDANGERED, THREATENED, AND SPECIAL CONCERN SPECIES

Requests for information on rare, threatened or endangered species within the immediate vicinity of Project Site were submitted to USFWS, NMFS, and the NYSDEC Natural Heritage Program (NYNHP). Appendix G presents the responses from these agencies. USFWS indicated that no federally listed or proposed endangered or threatened species were currently known to exist in the vicinity of the Project Site (Stilwell 2003). NYNHP also indicated that they had no records of known occurrences of rare or state-listed animals or plants, substantial natural communities, or other substantial habitats, on or in the immediate vicinity of the Project Site (Conrad 2003). NMFS indicated that there may be seasonal use of the Hudson River by shortnose sturgeon (*Acipenser brevirostrum*), and occasional transient use by four species of marine turtle: loggerhead (*Caretta caretta*), green (*Chelonia mydas*), Kemp's ridley (*Lepidochelys kempii*), and leatherback (*Dermochelys coriacea*) (Rusanowsky 2003). Because the information supplied by these federal and state resource agencies is based upon current and past records and habitat and water quality conditions have not changed substantially since 1990, the species identified apply to the pre-September 11, 2001 and post-September 11, 2001 conditions.

Shortnose sturgeon (New York State and federally listed endangered) have the potential to occur within the Lower Hudson River Estuary as transient individuals to and from upriver spawning and nursery grounds and overwintering areas. These fish spawn, develop, and overwinter well upriver, and prefer colder, deeper waters. Out of the more than 1,000 trawls taken in the

Westway study in both the Hudson and East River, only one shortnose sturgeon was collected, in the deep water habitat, near the Peekskill-Haverstraw section of the Hudson River. Long-term Hudson River monitoring data, collected by the New York Utilities and others since the 1970s, have also indicated that shortnose sturgeon inhabit deep-water habitats, and occur in greatest abundance north of the Tappan Zee Bridge.

The four species of marine turtles, all state and federally listed, can occur in New York Harbor. Juvenile Kemps ridley and large loggerhead turtles enter the New York Harbor and bays in the summer and fall. The other two species, green sea turtle and leatherback sea turtle, are usually restricted to the higher salinity areas of the Harbor (USFWS 1997). In general, however, these four turtle species mostly inhabit Long Island Sound and Peconic and Southern Bays. They neither nest in the New York Harbor Estuary, nor reside there year-round (Morreale and Standora 1995). Turtles leaving Long Island Sound for the winter usually do so by heading east to the Atlantic Ocean before turning south (Standora et al. 1990). It is unlikely that these turtle species would occur in the lower Hudson River except as occasional transients.

While not identified by NYNHP as occurring in the vicinity of the proposed location for the Preferred Alternative (Conrad 2003), the peregrine falcon (*Falco peregrinus*), which is listed by the State of New York as endangered, was identified by the NYNHP as occurring in the vicinity of the elements of the WTC Memorial and Redevelopment Plan (Houle 2003). Preferred habitats for this raptor include open areas such as tundra, savannah, seacoasts, and open forests, and tall buildings. Peregrine falcons feed primarily on birds that they capture in the air. Nests are built on high ledges between 50 to 200 feet off the ground. Young falcons may stay in the vicinity of the nest for about six weeks after fledging, developing their flying and hunting skills. Peregrine falcons mate for life and generally return to the same nesting territory each year. The number of breeding pairs in New York has increased steadily since the first peregrines returned to nest in New York City in 1983 (NYSDEC 2003).

CHANGES IN THE AFFECTED ENVIRONMENT SINCE SEPTEMBER 11, 2001

TERRESTRIAL RESOURCES

The limited natural resources within the Project Site were destroyed as a result of the terrorist attacks and subsequent during recovery efforts. The original WTC PATH Terminal sustained extensive damage. The Project Site is currently vacant except for the temporary WTC PATH station and the No. 1 and 9 subway line crossing the site. Construction of the temporary WTC PATH station began in July 2002 and was opened on November 23, 2003. The temporary station stands at the site of the original terminal and comprises five levels—platform, mezzanine, 1 and 9 underpass, concourse, and street level. The street level portion of the station includes an entry plaza and canopy along the west side of Church Street near Fulton Street that has little landscaping. The temporary WTC PATH station mezzanine, station platform, and rail tracks are located at the western portion of the Project Site.

The Project Site is fenced off except for the temporary WTC PATH station and a newly constructed sidewalk and viewing area on the west side of Church Street. All passengers must access and leave the temporary WTC PATH station at the street-level entrance at Church and Fulton Streets. Currently, terrestrial resources within the Project Site are limited to pioneering plant species that are capable of growing in denuded areas, and possibly occasional individual animals that are tolerant of extremely disturbed conditions. Some shade trees exist on the perimeter of the demolition area. Therefore, the Project Site and the surrounding area to be

developed as part of the WTC Memorial and Redevelopment Plan currently contain extremely limited habitat for wildlife, and would not likely be used as a stopover area by migratory birds.

FLOODPLAINS

The pedestrian tunnel leading from the WTC PATH Terminal to the WFC and the station platform and tracks were damaged as a result of the September 11, 2001 attacks. The platform and tracks were repaired as part of the temporary WTC PATH station, which was opened in November 2003. The pedestrian tunnel to the WFC remains closed. As was the case prior to September 11, 2001, the western portion of the platform and tracks for the temporary WTC PATH station are within the 100-year floodplain (Figure 13-2). Other elements of the WTC complex that were partially located within the floodplain on the Project Site prior to September 11, 2001, 3 WTC and Tobin Plaza, were removed as a result of the terrorist attacks and restoration efforts. In addition to the flood protection measures that were in place pre-September 11, 2001, additional sump pumps have been installed to minimize water on the Project Site and sandbags would be manually placed on existing truck ramps in the event of the 100-year flood.

WATER QUALITY AND AQUATIC RESOURCES

As discussed previously, because the major infrastructure improvements were completed by 1990, water quality has remained fairly consistent since the early 1990s. Therefore, the post-September 11, 2001 water quality is not expected to have changed from that described previously under the pre-September 11, 2001 condition.

Because the dominant fish in the lower Hudson River and the New York/New Jersey Harbor Estuary have remained fairly stable since the late 1980s, when the majority of the substantial infrastructure improvements occurred in New York City (Woodhead 1990, ASA 2003), the aquatic biota for the lower Hudson River described under the pre-September 11, 2001 conditions scenario would also represent the post-September 11, 2001 conditions. No changes would have occurred other than the shut-down of the WTC cooling water intake. It is not expected that the shut-down of the WTC intake on September 11, 2001 would have affected the species reported to be present in the Lower Hudson River Estuary.

Sampling programs conducted in the Lower Hudson River Estuary post-September 11, 2001 have collected similar fish species to those conducted pre-September 11, 2001. Sampling conducted within the Hudson River Park to track changes to the aquatic community over time after the post-September 11, 2001 emergency dredging that occurred near Pier 25 (Meixler et al. 2003) recorded 41 fish species within the park. The most abundant species were bay anchovy (87 percent), striped bass (4 percent), Atlantic herring (4 percent), and alewife (2 percent). Bay anchovy adults are known to occur in high numbers in the Lower Hudson River Estuary in the summer, and are generally absent from the estuary in the winter (Woodhead et al. 1992). Sampling conducted for the Hudson River Utilities (ASA 2003) in the Lower Hudson River Estuary has also found that the same dominant fish species have been collected in the monitoring program since the mid-1980s, although variations do occur from year to year. Sampling conducted by the ACE from 2002 to 2003 (LMS 2003) found the most common fish collected in the Upper Bay to be striped bass (December through January), winter flounder (February), windowpane (February through March), spotted hake (April) and bay anchovy (May through June). Atlantic menhaden, bay anchovy, windowpane, and winter flounder, species that spawn in the Harbor, occurred in high densities during their spawning period (March through July).

ESSENTIAL FISH HABITAT (EFH)

As identified in the World Trade Center Memorial and Redevelopment Plan FGEIS, no substantial changes in the EFH of the Lower Hudson River Estuary have occurred since September 11, 2001.

ENDANGERED, THREATENED, AND SPECIAL CONCERN SPECIES

No changes to potential endangered, threatened, or special concern species in the lower Hudson River are anticipated to have occurred since the events of September 11, 2001.

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

CONSTRUCTION PERIOD (2006)

FUTURE COMMON TO ALL ALTERNATIVES

Terrestrial Resources

As discussed in Chapter 4, "Land Use, Neighborhood Character, and Public Policy," several projects are planned for the Project Site and immediate vicinity during the construction period for the Preferred Alternative. Noise, vehicular traffic, and other human activity associated with these projects have the potential to affect some wildlife. However, individuals using the limited resources available on the site would be expected to be tolerant of urban conditions and would not likely be affected by construction activities.

Floodplains

As described previously, certain elements of the WTC Memorial and Redevelopment Plan located on the Project Site would be constructed during the construction period for the Preferred Alternative. Of these, only the Memorial and Liberty Park North would be located within the floodplain portion of the Project Site. Both of these elements would include pervious and impervious surfaces and appropriate drainage systems. Flood protection measures present prior to September 11, 2001 would remain and continue to control flooding. In addition, all areas developed within the Project Site as part of the WTC Memorial and Redevelopment Plan would be constructed with appropriate stormwater management measures. Appropriate stormwater management measures would also be implemented during the reconstruction of the Route 9A. Therefore, these projects would not be expected to adversely affect the water retention and flood control characteristics within or adjacent to the Project Site.

Water Quality and Aquatic Resources

Potential impacts to water quality and aquatic resources associated with the projects described above would be addressed in separate environmental reviews and permitting, as necessary. Any stormwater discharges would be managed with approved Stormwater Pollution Prevention Plans (SWPPPs) and established regulatory programs to minimize potential impacts to water quality and aquatic resources.

There are proposed and ongoing projects aimed at improving water quality and aquatic resources in the New York/New Jersey Harbor Estuary, several of which are sponsored by PANYNJ, which have the potential to result in water quality and aquatic habitat improvements in the Lower Hudson River Estuary, where the WTC cooling water intake is located. These projects

are independent of the Preferred Alternative. Improvements that result from these projects would occur without the Preferred Alternative and are expected to continue through the construction period.

Several of the future water quality improvement efforts in the Lower Hudson River Estuary will be coordinated by the New York/New Jersey Harbor Estuary Program (HEP). The Final Comprehensive Conservation and Management Plan (NY/NJ HEP 1996) for the HEP included a number of goals to improve water quality and aquatic resources in the area. The plan outlines objectives for the management of toxic contamination, dredged material, pathogenic contamination, floatable debris, nutrients and organic enrichment, and rainfall-induced discharges. The HEP Habitat Workgroup has developed watershed-based priorities for identifying acquisition, protection, and restoration sites for the preservation and enhancement of tidal wetlands that will provide improved habitat for fish and macroinvertebrates as well as birds, mammals, and reptiles that depend on these habitats. No NY/NJ HEP Acquisition and Restoration Sites have been identified near the WTC intake and outfalls. NY/NJ HEP Acquisition and Restoration Sites in closest proximity to the lower Hudson River are listed below. These NY/NJ HEP will occur independent of the Preferred Alternative.

- Liberty State Park—Located in the Upper New York Bay it has been identified for restoration, including permanent protection of natural areas, enhancement of emergent habitat, and restoration of oyster beds;
- Western Manhattan Island Parks—Several parks on the western shore of Manhattan (Riverdale Park, Inwood Park, Fort Tryon, Fort Washington Park, and Riverside Park) have been selected as priority restoration sites and are targeted for non-point source pollution reduction measures in addition to habitat restoration;
- Spuyten Duyvil—Located on the Harlem River near its confluence with the Hudson River, this park was chosen as a priority restoration site for salt marsh restoration; and
- Bush Terminal—Located in Upper New York Bay on the Brooklyn shoreline, it was chosen as a priority restoration site for salt marsh restoration.

The Contamination Assessment and Reduction Project, sponsored by PANYNJ, is a component of HEP focused on understanding the fate and transport of contaminants discharged to the estuary, and using this information to develop measures that may be necessary to reduce sediment contamination. The principal chemicals of concern include dioxins/furans, PCBs, polyaromatic hydrocarbons (PAHs), metals (mercury, cadmium, and lead), and pesticides (dieldrin and chlordane). Continued research and monitoring programs are anticipated to play a role in the development of future management strategies for Harbor sediments (NY/NJ HEP undated, ACE 1999).

The Hudson-Raritan Estuary Ecosystem Restoration Project is a cooperative project being led by the ACE that was funded by a U.S. House of Representatives Resolution on 15 April 1999. PANYNJ is a co-sponsor of this project. Other agencies involved in this project include EPA, USFWS, NOAA, National Resource Conservation Service, New Jersey Department of Environmental Protection (NJDEP), New Jersey Department of Transportation (Office of Maritime Resources), NYSDEC, NYSDOS, NYCDEP, New York City Parks and Recreation, and New Jersey Meadowlands Commission. The focus of the study is to identify the actions needed to restore the Hudson-Raritan Estuary and develop a plan for their implementation. The study area for the program includes all the waters of New York and New Jersey Harbor and the tidally influenced portions of all rivers and streams that empty into the Harbor and ecologically

influence the Harbor. The program will identify measures and plans to restore natural areas within the estuary and enhance their ecological value, and address habitat fragmentation, and past restoration and mitigation efforts that were piecemeal in nature. Thirteen initial representative restoration sites in New York and New Jersey have been targeted as the first sites for inclusion as potential restoration projects for feasibility level analysis. It is anticipated that expedited restoration of these representative restoration sites will provide substantial immediate value to the ecosystem. None of these sites occur in the vicinity of the WTC intake and outfalls. Therefore, actions taken by the Hudson-Raritan Estuary Ecosystem Restoration Project with respect to these sites would occur with or without the Preferred Alternative.

The New York sites include:

- Alley Pond Park (bordering western Long Island Sound),
- Old Place Creek (a tributary to the Arthur Kill),
- Newtown Creek (a tributary to the lower East River),
- Brookville Creek (a tributary to Jamaica Bay),
- Dreier Offerman Park (bordering Coney Island Creek near The Narrows),
- Sherman Creek (a tributary to the Harlem River),
- Pelham Lagoon and Turtle Cove (a tributary to western Long Island Sound), and
- Tallapoosa (a tributary to western Long Island Sound).

The New Jersey sites include:

- Leonardo (bordering Raritan Bay),
- Rahway River (a tributary to Raritan Bay),
- Marquis Creek (a tributary to Raritan Bay),
- Liberty State Park (on western Upper New York Bay), and
- Kearny Marsh (with tributaries that drain to Newark Bay).

In addition to the 13 representative sites, three spin-off sites have been identified. These are restoration sites being evaluated in parallel to the representative sites. They include the Lower Passaic River and Hackensack Meadowlands in New Jersey, and Gowanus Canal in New York (a tributary to the Upper New York Bay).

The Comprehensive Port Improvement Plan, sponsored by PANYNJ, is a multi-agency plan for implementing economic development and environment improvement decisions for PANYNJ. Among the priority objectives for the Plan are the identification and protection of significant habitats, the investigation of innovative best management practices for reduction of non-point sources of water pollutants, and the incorporation of green technologies in port improvement projects.

NYSDEC and NJDEP, in coordination with the IEC, will continue to develop total maximum daily loads and to identify priority waterbodies in bi-annual 305(b) reports to EPA. Total maximum daily loads, once implemented, will reduce the daily inputs of various contaminants in an effort to improve water quality. New York State provided $255 million to implement wastewater improvements, nonpoint source abatement and aquatic habitat restoration projects in 1998. The State intends to continue water quality improvement projects in the Harbor for the foreseeable future.

EPA's National Combined Sewer Overflow (CSO) Strategy of 1989 requires states to eliminate dry weather overflows of sewers, meet federal and state water quality standards for wastewater discharges, and minimize impacts on water quality, plant and animal life, and human health.

CSOs are the largest single source of pollutants and pathogens to the New York Harbor. NYCDEP has taken several steps in recent years to mitigate discharges from CSOs, which, in combination with improvements that have been made to water pollution control plants (WPCP), are expected to result in future improvement in coliform, dissolved oxygen and floatables levels in the New York Harbor area. The Multi-Year Intended Use Plan of the NYC Municipal Water Financing Authority has identified several CSO improvement and abatement projects, which will be completed between 2003 and 2010. NYCDEP plans to increase the track-down and control of pollutants of concern including mercury, polychlorinated biphenyls, and solvents.

NO ACTION ALTERNATIVE

Terrestrial Resources

Under the No Action Alternative, the temporary WTC PATH station will remain operable and construction activity associated with the WTC Memorial and Redevelopment Plan will occur on the WTC site. The temporary WTC PATH station includes an entry plaza and canopy along the west side of Church Street near Fulton Street that has little landscaping. The temporary WTC PATH station is not constructed of materials such as reflective glass with the potential to affect wildlife. Therefore, the continued use of the station will not be expected to result in adverse impacts to wildlife during the construction period.

Floodplains

Under the No Action Alternative, the temporary WTC PATH station would continue to exist on the Project Site. All flood protection measures currently present on the Project Site would be maintained. The continued use of the temporary WTC PATH station would not be expected to adversely affect the floodplain.

Water Quality and Aquatic Resources

Under the No Action Alternative, the temporary WTC station would continue to exist. No adverse impacts to water quality or aquatic resources would be expected to occur due to stormwater discharge. The temporary WTC station is not heated or cooled and therefore would not require the withdrawal of Hudson River water.

PREFERRED ALTERNATIVE

Terrestrial Resources

The majority of the Preferred Alternative would be built underground in the bathtub, including the PATH tubes, tracks, platform level, mezzanine/fare-zone level, sub-grade connections to adjacent streets, New York City Transit subways, and on- and off-site developments. The street-level terminal building would be constructed in the northeast corner of the Project Site at the western side of Church Street between Dey and Fulton Streets.

The use of bright lighting associated with nighttime construction has the potential to attract some birds and may result in collisions with construction equipment. The above-grade portion of the temporary WTC PATH station, the steel beam in cross form, and the remnants of the Vesey Street stairway to plaza level are the only structures on the Project Site above street level. The temporary station, however, does not contain walls or reflective glass surfaces, and would not be expected to cause bird strikes. Because of the lack of reflective surfaces, vegetation, and tall

illuminated structures at the Project Site that might attract birds during the construction period, it is unlikely that bird collisions would occur.

Noise associated with construction activities would have the potential to deter some wildlife species from using the site. As noted above, these effects would not likely be adverse, given that the Preferred Alternative is located in a densely urban area that is populated by urban-tolerant species. Therefore, adverse impacts to terrestrial resources would not be expected to occur during construction of the Preferred Alternative.

Floodplains

Elements of the Project located in the 100-year floodplain, as delineated by FEMA, include small portions of the platform level, mezzanine level, and the east–west concourse (see Figure 13-2). All of these areas are below grade and would not adversely impact the floodplain. In addition, flood protection measures currently on the Project Site would be repaired or maintained to control the introduction of ground water and control stormwater during construction. The street-level Terminal Building would not be located within the floodplain. Construction of the Preferred Alternative would not result in adverse impacts upon the floodplain due to the grades to be reconstructed on the Project Site.

Water Quality and Aquatic Resources

During construction, stormwater management would be in compliance with the approved SWPPP. Stormwater generated within the Project Site would not be discharged directly to surface waters, but would be directed to the municipal combined sewer system, as described in Chapter 11, "Infrastructure and Energy." Groundwater recovered during dewatering activities and stormwater generated by PATH's east–west connection beneath Route 9A would be treated by NYSDOT or PANYNJ, depending upon which agency is charged with its construction (see Chapter 2, "Project Alternatives"), prior to discharge to the city's combined sewer system. Implementation of best management practices for erosion and sediment control and other measures of the SWPPP would minimize potential impacts to the municipal combined sewer system. Construction activities are not expected to substantially increase stormwater volume.

Essential Fish Habitat Assessment

Because no in-water construction activities would be required as part of this alternative, no physical alteration would occur to EFH in the vicinity of the WTC site during the construction period. There would be no need for dredging or any extensive bottom disturbing actions that could negatively affect fish habitat. In addition, no adverse impacts to water quality are anticipated from construction of the Preferred Alternative. Therefore, no adverse impacts to EFH would be expected to occur due to construction of the Preferred Alternative.

Endangered, Threatened, and Special Concern Species

As indicated by USFWS and NYNHP, no endangered, threatened, or special concern species or significant habitats are known to occur within the Project Site.

NMFS (Rusanowsky 2003) indicated that shortnose sturgeon and four marine turtle species may occur seasonally in the Hudson River. Because no in-water work would be done during construction of the project, and no stormwater generated at the project site would be discharged directly to surface waters during construction, no adverse impacts would be expected to occur to these species during the construction period of the Preferred Alternative.

OPENING YEAR (2009)

FUTURE COMMON TO ALL ALTERNATIVES

Terrestrial Resources

It is expected that all proposed open space elements of the WTC Memorial and Redevelopment Plan would be completed by 2009. The planned parks—at 7 WTC and within the WTC site—would include shade trees and other plantings. These open space areas would have the potential to provide some limited terrestrial habitat for resident birds and other urban-tolerant wildlife such as squirrels and resting habitat for migratory songbirds.

The World Trade Center Memorial and Redevelopment Plan and the Route 9A Project, which are independent from the Preferred Alternative, may introduce additional habitats within the study area. Open space areas planned on the WTC site and within the median of Route 9A could total approximately 7 acres. The Route 9A project will also include upgrades to the existing stormwater drainage system and a bikeway/walkway along the west side of the highway and features landscaping and planters.

Construction activities associated with the elements of the WTC Memorial and Redevelopment Plan planned for completion in 2015 (Towers 2, 3, 4, and 5, and hotel) would be ongoing. Noise associated with construction activities would have the potential to deter some wildlife species from using the habitats available in open space areas near the Project Site. However, most wildlife with the potential to use these areas are tolerant of urban conditions.

Brightly illuminated buildings and towers can attract birds (Schmidt-Keonig 1979) and have the potential to result in bird strikes at night during spring and autumn migratory periods. Potential impacts to birds due to collisions with buildings proposed as part of the WTC Memorial and Redevelopment Plan, and measures to reduce the potential for bird strikes, would be evaluated as part of the separate environmental review for the WTC Memorial and Redevelopment Plan.

Floodplains

By 2009, it is assumed that several of the elements of the WTC Memorial and Redevelopment Plan project would be complete, including the open space areas, Memorial, museum and cultural facilities, retail, and some office space. The WTC Memorial and Redevelopment Plan project is being addressed under a separate environmental review process. However, as discussed previously for the construction year, adverse impacts to the floodplain due to changes to the water retention and flood control characteristics of the Project Site would not be expected to occur from WTC Memorial and Redevelopment Plan project.

Water Quality and Aquatic Resources

As described above for the No Action Alternative during the construction period, proposed and ongoing projects aimed at improving water quality and aquatic habitat in the New York/New Jersey Harbor Estuary have the potential to result in water quality and aquatic habitat improvements in the Lower Hudson River Estuary. These projects are independent of the Project Alternatives. Improvements that result from these projects would occur with or without the Project Alternatives and are expected to continue through the opening year.

Implementation of approved SWPPPs would minimize stormwater impacts of the various development projects discussed previously that would be expected to occur as part of the WTC Memorial and Redevelopment Plan on and in the vicinity of the Project Site. By 2009 some

portions of these projects would be operational. Stormwater would be discharged to the combined sewer system and would not be discharged directly to surface waters.

The heated effluent discharged through the existing WTC cooling water system outfalls as part of the cooling system for the elements of the WTC Memorial and Redevelopment Plan completed in the opening year (2009) would be expected to meet the thermal criteria developed by NYSDEC and specified in 6 NYCRR Part 704 and the thermal criteria and monitoring requirements specified in PANYNJ's 1999 SPDES permit (Table 13-1). Conditions issued in the 1999 SPDES permit were developed by NYSDEC so that the WTC thermal effluent would be in compliance with surface water standard for Use I saline surface waters. Compliance with the thermal criteria specified in 6 NYCRR Part 704 and the permitting conditions would be considered protective of the designated use of the Lower Hudson River Estuary, including fish survival and reproduction. An Essential Fish Habitat (EFH) Assessment was prepared for the Lower Hudson River Estuary as part of the World Trade Center Memorial and Redevelopment Plan Final Generic Environmental Impact Statement (FGEIS). The full text of the EFH appears in Appendix I of the FGEIS, which is available at www.renewnyc.com.

Table 13-1
World Trade Center Cooling Water Outfall Discharge Limitations

Parameter	Discharge Limitations			Minimum Monitoring Frequency
	Daily Average	Daily Max	Units	
Flow	Monitor	Monitor	MGD	continuous
Discharge Temperature	Monitor	91	°F	continuous
Intake-Discharge Temperature Difference	Monitor	17	°F	daily
Total Residual Chlorine[1]	Monitor	0.2	mg/L	3 times per week
pH[2]	Monitor	Monitor	SU	2 times per month

Notes:
[1] Total residual chlorine shall not be discharged more than two hours per unit per day. There shall not be simultaneous chlorination of separable portions of a single unit more than one unit at one time.
[2] The intake pH range shall not be extended more than 0.1 pH unit.
Other Limitations:
Intake velocity at each fixed and/or traveling screen and at the first set of bar racks shall not exceed 1.8 fps.
Only one outfall may be operated at a time. Simultaneous use of Outfalls 001 and 002 is not allowed.
Source: NYSDEC State Pollution Discharge Elimination System Discharge Permit effective 05/01/99.

Potential adverse impacts to aquatic life from the operation of the WTC cooling water intake is being assessed under an independent action as part of the permit renewal process.

NO ACTION ALTERNATIVE

Terrestrial Resources

As discussed previously with respect to the construction period, because the temporary WTC PATH station is not constructed of materials such as reflective glass with the potential to affect wildlife, the continued use of the terminal would not be expected to result in adverse impacts to wildlife during the construction period.

Floodplains

Under the No Action Alternative the temporary WTC PATH station would remain and continue to operate on the Project Site. All flood protection measures currently present on the Project Site would be maintained. The continued use of the temporary WTC PATH station would not be expected to adversely affect the floodplain.

Water Quality and Aquatic Resources

Under the No Action Alternative, the temporary WTC station would continue to operate. No adverse impacts to water quality or aquatic resources would be expected to occur due to stormwater discharge. The temporary WTC station is not heated or cooled and therefore would not require withdrawal of Hudson River water.

PREFERRED ALTERNATIVE

Terrestrial Resources

Because most of the Preferred Alternative would be below street level, potential impacts to terrestrial resources would only be associated with the above-ground components that include the street-level terminal building, the headhouse adjacent to the Winter Garden, street-level entrances and emergency egress on the WTC site, and the ventilation structures in the median of Route 9A. In the opening year, landscaping around the street-level terminal building would provide limited wildlife habitat to wildlife species that tolerate urban conditions. Examples may include birds such as mourning doves, American robin, pigeon, sparrow, and chimney swifts, and small mammals such as squirrels, mice, and other rodents. The habitat provided by the landscaping around the street-level terminal building would contribute to the increased habitat resulting from the open space elements that would have been completed as part of the WTC Memorial and Redevelopment Plan. While the wildlife habitat resulting from the landscaping surrounding the street-level terminal would be small, it would be greater than what is currently available on the Project Site, and would be expected to be an enhancement compared to pre-September 11, 2001 conditions when the nine-story 5 WTC was present in this location.

The increased habitat that would be present as a result of this alternative and the proposed WTC Memorial and Redevelopment Plan would also have the potential to provide resting or stop-over habitat to migratory songbirds during the spring and autumn migrations, which is not present under current conditions. Because the open space area for the WTC Memorial and Redevelopment Plan and the Preferred Alternative in 2009 would be greater than what was present at the WTC complex pre-September 11, 2001, the resting habitat for migratory songbirds would also have the potential to increase compared to pre-September 11, 2001. However, this increase in bird habitat for resident and migratory species would have the potential to result in bird strikes on glass surfaces associated with the street-level terminal building.

As currently proposed, the street-level terminal would comprise an oblong glass and steel shell, the roof of which would contain two counterpoised glass wings that would rise more than 100 feet into the air and extend the length of the building (about 350 feet). The structure would allow natural light to illuminate the terminal concourse. The ceiling of the aboveground building may have the capacity to open up to the sky, between the two wing-like structures.

Potential impacts to resident and migratory birds associated with the Preferred Alternative would be greater than under the No Action Alternative because the above-ground portion of the temporary WTC PATH station is small and not constructed of materials that would encourage

strikes. Nighttime lighting of the building, and the proposed use of glass and steel for the street-level terminal would have the potential to result in the loss of migratory bird individuals. While the proposed design of the street-level terminal would not pose the same potential for bird strikes as the taller towers proposed for the WTC Memorial and Redevelopment Plan, it would still have the potential to attract migratory birds during the spring and fall migratory periods if brightly illuminated at night. However, measures could be considered for the Preferred Alternative that would reduce potential impacts to birds.

As discussed previously, brightly illuminated buildings and towers can attract birds (Schmidt-Keonig 1979). Nocturnal migrants, because they use primarily visual cues in the sky such as the stars and the setting sun (Moore 1987 in Ogden 1996) and topographical features on the ground (e.g., water surfaces and trees) to orient during flight, have the greatest potential to be fatally entrapped by lighted structures (Ogden 1996). Nocturnal migrants have been found to be attracted to and trapped by artificial light sources during bad weather conditions, and under good weather conditions with low clouds and no moon (Martin 1990 in Ogden 1996). Because most nocturnal migrants are normally active during the day outside the migratory period, their night vision is believed to provide poor resolution of detail, allowing them to detect only the grossest detail and a spatial resolution (Martin 1990 in Ogden 1996). Birds migrating at night have been found to enter artificially lit areas and then become trapped there by the light (Avery et al. 1976 in Ogden 1996), appearing to be disoriented. Nocturnal migrants have been observed flying around the light source to the point of exhaustion, colliding with the structure and each other (Ogden 1996).

Table 13-2 presents bird strike data compiled by the NYCAS from May 2001 to December 2003 (NYCAS 2004) for buildings near the Project Site. Data for buildings within the WTC complex are not presented because the buildings were not present through the entire data collection time frame. Birds reported in building collisions in Manhattan by NYCAS were primarily migratory songbirds, mostly warblers and sparrows, but also included representatives from other groups. During the 2001 through 2003 period the 15 bird species reported by NYCAS in highest number of bird strikes for all buildings included white-throated sparrow, common yellowthroat, dark-eyed junco, ovenbird, Nashville warbler, American woodcock, hermit thrush, ruby-crowned kinglet, blackpoll warbler, black-and-white warbler, yellow-bellied sapsucker, gray catbird, northern flicker, swamp sparrow, and golden-crowned kinglet. Although the lowest building near the Project Site with bird strikes reported for the 2001 to 2003 timeframe, the World Financial Center (WFC) Winter Garden had the highest number of reported bird strikes. The WFC Winter Garden possesses some characteristics similar to the general concept proposed for the street-level terminal building. It is a glass and metal atrium, about 125 feet high and 197 feet long. Indoor lighting is located toward the top.

Measures that have the potential to decrease bird strikes of nocturnal migrants include:

- Minimize amount of light emanating upward from the structure at night during the migratory season;
- Extinguish interior lights at night during the migratory season;
- Minimize exterior floodlighting during the migratory season; and
- Install perches on tall buildings so birds captured by nighttime lighting can rest (Ogden 1996).

Table 13-2
Bird Strike Data Compiled by NYCAS From May 2001 Through December 2003 for Buildings in the Vicinity of the Project Site

Building	Location	Height (feet)[1]	Bird Strikes
WFC Winter Garden	World Financial Center	125	83
2 WFC	NW corner West & Liberty Streets	645	66
4 WFC	SW corner Varick & Route 9A	500	40
3 WFC	200 Vesey Street	739	38
26 Federal Bldg	26 Federal Plaza	587	18
1 WFC	200 Liberty Street	577	13
Empire State Bldg	350 Fifth Ave	1250	7
1 Battery Park Plaza	Whitehall/Pearl/ State Street intersections	495	5
Embassy Suites Hotel	across Vesey St from WFC	~140	3
Gateway Plaza Bldg 200	Battery Park City	~340	3
Two Penn Plaza	Two Penn Plaza	412	2
Citibank Bldg	111 Wall Street	344	2
100 Church Street	Church Street between Barclay St & Park Place	229	1
95 Wall Street	NW corner Wall & Water Streets	~220	1
100 Wall Street	100 Wall Street	365	1

Note: [1] estimations multiplied number of stories by an average of 10 feet per story
Source: NYCAS (2004)

The use of glass as the primary material comprising the street-level terminal has the potential to result in day-time bird strikes. Klem (1989) estimated that the number of birds (resident and migratory individuals) killed by day-time window collisions at low-level structures (such as individual residences) ranges from approximately 100 million to close to one billion per year in the United States. Bird fatalities from window collisions do not necessarily occur immediately following the collision (Klem 1990a). Klem (1990b) concluded that birds do not recognize clear or reflective glass as a barrier, with those species whose activities occur on or near the ground, such as thrushes, wood warblers, and finches, being most vulnerable to daytime bird strike injury. Anything that increases the density of birds near windows would be expected to increase the daytime strike rate. Measures to reduce potential strikes are described in Section F, "Mitigation."

As described in Chapter 2, "Project Alternatives," two 40-foot-tall vent structures are necessary for the safe operation of the Preferred Alternative (piston relief and smoke evacuation). These structures would be located above Tunnels E and F within the Route 9A median. They would be buffered by trees and other plantings and would not be expected to result in losses to birds resulting from strikes. Additionally, noise levels at the vent structures resulting from the use of the vents would not be expected to exceed surrounding noise levels. Therefore, adverse impacts to terrestrial resources would not be expected to occur from the vent structures associated with the Preferred Alternative.

Other above-ground structures proposed as part of the Preferred Alternative would be one-story tall and, therefore, would not pose a substantial risk for bird strikes.

Floodplains

All of the elements of the Preferred Alternative, including the street-level entrances, emergency egress, and ventilation structures, within the floodplain would incorporate federal, state, and local regulations pertaining to flood protection measures similar to pre-September 11 conditions. A flood-proofing system would be required and would be designed so as not to require human intervention or mechanical actions. Therefore, no adverse impacts would be expected to occur to the water retention and flood control characteristics of the Project Site.

Water Quality and Aquatic Resources

During operation of the Preferred Alternative, stormwater would be diverted to the city combined sewer system. No stormwater would be discharged directly to the surface waters. In addition, stormwater systems would be constructed to reduce the post-development flow of water from the site as compared to pre-September 11, 2001 conditions. Pretreatment systems would remove approximately 80 percent of total suspended solids and 40 percent of total phosphorus before being discharged to the combined sewer system at the Project Site. The combined sewer system at the Project Site is pumped to the Newtown Creek Water Pollution Control Plant at the Manhattan Pump Station. Strategies for reuse of stormwater (see Chapter 11, "Infrastructure and Energy") would be explored in keeping with the green design, green construction, and sustainable design principles that have been developed (see Chapter 2, "Project Alternatives"). Therefore, adverse impacts to water quality or aquatic resources would not be expected to occur as a result of stormwater generated during the operation of the Preferred Alternative.

The river water cooling system includes two intakes located on the eastern shore of the Hudson River near the World Financial Center. River water cooling was used prior to September 11, 2001 and would be reestablished as part of the current redevelopment of the WTC site. The New York State Department of Environmental Conservation is currently reviewing PANYNJ's application to renew their State Pollutant Discharge Elimination System (SPDES) permit for the river water cooling system. As part of this application, PANYNJ has prepared a Best Technologies Available (BTA) study, which will be made publicly available upon the completion of NYSDEC's review. The study specifies measures to protect fish eggs and larve from entrainment and entrapment associated with the systems intake grates. These measures include:

- Using 3 gallons per minute (gpm)/ton chillers;
- Variable speed pumps; and
- Modifying the intake structure with 2 millimeter (mm) wedgewire screens to reduce the approach velocity to 0.5 feet per second (fps) with a corresponding river water flow of 120,000 gallons per minute (gpm).

While some level of impact to aquatic organisms due to entrainment of fish eggs (and much smaller numbers of larvae) is unavoidable utilizing the selected design, overall aquatic impacts are materially reduced from pre-September 11, 2001 conditions. The proposed system would eliminate the potential for impingement and would reduce entrainment of yolk-sac and post-yolk sac ichthyoplankton from pre-September 11, 2001 levels by an estimated 93 percent and 97

percent, respectively. In fact, virtually all (approximately 98 percent) of the entrained organisms are eggs, which are subject to high rates of natural mortality and fecundity. By excluding life stages of entrainable organisms with higher natural survival rates, the selected design minimizes the adverse environmental impact of the cooling water intake structures.

The river water cooling system would be closed-circuit such that water extracted from the Hudson River would not be mixed with potable water or stormwater as it travels through the system. Therefore, the system would not alter the composition of Hudson River water.

Regulations set forth at 6 NYCRR Part 704 establish water quality standards governing thermal discharges to the waters of the state. They require that "all thermal discharges to the waters of the State shall assure the protection and propagation of a balanced indigenous population of shellfish, fish and wildlife in and on the body of water" [6 NYCRR §704.1(a)]. Part 704 also sets forth specific criteria for discharges that, if met, would assure compliance with the standard. The criteria for estuarine discharges include a maximum surface temperature of 90°F, a limit on the lateral extent of a 4°F temperature rise to two-thirds of the width of the receiving river, and a limit on the cross-sectional area with a 4°F temperature rise to one-half of the river cross section. Because of Hudson River hydrodynamics, the maximum surface temperature of 90°F is the critical criterion to be met.

The BTA study specifies that the maximum designed change in temperature (ΔT) of the proposed river water cooling system is 10°F. Therefore, cooling water flow discharges would not result in temperatures in excess of the 90°F criterion, since the maximum ambient surface water temperature is 80°F.

Therefore, the cooling water discharges would have no potential impacts to water temperature and water quality within the Hudson River.

Endangered, Threatened, and Special Concern Species

As indicated by USFWS and NYNHP, no endangered, threatened, or special concern species or significant habitats are known to occur within the Project Site. Peregrine falcons that may occur within the vicinity of the Project Site would be expected to be acclimated to the urban conditions characteristic of the Project Site and adjacent areas. Therefore, they would not likely be impacted by the operation of the few above-ground features associated with the Preferred Alternative (e.g., street-level terminal building, north and south vent structures, or access to World Financial Center).

DESIGN YEAR (2025)

FUTURE COMMON TO ALL ALTERNATIVES

Terrestrial Resources

By 2025, it is assumed that the elements of the WTC Memorial and Redevelopment Plan would be complete, comprising open space areas, Memorial, museum and cultural facilities, retail, and up to 10 million square feet of office space in the five towers. The "green" corridors would also be complete between the Battery Park City and Route 9A. Draft plans for the WTC site include plantings at all of the new parks and along the reopened Fulton and Greenwich Streets. Because the elements of the WTC Memorial and Redevelopment Plan are expected to be completed and open by 2015, landscaped areas would have matured by 2025. These areas would be expected to provide some limited habitat for urban-tolerant wildlife, which include resident birds and small

mammals, and resting habitat for migratory songbirds in the spring and autumn, as discussed previously for the Future Common to All Alternatives in the opening year.

The proposed structures for the WTC Memorial and Redevelopment Plan would fully operational. The presence of all five proposed towers by 2025 would have the potential to result in more bird strikes than in the opening year of 2009. By 2025, potential operational measures that may reduce bird strikes, such as lighting modifications, would have been explored and implemented as appropriate to reduce the potential losses associated with bird strikes.

Floodplains

By 2025, the design year, it is assumed that all of the elements of the WTC Memorial and Redevelopment Plan would be complete. As indicated above, the WTC Memorial and Redevelopment Plan project is being addressed under a separate environmental review process. However, as discussed previously for the construction year, adverse impacts to the floodplain due to changes to the water retention and flood control characteristics of the Project Site would not be expected to occur from the elements of the WTC Memorial and Redevelopment Plan.

Water Quality and Aquatic Resources

As described previously for the Future Common to All Alternatives in the opening year, the reestablished cooling system on the WTC site would not adversely impact water quality and aquatic resources. Furthermore, proposed and ongoing projects aimed at improving water quality and aquatic resources in the New York/New Jersey Harbor Estuary have the potential to result in water quality and aquatic habitat improvements in the Lower Hudson River Estuary. These improvements would occur without the Project Alternatives, and some of the previously described project activities may continue through the design year.

NO ACTION ALTERNATIVE

Terrestrial Resources

Under the No Action Alternative, by the design year it is assumed that the temporary WTC PATH station would no longer be in operation. However, the discontinued use of the temporary station would not adversely effect terrestrial resources.

Floodplains

The discontinued use of the temporary WTC PATH station would not be expected to adversely affect the floodplain.

Water Quality and Aquatic Resources

No adverse impacts to water quality or aquatic resources would be expected to occur without operation of the temporary WTC station.

PREFERRED ALTERNATIVE

Terrestrial Resources

Because the only elements of the Preferred Alternative with the potential to affect terrestrial resources—the above-ground components, including the street-level terminal building at the northeast corner of the Project Site (west side of Church Street between Fulton and Dey streets), the vent structures, and the entrance adjacent to the Winter Garden—would not have changed

from the opening year evaluation, potential impacts in the design year would be expected to be similar to those of the opening year. Therefore, adverse impacts to terrestrial resources would not be expected to occur from the operation of the Preferred Alternative in 2025. Measures to reduce potential impacts to birds striking the surface of the street-level terminal, such as lighting modifications, would be explored to minimize potential impacts to resident and migratory birds from the operation of the street-level terminal building.

Floodplains

No changes to the floodplain in the Project Site are anticipated to occur as a result of the operation of the Project Alternatives between the opening year and the design year.

Water Quality and Aquatic Resources

Stormwater management for the Preferred Alternative in the design year would be similar to that described in the opening year. Stormwater would continue to be diverted to the city combined sewer system. Pretreatment systems would remove approximately 80 percent of total suspended solids and 40 percent of total phosphorus before being discharged to the combined sewer system at the Project Site. Strategies for reuse of stormwater (see Chapter 11, "Infrastructure and Energy") would be explored in keeping with the green design, green construction, and sustainable design principles that have been developed (see Chapter 2, "Project Alternatives"). Therefore, adverse impacts to water quality or aquatic resources would not be expected to occur as a result of stormwater generated during the operation of the Preferred Alternative.

Furthermore, as described under the "Future Common to All Alternatives," the reestablished river water cooling system would not adversely impact water quality and aquatic resources in the vicinity of the WTC site. Therefore, the Preferred Alternative's continued use of this system in the design year would also not result in adverse impacts.

Endangered, Threatened, and Special Concern Species

As indicated by USFWS and NYNHP, no endangered, threatened, or special concern species or significant habitats are known to occur within the Project Site. Peregrine falcons that may occur within the vicinity of the Project Site would be acclimated to the urban conditions characteristic of the Project Site and adjacent areas. Therefore, they would not likely be impacted by the operation of the few above-ground features associated this alternative in the design year.

E. MITIGATION

TERRESTRIAL RESOURCES

The preliminary design of the terminal building poses some concern for fatal strikes by migratory birds both during the day and at night. Measures that have the potential to reduce daytime bird strikes include:

- Place attractants (such as feeders or vegetation) either within 1 foot of the glass surface so that birds that have been attracted to them do not build up enough momentum to sustain serious injury if they hit the glass upon departure, or more than 33 feet from the glass surface;
- Transform glass into a recognizable obstacle by uniformly covering glass surfaces with a decorative grid with 2- to 4-inch intervals;

- Angle windows such that the panes reflect the ground instead of surrounding vegetation and sky;
- Minimize use of reflective glass; and
- Minimize the illumination of interiors behind clear glass and the visibility of indoor plants from outside (Klem 1990b, Klem 1991 in Ogden 1996).

Measures that have the potential to decrease bird strikes of nocturnal migrants include:

- minimize amount of light emanating upward during the migratory season; and
- minimize exterior floodlighting during the migratory season.

Measures to reduce potential impacts to birds from striking the surface of the street-level terminal, such as those presented above, and to minimize the potential for birds to enter the building through an opening in the top of the structure, would be explored during final design. PANYNJ will explore all feasible, cost effective, and practical measures for reducing bird strikes that are in keeping with the Terminal's design concept.

FLOODPLAINS

Existing and rehabilitated flood protection measures would be implemented as part of the Preferred Alternative. As such, flood control would meet or exceed pre-September 11, 2001 conditions. Stormwater discharges would be managed with an approved Stormwater Pollution Prevention Plans (SWPPPs) and established regulatory programs to minimize potential impacts to floodplains, groundwater, water quality, and aquatic resources. ✳

A. INTRODUCTION

The Preferred Alternative would be located within New York City's Coastal Zone Boundary as outlined in the Department of City Planning's Coastal Zone Boundary of New York City, June 1986 (see Figure 14-1). As such, this chapter examines the compliance of the Preferred Alternative with coastal zone policies.

B. METHODOLOGY

The federal Coastal Zone Management Act (CZMA) of 1972 was established to support and protect the distinctive character of the waterfront, and set forth standard policies for reviewing proposed development projects along coastlines. The CZMA emphasizes the primacy of state decision-making regarding the coastal zone. Section 307 of the CZMA (16 USC §1456), called the Federal Consistency provision, is a tool that states use to manage coastal uses and resources, and to facilitate cooperation and coordination with federal agencies. Federal Consistency is the CZMA requirement that federal agency activities having reasonably foreseeable effects on any land or water use or natural resource of the coastal zone must be consistent with the enforceable policies of a coastal state's federally approved Coastal Management Program (CMP). Federal Consistency reviews are the responsibility of the lead state agency that implements or coordinates the state's federally approved CMP.

The program responded to city, state, and federal concerns about the deterioration and inappropriate use of the waterfront. In response, New York State adopted its own CMP, designed to balance economic development and preservation by promoting waterfront revitalization and water-dependent uses while protecting fish and wildlife, open space and scenic areas, public access to the shoreline, and farmland; and minimizing adverse changes to ecological systems and erosion and flood hazards. CMP provides for local implementation when a municipality adopts a local waterfront revitalization program, as is the case in New York City. The program encourages coordination among all levels of government to promote sound waterfront planning and requires consideration of the program's goals in making land use decisions. The New York State Department of State (NYSDOS) administers the program at the state level, and the New York City Department of City Planning (NYCDCP) administers it in the city.

The *New York City Waterfront Revitalization Program* (WRP) is the City's principal coastal zone management tool. The WRP was originally adopted in 1982 and approved by NYSDOS for inclusion in the New York State CMP. The WRP establishes the City's policies for development and use of the waterfront and provides a framework for evaluating discretionary actions in the coastal zone. The WRP was revised and was approved by the City Council in October 1999. In August 2002, the NYSDOS and federal (i.e., the U.S. Army Corps of Engineers) authorities adopted the City's 10 WRP policies for projects located within its boundaries. This chapter reviews the 10 New York City coastal zone policies, which constitute the new WRP, and assesses, where applicable, the general consistency of the Preferred Alternative with these policies.

Potential effects on coastal resources include both direct and indirect impacts. Direct effects may result from temporary (construction) or permanent activities within the coastal zone or restriction of physical or visual access. Indirect effects may include the introduction of activities that result in growth-inducing impacts or may lead to other activities that further erode coastal resources. The potential effects on coastal resources from the Preferred Alternative are assessed for their consistency with the applicable WRP policies and to determine whether they would have an adverse effect on coastal resources.

C. DESCRIPTION OF THE AFFECTED ENVIRONMENT

As shown in Figure 14-1, the majority of the Project Site is located within the coastal zone. In the vicinity of the WTC site, the coastal zone boundary generally follows Greenwich Street. However, it expands eastward along Vesey and Liberty Streets to Church Street, and therefore includes the entire WTC site. This coastal zone boundary was not changed as a result of the terrorist attacks of September 11, 2001.

D. PROBABLE IMPACTS OF THE PROJECT ALTERNATIVES

New York City's WRP includes 10 policies designed to maximize the benefits derived from economic development, environmental preservation, and public use of the waterfront, while minimizing the conflicts among those objectives. Each Project Alternative is presented below, followed by a discussion of its applicability to and consistency with the appropriate policies.

NO ACTION ALTERNATIVE

The No Action Alternative may preclude PATH operations between New Jersey and Lower Manhattan at some point in the future and would result in the increased use of other modes of travel, such as automobiles, buses, subways, ferries, and commuter rail. The lack of subgrade pedestrian concourses, which would be constructed as part of the Preferred Alternative, would limit mobility through and around the WTC site, and, thus, access to the waterfront. Specifically, the No Action Alternative would not support the following policies of the WRP.

Policy 1: Support and facilitate commercial and residential development in areas well-suited for such development.

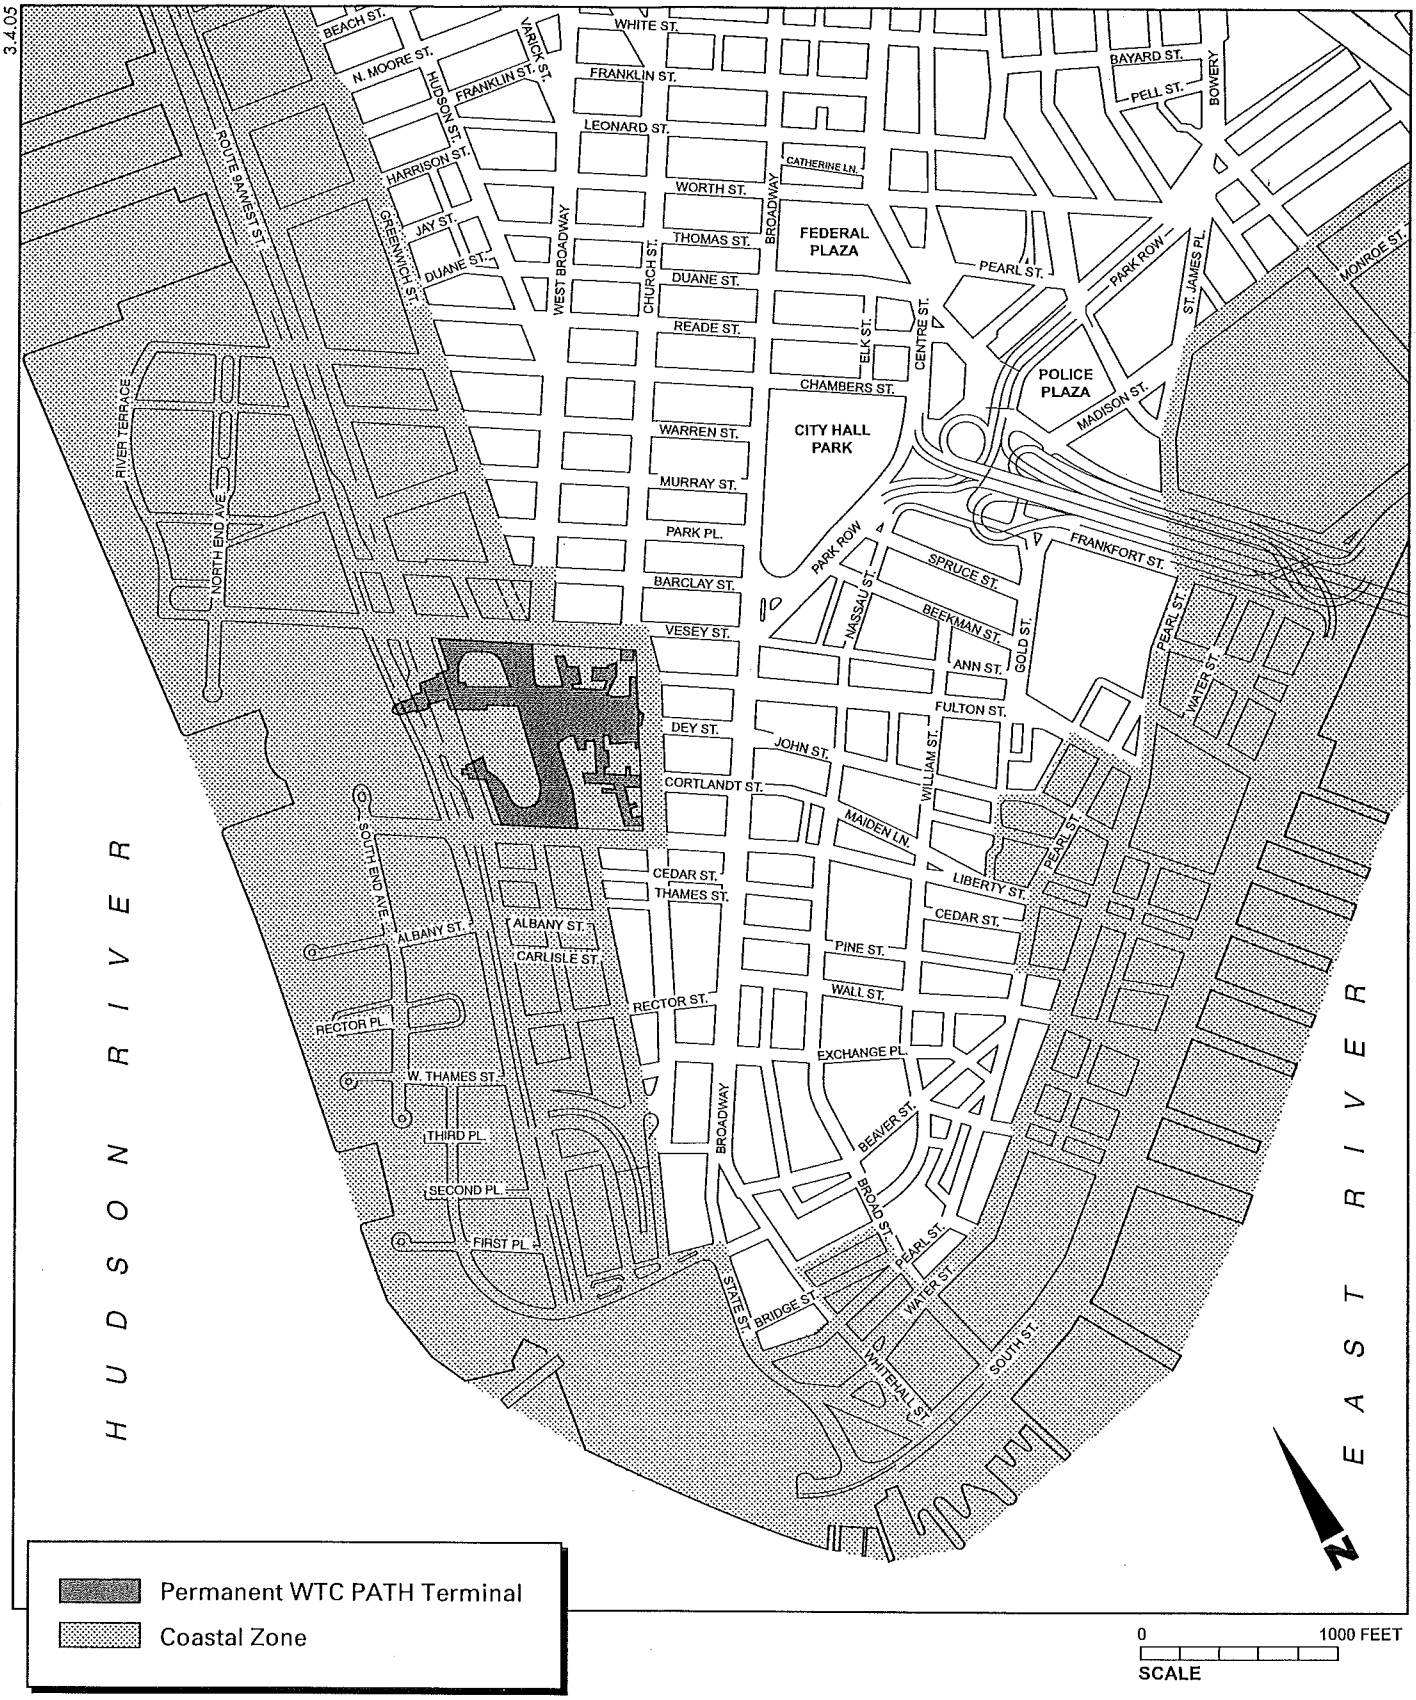
As described in Chapter 5, "Socioeconomic Conditions," the Preferred Alternative is a component of the economic revitalization and future development of Lower Manhattan.

Policy 8: Provide public access to and along New York City's coastal waters.

Although the No Action Alternative would not preclude waterfront access, it would eliminate subgrade concourses, which would improve access between the WTC site, points east, and the Battery Park City waterfront.

PREFERRED ALTERNATIVE

Policy 1: Support and facilitate commercial and residential development in areas well-suited to such development.



PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Figure 14-1
Coastal Zone Boundary

Policy 1.1: Encourage commercial and residential redevelopment in appropriate coastal zone areas.

The Preferred Alternative would include approximately 5,000 square feet of accessory retail within the Terminal. This alternative would help to encourage commercial and residential development in the area by facilitating the movement of workers and visitors to the Project Site and surrounding area.

Policy 1.2: Encourage non-industrial development that enlivens the waterfront and attracts the public.

The Preferred Alternative would replace and enhance the preexisting transit facility. While the Terminal itself would not enliven the waterfront, it would facilitate the movement of people to and from the Project Site to the surrounding waterfront. The Permanent Terminal's underground pedestrian connection to the World Financial Center would facilitate movement of workers and visitors to the World Financial Center and the waterfront open spaces in Battery Park City and Hudson River Park.

Policy 1.3: Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

The construction of the Preferred Alternative would replace and improve the preexisting infrastructure damaged during the September 11, 2001 attacks on the WTC. This alternative would reestablish the critical connection between PATH and New York City subway lines (1, 9, E, R, and W) to facilitate movement of employees, commuters, and visitors to and around Lower Manhattan. In addition to reestablishing the connections that existed before September 11, 2001, the new facility would link with the Fulton Street Transit Center, Hudson River ferries, and a proposed commuter rail connection to JFK Airport. The infrastructure to serve the operation of the Preferred Alternative is consistent with this policy.

Policy 2: Support water-dependent and industrial uses in New York City coastal areas that are well-suited to their continued operation.

Policy 2.1: Promote water-dependent and industrial uses in Significant Maritime and Industrial Areas.

The Project Site is not located in a Significant Maritime and Industrial Area; therefore, this policy is not applicable.

Policy 2.2: Encourage working waterfront uses at appropriate sites outside the Significant Maritime and Industrial Areas.

The Preferred Alternative does not have direct waterfront access. However, the terminal would aid the movement of people to and from the Project Site to the surrounding waterfront.

Policy 2.3: Provide infrastructure improvements necessary to support working waterfront uses.

Construction of the Preferred Alternative is an infrastructure improvement that would facilitate the movement of workers between New Jersey and Manhattan. While it would not specifically support working waterfront uses, this alternative would introduce a pedestrian connection to the World Financial Center, which would enhance the

movement of workers and visitors to and from commercial uses in the World Financial Center, which is located in close proximity to the waterfront.

Policy 3: Promote use of New York City's waterways for commercial and recreational boating and water-dependent transportation centers.

Policy 3.1: Support and encourage recreational and commercial boating in New York City's maritime centers.

The Project Site, which is the site of the former WTC PATH Terminal, is in close proximity to the recreational/commercial boating and ferry transportation at the World Financial Center. This alternative will promote the use of this waterfront area by providing improved pedestrian access.

Policy 3.2: Minimize conflicts between recreational, commercial, and ocean-going freight vessels.

The Preferred Alternative does not involve recreational, commercial, or ocean-going freight vessels; therefore, the project would not create conflicts among these vessels.

Policy 3.3: Minimize impact of commercial and recreational boating activities on the aquatic environment and surrounding land and water uses.

The construction and operation of the Preferred Alternative would not involve any commercial or recreational boating activities; therefore, this policy is not applicable.

Policy 4: Protect and restore the quality and function of ecological systems within the New York City coastal area.

Policy 4.1: Protect and restore the ecological quality and component habitats and resources within the Special Natural Waterfront Areas, Recognized Ecological Complexes, and Significant Coastal Fish and Wildlife Habitats.

The Project Site is not located within a Special Natural Waterfront Area or Recognized Ecological Complex. However, the Preferred Alternative would use river water cooling for its Heating, Ventilation, and Air Conditioning (HVAC) systems, which may impact aquatic habitats within the Hudson River. The river water cooling system includes two intakes located on the eastern shore of the Hudson River near the World Financial Center. River water cooling was used prior to September 11, 2001 and would be reestablished as part of the current redevelopment of the WTC site. The New York State Department of Environmental Conservation is currently reviewing PANYNJ's application to renew their State Pollutant Discharge Elimination System (SPDES) permit for the river water cooling system. As part of this application, PANYNJ has prepared a Best Technologies Available (BTA) study that specifies measures to protect fish eggs and larve from entrainment and entrapment associated with the systems intake grates. These measures include:

- Using 3 gallons per minute (gpm)/ton chillers;
- Variable speed pumps; and
- Modifying the intake structure with 2 millimeter (mm) wedgewire screens to reduce the approach velocity to 0.5 feet per second (fps) with a corresponding river water flow of 120,000 gallons per minute (gpm).

While some level of impact to aquatic organisms due to entrainment of fish eggs (and much smaller numbers of larvae) is unavoidable utilizing the selected design, overall aquatic impacts are materially reduced from pre-September 11, 2001 conditions. The proposed system would eliminate the potential for impingement and would reduce entrainment of yolk-sac and post-yolk sac ichthyoplankton from pre-September 11, 2001 levels by an estimated 93 and 97 percent respectively. In fact, virtually all (approximately 98%) of the entrained organisms are eggs, which are subject to high rates of natural mortality and fecundity. By excluding life stages of entrainable organisms with higher natural survival rates, the selected design minimizes the adverse environmental impact of the cooling water intake structures.

Policy 4.2: Protect and restore tidal and freshwater wetlands.

There are no New York State Department of Environmental Conservation (NYSDEC) or U.S. Army Corps of Engineers (ACE) mapped tidal or freshwater wetlands on the Project Site. Therefore, this policy is not applicable.

Policy 4.3: Protect vulnerable plant, fish, and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.

Requests for information on rare, threatened or endangered species within the immediate vicinity of Project Site were submitted to United States Fish and Wildlife Service (USFWS), the NYSDEC Natural Heritage Program (NYNHP), and National Marine Fisheries Service (NMFS). USFWS indicated that no federally listed or proposed endangered or threatened species were currently known to exist in the vicinity of the Project Site. NYNHP also indicated that they had no records of known occurrences of rare or state-listed animals or plants, significant natural communities, or other significant habitats, on or in the immediate vicinity of the Project Site. NMFS identified seasonal use of the Hudson River by shortnose sturgeon and occasional transient use by four species of marine turtle. However, the Terminal is not directly located along the Hudson River waterfront; therefore, these intermittent transient species would not be disturbed. As a result, this alternative is consistent with this policy (see Chapter 13, "Natural and Water Resources").

Policy 4.4: Maintain and protect living aquatic resources.

See Policy 4.1, above.

Policy 5: Protect and improve water quality in the New York City coastal area.

Policy 5.1: Manage direct or indirect discharges to waterbodies.

Potential impacts to water quality and aquatic resources associated with construction and stormwater discharge from the Terminal would be managed with an approved Stormwater Pollution Prevention Plan (SWPPP), in conformance with NYSDEC SPDES permit requirements. Construction groundwater discharges and stormwater generated within the Project Site would be directed to the municipal stormwater system. Best Management Practices for erosion and sediment control would be implemented to minimize potential impact to the municipal stormwater system (see Chapter 13, "Natural and Water Resources").

As described above, for Policy 4.1, the Preferred Alternative would employ a river water cooling system. NYCDEC is currently reviewing PANYNJ's application to renew the SPDES permit for the WTC site. The application includes a BTA study that includes strategies to reduce impacts to water quality.

The river water cooling system would be closed-circuit such that water extracted from the Hudson River would not be mixed with potable water or stormwater as it travels through the system. Therefore, the system would not alter the composition of Hudson River water.

Regulations set forth at 6 NYCRR Part 704 establish water quality standards governing thermal discharges to the waters of the state that requires. They require that "all thermal discharges to the waters of the State shall assure the protection and propagation of a balanced indigenous population of shellfish, fish and wildlife in and on the body of water" [6 NYCRR §704.1(a)]. Part 704 also sets forth specific criteria for discharges that, if met, would assure compliance with the standard. The criteria for estuarine discharges include a maximum surface temperature of 90°F, a limit on the lateral extent of a 4°F temperature rise to two-thirds of the width of the receiving river, and a limit on the cross-sectional area with a 4°F temperature rise to one-half of the river cross section. Because of Hudson River hydrodynamics, the maximum surface temperature of 90°F is the critical criterion to be met.

The BTA study specifies that the maximum designed change in temperature (ΔT) of the proposed river water cooling system is 10°F. Therefore, cooling water flow discharges would not result in temperatures in excess of the 90°F criterion, since the maximum ambient surface water temperature is 80°F.

Therefore, the cooling water discharges would have no potential impacts to water temperature and water quality within the Hudson River.

Policy 5.2: Protect the quality of New York City's waters by managing activities that generate non-point source pollution.

See policy 5.1, above.

Policy 5.3: Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes or wetlands.

Construction of the Preferred Alternative would not require any excavation or the placement of fill in navigable waters or near marshes, estuaries, tidal marshes, or wetlands. Therefore, this policy is not applicable.

Policy 5.4: Protect the quality and quantity of groundwater, streams, and the sources of water for wetlands.

The site does not contain any potable groundwater, nor does it contain streams or the source of water for wetlands. Therefore, this policy is not applicable.

Policy 6: Minimize the loss of life, structures, and natural resources caused by flooding and erosion.

Policy 6.1: Minimize losses from flooding and erosion by employing non-structural and structural management measures appropriate to the condition and use of the property to be protected and the surrounding area.

The Project Site is partially located within the 100-year flood plain. The 100-year floodplain is regulated by the Federal Emergency Management Agency (FEMA), and is defined as areas that have a 1 percent chance of flooding each year due to storms. The 100-year floodplain is usually characterized by dry land, but has the potential of being covered with flood water. Executive Order 11988 and its implementing regulations, 24 CFR Part 55, require federal agencies to consider alternatives to avoid adverse effects and incompatible development in the floodplains.

The Preferred Alternative would not alter the natural features of the shoreline or any structural or non-structural flood or erosion control measures. The project would not increase the amount of impervious surface on the site as compared to the pre-September 11, 2001 condition, and thus would not increase flood hazards on or adjacent to the Project Site. Therefore, the buildings and facilities would be built to withstand these flood conditions so as not to be damaged in the event of a flood. Consistent with this policy, this will minimize the potential for property damage and endangering human life (see Chapter 13, "Natural and Water Resources.")

Policy 6.2: Direct public funding for flood prevention or erosion control measures to those locations where the investment will yield significant public benefit.

The Preferred Alternative does not involve public funding for such measures; therefore, the proposed policy is not applicable.

Policy 6.3: Protect and preserve non-renewable sources of sand for beach nourishment.

There are no non-renewable sources of sand on the Project Site; therefore, this policy does not apply.

Policy 7: Minimize environmental degradation from solid waste and hazardous substances.

Policy 7.1: Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution, and prevent degradation of coastal ecosystems.

As discussed in Chapter 12, "Contaminated Materials," it is not anticipated that contaminated materials will be encountered within the western portion of the Project Site during construction of the Preferred Alternative. However, excavation/tunneling activities associated with the proposed egress routes may encounter fill material, which could include contaminants and/or contaminated groundwater. Construction activities would be performed using appropriate construction and engineering practices. In addition, a Health and Safety Plan (HASP) would be prepared and implemented (see Chapter 12).

Operation of both the Permanent WTC PATH Terminal, specifically the PATH train system, would include the use of limited quantities of hazardous materials and petroleum products. These materials are used in conjunction with the current system and such materials are not stored on the WTC site. No changes in materials handling for the PATH system are anticipated with the proposed project; thus, there would continue to be no materials storage at the Project Site. The Port Authority of New York and New Jersey (PANYNJ) has established a series of standard operating procedures, which include measures to be undertaken in the event of a discharge of hazardous materials or petroleum products. These procedures would continue to apply in the future with the Preferred Alternative.

Policy 7.2: Prevent and remediate discharge of petroleum products.

See Policy 7.1, above.

Policy 7.3: Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.

See Policy 7.1, above. The minimal waste generated by this alternative would be hauled by a licensed waste hauler according to applicable laws and regulations (see Chapter 12).

Policy 8: Provide public access to and along New York City's coastal waters.

Policy 8.1: Preserve, protect and maintain existing physical, visual, and recreational access to the waterfront.

The Project Site is located both above and below ground on a site that was previously the WTC and PATH Terminal. The original PATH terminal had no physical, visual, or recreational access to the waterfront to be preserved, protected, or maintained. As part of the Preferred Alternative, a pedestrian connection would be constructed between the Terminal and Battery Park City. This connection would provide better access to the west side of Manhattan and the waterfront open spaces within Battery Park City and Hudson River Park.

Policy 8.2: Incorporate public access into new public and private development where compatible with proposed land use and coastal location.

See Policy 8.1.

Policy 8.3: Provide visual access to coastal lands, waters, and open space where physically practical.

The project has been planned in coordination with the redevelopment of the WTC. A master plan for the site will be implemented and includes approximately 5.5 acres of open space. The development of the Preferred Alternative would not preclude the WTC master plan.

Policy 8.4: Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.

The Preferred Alternative would be constructed on the site of the former World Trade Center and PATH Terminal. The Preferred Alternative would not preclude the construction of open space uses as part of the WTC Memorial and Redevelopment Plan.

Policy 8.5: Preserve the public interest in and use of lands and waters held in public trust by the State and City.

The Preferred Alternative would not hinder current accessibility to the waterfront nor interfere with the continued use or ownership of land and waters held in the public trust as the Preferred Alternative is not located directly along the waterfront. The underground pedestrian connection between the terminal and the World Financial Center would improve movement of workers and visitors to the waterfront. Thus, the public interest in the use of lands and water held in public trust (i.e., Battery Park City

esplanade and Hudson River Park) would be encouraged and preserved. As a result, this alternative would be consistent with this policy.

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

Policy 9.1: Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.

The visual character of the Hudson River waterfront and Lower Manhattan consist of an urban landscape with tall commercial and industrial buildings. The only visible elements of the Permanent WTC PATH Terminal would be the terminal building, which would provide street-level access to the WTC site and to Greenwich and Church Streets and the north and south ventilation structures to be constructed in the Route 9A median. The Terminal would be modern in design and lower in height than the adjacent buildings to its north and south, and would be consistent with view corridors in the WTC master plan. The ventilation structures would replace two 12-foot ventilation structures for the original PATH terminal, would be of long and slender massing, and would stand 40 feet in height. It is anticipated that the structures would be clad in reflective material, in keeping with modern material used on buildings in the immediate area. The terminal and ventilation structures are in scale and character with existing visual resources in Lower Manhattan and would be consistent with protecting and enhancing the existing scenic values and character of the area. As discussed in Chapter 7, "Urban Design and Visual Resources," it is likely that the terminal would become an important visual resource on the Project Site.

Policy 9.2: Protect scenic values associated with natural resources.

There are no natural resources on the Project Site, nor is it located in a Special Natural Area District, Special Natural Waterfront Area, or Recognized Ecological Complex; therefore, this policy does not apply.

Policy 10: Protect, preserve, and enhance resources significant to the historical, archaeological, and cultural legacy of the New York City coastal area.

Policy 10.1: Retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City.

As discussed in Chapter 6, "Cultural Resources," to avoid, minimize, and mitigate adverse effects to historic resources during construction of the Preferred Alternative, a Memorandum of Agreement pursuant to Section 106 of the NHPA has been executed. As specified in the MOA, a Construction Protection Plan(s)—based on the requirements laid out in the "New York City Department of Buildings Technical Policy and Procedure Notice #10/88"—would be developed in consultation with the State Historic Preservation Officer (SHPO) and implemented before commencement of any excavation or construction. In addition, as described in Chapter 10, "Noise and Vibration," special vibration protection measures would be implemented to protect historic resources from increased vibration levels associated with construction activities. Implementation of the Construction Protection Plan(s) and the vibration protection measures would avoid or minimize the potential for adverse effects to historic resources during construction.

Measures to mitigate adverse effects to the National Register-eligible WTC site have been specified as part of the Memorandum of Agreement for the project (see Appendix B).

Once constructed, it is anticipated that the Preferred Alternative would continue the existing trend of modern buildings juxtaposed against the historic fabric of Lower Manhattan. The Terminal's design will also incorporate measures to avoid, minimize, or mitigate adverse impacts to remaining remnants and structures on the WTC site per the stipulations of the executed Memorandum of Agreement for the Permanent WTC PATH Terminal. The measures include the preservation of the passageway to the E train, architectural treatments on the platform level, and visual access to remaining resources, where possible. PANYNJ would coordinate with SHPO and the project's Section 106 consulting parties on the incorporation of these elements as the Terminal's design moves forward. Overall, the Terminal is not expected to have any contextual or visual effects on any known or potential historic resources (see Chapter 6, "Cultural Resources").

Policy 10.2: Protect and preserve archaeological resources and artifacts.

(See Policy 10.1, above.) PANYNJ would coordinate with the Lower Manhattan Development Corporation (LMDC) prior to the start of construction to determine whether any potentially sensitive areas have already been tested as part of the WTC Memorial and Redevelopment Plan. If necessary, Phase IB testing, which involves subsurface testing to try to determine whether any resources are actually present, would take place in potentially sensitive areas prior to the start of construction.

Construction of the pedestrian connection to the World Financial Center may affect a portion of the Hudson River Bulkhead, buried underground along the western edge of Route 9A. An agreement would be developed between PANYNJ, FTA, and SHPO in order to mitigate any adverse effects, if necessary (see Chapter 6, "Cultural Resources").

E. MITIGATION

The Preferred Alternative reflects a commitment to consistency with WRP coastal policies and the WRP's goals of enlivening the waterfront and attracting the public to the city's coastal areas. The Preferred Alternative would introduce a pedestrian connection to the World Financial Center, which would enhance the movement of workers and visitors to and from commercial uses in the World Financial Center, which is located in close proximity to the waterfront.

Under the policies of the CMP and WRP, the Preferred Alternative would not have an adverse impact on coastal resources. Therefore, the Preferred Alternative would be consistent with applicable policies in the CMP and WRP. ✳

A. INTRODUCTION

The federal Council on Environmental Quality's regulations implementing the procedural provisions of the National Environmental Policy Act (NEPA), set forth in 40 CFR Part 1500-1508, require federal agencies to consider the environmental consequences of their actions, including not only direct and indirect effects, but also cumulative effects.

The other chapters of this Environmental Impact Statement (EIS) assess the potential direct and indirect effects of the No Action Alternative and the Preferred Alternative for a range of technical areas. This chapter addresses cumulative impacts of the Preferred Alternative in combination with other reasonably foreseeable actions.

Cumulative impacts result from the incremental consequences of an action (the project) when added to other past and reasonably foreseeable future actions (40 CFR 1508.7). The cumulative effects of an action may be undetectable when viewed in the individual context of direct and indirect impacts, but when added to other actions can eventually lead to a considerable environmental change. Cumulative impacts are the net result of both the proposed project and the other projects that could affect the same resource.

The redevelopment of Lower Manhattan includes transportation and development projects being sponsored by both public and private groups. Although funded and planned separately, and having independent utility from each other, the construction and operation of these various projects would have a cumulative effect on the character and quality of Lower Manhattan and the region, as a whole, both during construction and in the long-term. Recognizing the potential impacts of such large-scale development in a relatively small geographic area, the lead federal agencies, in cooperation with the local project sponsors, developed a framework for the analysis of cumulative effects for projects being reviewed under the National Environmental Policy Act (NEPA). To guide this process, the U.S. Department of Transportation, Federal Transit Administration (FTA) prepared the *Approach to Cumulative Effects Analysis for the Lower Manhattan Recovery Effort* (July 2003).

The approach described in FTA's guidance ensures consistency among projects through a coordinated set of analysis assumptions and methodologies for all of the transportation recovery projects. As individual projects advance through the NEPA process, the analysis and any identified impacts are incorporated into the documentation of later projects to ensure a consistent, up-to-date, and comprehensive evaluation of potential cumulative effects.

This cumulative effects assessment considers the five major federally funded Lower Manhattan Recovery Projects as well as other public and private developments in the vicinity of the Port Authority of New York and New Jersey's (PANYNJ) Permanent World Trade Center (WTC) PATH Terminal (see Figure 15-1). This analysis also incorporates the assumptions and results from the following environmental documents, which are being prepared for the other, federally-sponsored Lower Manhattan Recovery Projects:

- *World Trade Center Memorial and Redevelopment Plan Final Generic Environmental Impact Statement (FGEIS)*, which was published by the U.S. Department of Housing and Urban Development (HUD) and the Lower Manhattan Development Corporation LMDC in April 2004;
- *Fulton Street Transit Center Final Environmental Impact (FEIS)* which was published by the FTA and the Metropolitan Transportation Authority (MTA) New York City Transit (NYCT) in October 2004;
- *South Ferry Terminal Environmental Assessment Statement (EA)*, which was published by the FTA and MTA/NYCT in May 2004; and
- *Route 9A Project Draft Supplemental Environmental Impact Statement (DSEIS)*, which was published by the U.S. Department of Transportation, Federal Highway Administration (FHWA) and the New York State Department of Transportation in May 2004.

This study focuses on subject areas with the most potential for cumulative adverse effects from the proposed projects in Lower Manhattan. The local project sponsors have coordinated amongst themselves and with federal agencies to develop consistent methodologies, assumptions, data sources, and impact criteria for the evaluation of impacts for the five cumulative effects subject areas: access and circulation; air quality; noise and vibration; cultural resources; and economic conditions. Furthermore, the project sponsors have agreed to a consistent set of Environmental Performance Commitments (EPCs) for these resource areas to be implemented as part of their projects in order to minimize or avoid adverse impacts during construction.

The coordination among the project sponsors began in the Spring of 2003. These efforts have included working group meetings with all of the project sponsors to address general coordination issues as well as technical subjects (e.g. construction assessment; traffic modeling; air quality emissions factors; etc.). Some of these coordination meetings have also involved participation from other local and state agencies such as the New York City Department of Transportation (NYCDOT), the New York State Historic Preservation Officer (SHPO), and the New York State Department of Environmental Conservation (NYSDEC). During the DEIS phase for the WTC Permanent PATH Terminal, these meetings were held at least weekly and sometimes two or three times per week.

Coordination efforts have continued since publication of the DEIS for the Permanent WTC PATH Terminal. As described in Chapter 9, "Air Quality" and Chapter 10, "Noise and Vibration," PANYNJ has worked with MTA/NYCT to refine EPCs and have furthered their commitment to reduce emissions, noise, and vibrations during construction. PANYNJ has also committed to the coordination of potential impacts to historic and archaeological resources through the execution of the Permanent WTC PATH Terminal Memorandum of Agreement (MOA), which was prepared pursuant to Section 106 of the National Historic Preservation Act. Furthermore, New York State Governor George Pataki has established the Lower Manhattan Construction Command Center, which will oversee coordination efforts among the Lower Manhattan Recovery Projects as efforts move forward.

B. METHODOLOGY

The cumulative effects analysis focuses on the five categories of concern identified in FTA's Approach to Cumulative Effect's for the Lower Manhattan Recovery Efforts, which are also

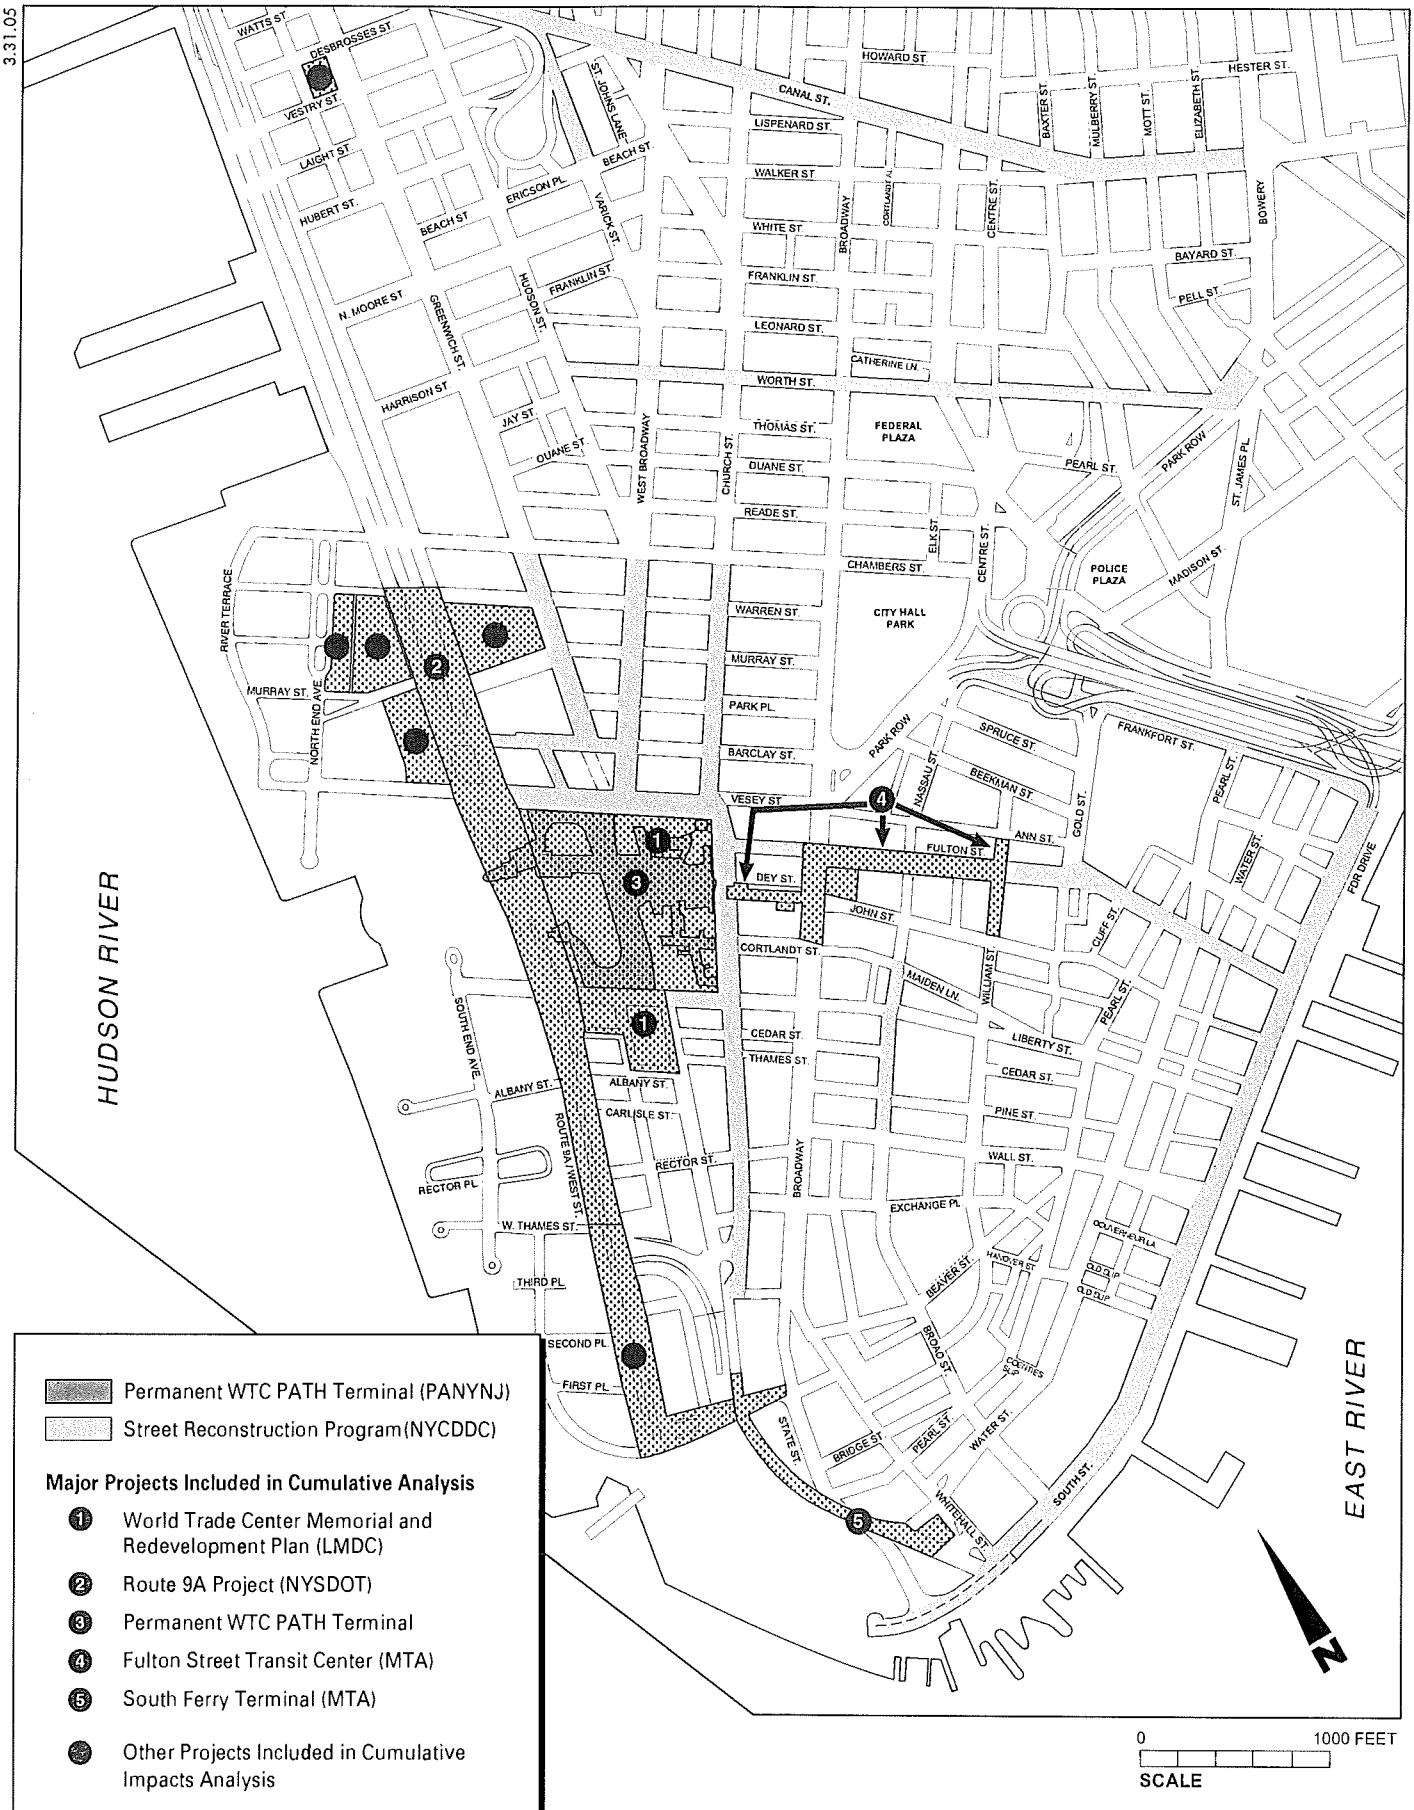


Figure 15-1

Lower Manhattan Projects Planned for Construction in the Critical Analysis Year

reflected in the Environmental Analysis Framework that was developed by PANYNJ, LMDC, MTA/NYCT and NYSDOT. As noted above, the five categories are:

- Air Quality
- Noise and Vibration
- Cultural Resources
- Access and Circulation
- Economics (e.g., Effects on Local Businesses)

It should be noted that the access and circulation category has been assessed under the typical methodology for projects in New York City of vehicular traffic, pedestrians, and transit services. Also, the nature of the cumulative effects analysis differs depending upon the category. For the transportation (i.e. traffic, pedestrians and transit), air quality and noise categories, predictive quantitative models were used extensively to determine the impacts. For cultural resources and economics a more qualitative approach was undertaken. With respect to cultural resources, the cumulative effects analysis focused on National or State Register listed or eligible and locally designated or eligible historic or archaeological resources within the Area of Potential Effect (APE) for each individual project and noted where effects may be cumulative. For the effects on local businesses, much of the analysis focused on commitments by project sponsors to maintain access during construction. Since much of these effects are site-specific (i.e., maintenance of specific sidewalk areas, curb-cuts, street closings, etc.) the necessary detail developed during the design phases was not available. As discussed in the individual environmental documents, the project sponsors are committed to developing a coordinated construction and traffic coordination plan which will ultimately mitigate potential adverse effects on access to local businesses and cultural sites during the construction period.

The cumulative effects analysis considers both the potential short-term (construction period) and long-term (operational period) beneficial and adverse impacts of the five Lower Manhattan Recovery Projects, as well as other projects that are anticipated to be undertaken in Lower Manhattan. However, it should be noted that the short-term or construction-related effects are generally adverse while the long-term effects are generally beneficial. The Lower Manhattan Recovery Projects have been planned with the specific purpose of supporting the economic recovery of Lower Manhattan while enhancing the environment of the area. This is particularly true with respect to the transportation projects that are expected to improve overall transportation service to the lower Manhattan area as compared to pre-September 11, 2001 conditions. However, to satisfy these objectives and needs, the area would experience an intense level of construction over the next several years. Therefore, in the cumulative effects analysis a greater focus has been given to the potential adverse effects during construction of these projects.

In addition, the long-term effects of the individual projects do not necessarily act in concert to the degree that the short-term effects do. For example, while undergoing construction, all of the proposed projects would lead to increases in traffic, air pollutant emissions and noise concurrently. These increases are additive and result in a higher level of impact than any project taken individually. However, the same is not necessarily true of the long-term effects since each project mostly affects different aspects of the Lower Manhattan environment. For example, the transit projects (with the exception of the No Action Alternative for the Permanent WTC PATH Terminal) would have a negligible effect on traffic and, therefore, air quality and noise levels on the major arterials (Route 9A, Church Street and Broadway) in Lower Manhattan. However, the different alternatives under study for Route 9A have a much more pronounced effect on conditions along the above-mentioned roadways. For street traffic and its related effects on noise

and air quality, the combined effect of Route 9A together with redevelopment of the WTC site would determine the long-term effects on these resources. This is not to say that the five major recovery projects do not have long-term cumulative effects that need to be considered. For example, each project affects pedestrian conditions that overlap in specific areas and need to be considered cumulatively.

With the above in mind, a coordinated effort was undertaken by the project sponsors of the Lower Manhattan Recovery Projects in an effort to provide consistency throughout the respective project's environmental reviews. While this coordination effort has resulted in very consistent findings between the documents, differences do occur. This is particularly true of the long-term effects where projects may have different future analysis years or use different criteria to evaluate their specific impacts. Some of these differences are discussed below. However, the construction impact assessment is nearly identical in each of the five documents with minor differences with respect to specific impact criteria (e.g., traffic and noise) used by the three different agencies (i.e., FTA, FHWA and HUD).

APPROACH TO CONSTRUCTION PERIOD EFFECTS

For the short-term impact assessment the analysis considered the cumulative effects of the five federally funded Lower Manhattan Recovery Projects described above. Other privately-funded initiatives were also considered but were not explicitly modeled as part of the impact assessment because these projects were either considered too small to influence the outcome or were part of the baseline (No Action) alternative on which the cumulative assessment was built.

DATA DEVELOPMENT AND BASELINE CONDITIONS

The following steps were performed to develop a consistent set of assumptions and baseline data to be used in each project's cumulative effects analysis:

Project sponsors provided information to allow development of a construction schedule for the five projects. A master schedule was developed showing major phases of construction for each project which was used in all the environmental documents.

- Once the schedules were developed, a critical analysis year was selected which was used in the modeling analyses to determine the greatest potential for construction-related impacts. For the Permanent WTC PATH Terminal DEIS, 2006 was determined as the critical analysis year and was used in the impact assessment to test the effectiveness of the EPCs and to determine whether additional mitigation was needed. As described in more detail below, the construction schedule for the Permanent WTC PATH Terminal, WTC Memorial and Redevelopment Plan, and Route 9A Project are delayed, and it is more likely that their construction would peak in 2007 or 2008, but construction of the South Ferry Terminal and Fulton Street Transit Center Projects is still expected to peak in 2006. Although the peak construction periods for the Lower Manhattan Recovery Projects would not overlap as predicted previously, this FEIS retains a critical analysis year that includes the peak construction activities for all five of the Lower Manhattan Recovery Projects.
- With the critical analysis year determined, the baseline conditions for the impact assessments were developed.
  - Access and Circulation – The project sponsors used the same set of baseline traffic, pedestrian and transit conditions to perform the impact assessment. Post-September 11, 2001 data collected by each project was assembled into one coherent set of data

representing conditions for the 2003 baseline. This included traffic volumes and speeds, pedestrian intersection and crosswalk data and usage for elements of nearby transit stations.

- Noise and Vibration – Project sponsors shared data on existing noise level measurements to develop a complete representation of existing conditions in Lower Manhattan.
- Air Quality – Project sponsors agreed upon background concentrations to be used in the impact assessment based on NYSDEC monitoring data.
- Cultural Resources – A list of resources (both historic structures and archaeological resources) were developed in concert and submitted to SHPO for concurrence. This resulted in one set of eligible resources in the study area. In addition, the federal project sponsors and the federal agencies prepared a coordinated Determination of Eligibility for the WTC site pursuant to Section 106 of the National Historic Preservation Act (NHPA).
- Economic Conditions – A comprehensive land use database was developed for existing conditions based on the NYC Real Property Assessment Database updated with field surveys. This data was then used in the MTA/NYCT's Regional Forecasting Model and shared with the project sponsors.

- Once the post- September 11, 2001 baseline conditions for 2003 were determined, the project sponsors developed the future (2006) conditions to be used in the construction impact assessment. This was accomplished by developing an agreed upon series of factors for traffic, pedestrians and transit usage based on known development projects and general background growth for the area.
- Once the 2006 critical analysis year was determined, the details of the construction activities for each project were developed. These details are necessary for completion of the traffic, air and noise impact assessment. Information for site-specific effects on local businesses was not generally available to the same level of detail. The information provided included the actual sub-phases of construction activity and what equipment would be required, for how long and where it would be generally operating. In addition, the total trucking activity for each sub-phase was determined and summed across all projects. The initial estimates were completed for the FGEIS for the WTC Memorial and Redevelopment Plan since it was published in April of 2004. Since that time, the information for the Route 9A Project has been updated by their design team. This information was shared among the project sponsors enabling the most current information on truck generation, equipment usage and placement to be used in each project's impact assessment.

IMPACT ASSESSMENT

Access and Circulation

Based on the information developed in the construction scenarios, an estimated 2,000 truck trips per day would be expected during peak conditions for the five projects. The project sponsors then developed an agreed upon set of truck routes, based on NYC truck routes, as well as the temporal distribution of the trips, for the traffic impact assessment. All traffic and pedestrian impacts were assessed based on methodologies from the Highway Capacity Manual. While some

projects employed different software versions for their analysis, the procedures were essentially the same.

For pedestrian access during construction, the project sponsors relied on the construction staging and the potential street/sidewalk closings to determine where pedestrian impacts may occur. In some cases, the issue may be related to a single project (Broadway and Fulton Street) rather than a cumulative effect (Church Street from Vesey to Liberty Streets). For the cumulative effects assessment, the analysis focused on specific corridors of movements that would be affected by more than one project. For example, the movement of pedestrians east-west from the subway stations on Church Street and Broadway to the WFC was of special concern since four projects would be working along this corridor.

One significant difference between the GEIS for the WTC Memorial and Redevelopment Plan and the four transportation projects is the criteria used in determining the severity of the traffic impacts. The four transportation projects use criteria that were originally developed for the Route 9A Reconstruction Project FEIS in 1994 and subsequently used in the EIS for the East Side Access Project and the Second Avenue Subway. The GEIS for the WTC Memorial and Redevelopment Plan uses criteria from the New York *City Environmental Quality Review (CEQR) Technical Manual.* These criteria were specifically tailored for development projects are more stringent than the criteria used on the transportation projects. The rationale for the difference in these criteria relates to a project's intended purpose and use. Transportation projects generally strive to improve or enhance the capacity of an existing system. However, development projects generate person-trips that will use a transportation system. Thus, the WTC Memorial and Redevelopment Plan applied the more stringent criteria since it would generate trips to Lower Manhattan, whereas the other recovery projects would enhance the area's transportation infrastructure. While the number of severely impacted intersections may differ between these two approaches, the need for a comprehensive construction and traffic management plan has been agreed to by the project sponsors.

Air Quality and Noise and Vibration

For the noise and air quality analysis, the project sponsors agreed upon the set of emission levels to be used for both the on-road and non-road equipment. As part of this analysis, the project sponsors reached agreement with respect to the effectiveness of the EPCs on reducing air pollutant emissions from certain pieces of construction equipment. Subsequent to the publication of the DEIS for the Permanent WTC PATH Terminal, PANYNJ and MTA/NYCT coordinated to further their commitments beyond the original EPCs in order to lower emissions of particulate matter, which was determined to be the critical pollutant.

Once emission levels were determined, each project sponsor performed the cumulative effects assessment in their respective area of potential effect. For example, due to its distance from the other projects, the analysis for South Ferry Terminal is not influenced much by other projects' construction in the critical analysis year. Therefore, in that document, the cumulative effects assessment for noise and air quality is almost entirely a result of the project itself. However, in the vicinity of the WTC site the cumulative effects of the projects are typically much greater than any individual project's effect. Though in some cases, a particular element of one project may highly influence the resultant cumulative effect.

The prediction methodologies for noise and air quality impact assessments were the same for the various projects. The same air quality emission (EPA's NONROAD, MOBILE6.2 and AP-42) and dispersion models (CAL3QHCR and ISC3) were employed for each project's cumulative

assessment. Similarly, for the noise impact assessment, roadway noise was predicted using the proportional method based on guidance from the *New York City Environmental Quality Review Technical Manual* for all projects. Each project also modeled the construction equipment using a simplified noise equation (from FTA's guidance manual) which sums each piece of equipment affecting sensitive receptors based on the agreed upon noise emission levels and hours of operation. Where the respective projects overlap the results are quite consistent.

The impact criteria for air quality were based on the NAAQS with the exception of $PM_{2.5}$ where the project sponsors employed New York City Department of Environmental Protection (NYCDEP) interim criteria.

For the noise analysis, the impact criteria are similar for the five projects but not exactly the same. The FSEIS for the Route 9A Project uses FHWA criteria for noise impacts while the transit projects use FTA's criteria. LMDC uses the FTA guidance with an additional assessment comparing noise increases to the criteria in the *New York CEQR Technical Manual.* The differences are relatively minor. FHWA uses a single definition of impact—maximum hourly noise levels (i.e., L_{eq}) should not exceed 85 dBA. FTA's criteria are more detailed and use three land use (only two apply in the area, residential and commercial) and two distinct time averaging periods (an eight-hour average and a 30-day average). For the eight-hour average, the criteria for residential and commercial land uses are 80 and 85 dBA, respectively. For the 30-day average, the criteria are 75 and 80 dBA. However, in urban areas with very high ambient noise levels, such as the project sites, the FTA guidance recommends using an increase in Ldn of 10 dBA over existing noise levels as the exceedance criterion. The net results for each project's cumulative assessment are, therefore, essentially the same with respect to the predicted noise levels and the need for mitigation.

Cultural Resources

For cultural resources the cumulative assessment considered effects on both historic structures and archaeological resources pursuant to Section 106 of the National Historic Preservation Act. For most historic structures in the vicinity of the project sites, the assessment focused on issues related to potential damage from construction-related ground-borne vibrations. For each project the area of potential effect from its construction activities was determined and shared among the sponsors. This enabled each sponsor to consider the effects of the other project's construction on buildings that may be affected by their own project. The sponsors have developed a map illustrating all of the potential ground-borne vibration effects from the projects, structures of concern, and the overlap between the various projects.

However, for the WTC site itself, this cumulative effects assessment considers both direct and indirect effects during and after the critical construction year. A coordinated assessment was undertaken by FTA, FHWA, LMDC, PANYNJ, and NYSDOT with regard to the eligibility of the WTC site. In a joint Determination of Eligibility issued in March 2004, FTA, FHWA, and LMDC determined the WTC site eligible for listing on the National Register of Historic Places. The environmental documents prepared for the Lower Manhattan Recovery Projects were consistent in noting the Site's eligibility although the determination of potential effects varies with each project. Each of the project sponsors has been and continues to coordinate with SHPO and the consulting parties, pursuant to the Section 106 Process regarding their respective potential effects to the site. LMDC and NYSDOT identified potential adverse effects with respect to the WTC site and have prepared and executed Programmatic Agreements that will guide the design and construction of their projects with respect to their potential impacts. FTA and PANYNJ have executed a Memorandum of Agreement to minimize and mitigate the

adverse effect from the construction and operation of the Preferred Alternative. The Fulton Street Transit Center and South Ferry Terminal Projects would not have an adverse impact on the WTC site.

The analysis of potential effects to historic resources considers the cumulative impacts and cumulative mitigation measures of the Lower Manhattan Recovery Projects on the historic resources within the Area of Potential Effect for the Permanent WTC PATH Terminal. The Preferred Alternative was determined to have an adverse effect.

For archaeological resources the cumulative effects analysis has been based on the data developed among project sponsors and agreed upon with SHPO. There are two areas of known or potential archaeological sensitivity within the Permanent WTC PATH Terminal's APE. The Hudson River Bulkhead (State and National Register-eligible) has been declared historic from Battery Place to 59th Street. Portions of the Bulkhead are visible, but it is buried in the vicinity of the WTC site. Therefore, it is considered an archaeological resource for purposes of these analyses (see Chapter 6, "Cultural Resources"). There is also potential for archaeological sensitivity on the eastern portion ("east bathtub") of the WTC site; which is also considered in this analysis.

Economic Conditions

Generally, the cumulative effects on local businesses in the environmental documents have been mostly qualitative. While the cumulative traffic impact assessment has been quantified, the specifics of the construction and traffic management plans have yet to be developed. Maintenance of access to businesses, whether for deliveries or customers, requires a level of detail that is not available without further engineering design. For example, the air quality and noise analysis has been conducted assuming that certain pieces of equipment are in located in a general area for several months. However, to develop the actual Maintenance and Protection of Traffic Plans (MPT), which would illustrate how access would be maintained to a specific building, requires much more specific details. Therefore, the cumulative assessment has been focusing on the general areas of concern (which streets, curbside lanes and block faces are affected) and the commitment to further develop measures to avoid or minimize adverse effects.

CUMULATIVE CONSTRUCTION ANALYSIS FRAMEWORK

As noted in Chapter 3, "Construction Methods and Materials," the construction schedule for the Permanent WTC PATH Terminal has been delayed and extended as compared to the analysis presented in the DEIS. Similarly, the schedules for the World Trade Center Memorial and Redevelopment Plan, and Route 9A have been delayed.

In April 2005, LMDC released the *World Trade Center Memorial and Redevelopment Plan Environmental Assessment for Proposed Refinements*, which reviews the analysis results from the *World Trade Center Memorial and Redevelopment Plan FGEIS* in light of recent changes to the WTC Master Plan, including its construction schedule. This document included a revised construction impacts assessment to determine if new impacts are predicted and concluded that their impacts would be similar to the analysis presented in the FGEIS.

The revised construction analysis showed that LMDC's construction schedule is delayed and that its construction is not likely to peak until 2007 or 2008. Given similar delays in the schedules for the Permanent WTC PATH Terminal and the Route 9A Project, the cumulative construction in Lower Manhattan is also not likely to peak until 2007 or 2008. However, because the construction of the South Ferry Terminal and the Fulton Street Transit Center would peak

early, the overall level of activity in 2007 is expected to be lower than was projected in the Permanent WTC PATH Terminal DEIS.

The cumulative effects analysis in the DEIS assumed construction of one or more of the Lower Manhattan Recovery Projects would begin in 2004 and that activities would peak in 2006. This analysis assumed a more fast-tracked approach for these projects. Therefore, the assumptions in the DEIS regarding construction scheduling and phasing represent higher peak daily traffic, noise, vibrations, and air pollutant emissions than would occur under the revised construction schedules. Furthermore, the mitigation measures developed with respect to these maximum predicted levels would be even more effective under the less aggressive construction schedules.

The construction period analysis presented below describes both the cumulative construction schedule developed for 2006, which considers the peak for all of the Lower Manhattan Recovery Projects. Following the detailed analysis is a qualitative description of anticipated changes with the refinement of construction schedules occurred following the Permanent WTC PATH Terminal DEIS.

Lower Manhattan Recovery Projects

The federal government is sponsoring five major Lower Manhattan Recovery Projects: Permanent WTC PATH Terminal; WTC Memorial and Redevelopment Plan; Fulton Street Transit Center; South Ferry Terminal; and Route 9A Project (see Figure 5-1). These projects are briefly described below along with the construction work that is expected to occur in the peak analysis year.

WTC Memorial and Redevelopment Plan (Figure 15-1, Reference No. 1)

Rebuilding of the WTC site would provide for the construction of a Memorial and memorial-related museum and cultural facilities, up to 10 million square feet of commercial office space, up to 1 million square feet of retail space, up to 1 million square feet of conference center and hotel facilities, new open space, and infrastructure improvements, including loading and parking facilities, advanced security systems, and new and reconstructed streets. For this cumulative effects analysis, it has been assumed that LMDC would pursue its "Proposed Action" alternative as presented in the *World Trade Center Memorial and Redevelopment Plan Final Generic Environmental Impact Statement.*

The rebuilding of the WTC would take place over approximately 11 years, from 2004 to 2015. For this analysis the following activities were assumed to occur in the peak construction year:

- Demolition of Hudson and Manhattan (H&M) Terminal and excavation of East Bathtub: This task involves the removal of existing structures between Church Street and the 1 and 9 line on the eastern portion of the WTC site to form new basement levels for the complex. Once the existing structures have been demolished and removed, a new slurry wall would be constructed and work would proceed on the basement levels of the future WTC towers. To maintain temporary WTC PATH service, the East Bathtub would be constructed in two zones: northeast and southeast. As excavation of these zones is completed and as additional access can be provided to the temporary WTC PATH station, the spoils beneath the station itself would be removed to complete the excavation of the East Bathtub.

  Subsequent to the publication of the DEIS, PANYNJ determined that portions of the east bathtub excavation, including demolition of the H&M Terminal, will be undertaken as part the Preferred Alternative for the Permanent WTC PATH Terminal (see Chapter 2, "Project Alternatives"). Excavation of some portions of the east bathtub could also be undertaken by

LMDC for the WTC Memorial and Redevelopment Plan, depending on the timing of this project and the Permanent WTC PATH Terminal. Although the scope of excavation to be undertaken by LMDC and/or PANYNJ is not certain at this time, the cumulative effect would not change. Therefore, the east bathtub excavation has been retained here as part of the cumulative construction analysis framework.

- WTC Concourse and Freedom Tower foundations: Work within the northwest quadrant of the WTC site, would include the construction of sub-grade concourses and retail as well as Freedom Tower (Tower 1) of the WTC complex. The construction of Freedom Tower is expected to follow typical skyscraper methods of construction. This would involve the construction of several floors of the tower at a given time. As the skeleton of the building moves upward, facades and interior work is conducted on lower floors. This process is repeated until top out is achieved, after which, finishing work proceeds throughout the building.
- Towers 2, 3, and 4 foundation and below grade retail: Upon completion of the East Bathtub foundations for Towers 2, 3, and 4 would be constructed. This would include preparation of spaces for below-grade retail and servicing areas, construction of concourses, and preparation of the bases for the eventual construction of the office towers.
- East Bathtub above grade retail: As the bases of the office towers within the East Bathtub are completed, work would begin on the above-grade retail levels.

Elsewhere on the site it is assumed that the expansion of the bathtub south of Liberty Street would have begun, and the sub-grade build out of that space would continue. The construction of the Memorial itself, and associated cultural and open spaces, would also commence.

Route 9A Project (Figure 15-1, Reference No. 2)

NYSDOT proposes to reconstruct Route 9A immediately to the west of the WTC site between Barclay and Albany Streets. NYSDOT is currently considering three alternatives for the reconstruction of Route 9A. A No Action Alternative would rehabilitate the existing roadway, which was reconstructed following September 11, 2001. An at-grade alternative would restore the roadway to its pre-September 11, 2001 condition with modifications to accommodate the future uses on the WTC site. The third alternative calls for approximately 75 percent of vehicular traffic to be re-routed through a short, sub-grade bypass and improve at-grade pedestrian connections between the WTC site and Battery Park City (BPC). The construction of this bypass includes the requirement to maintain access to the WTC site with four traffic lanes throughout the construction of the project. For this cumulative effects analysis, the short-bypass alternative was assumed.

For the purposes of this analysis, the Route 9A short bypass has been assumed since it would result in the highest level of construction activity along Route 9A, as compared to other alternatives, and the greatest potential for construction impacts. The project has been disaggregated into four construction stages as follows:

- Stage I; Construct temporary north and south roadways adjacent to the site of the proposed sub-grade bypass. This activity is expected to take around 6 months.
- Stage II; Construct the southbound lanes of the sub-grade bypass.

- Stage III; Construct the northbound lanes of the sub-grade bypass. Upon completion of the southbound lanes, traffic would be re-routed to create a clear zone for the construction of the northbound lanes.
- Stage IV; Surface and Tunnel Finishes. As the bypass is complete, permanent tunnel lining must be installed, and the local road surfaces reinstated at street level.

In the peak construction year for this impact assessment, Stage II would be under construction. The proposed bypass would be located in fill beneath the groundwater table. As such, the proposed structure is required to provide a contiguous hydrostatic barrier to prevent the ingress of water into the sub-grade roadway. For the purposes of assessment of environmental impacts, it is assumed that a slurry wall method of site retention would be employed. Slurry walls would be built first and then excavation and tunnel construction would proceed. The slurry wall would be excavated to bedrock to limit the drawdown of groundwater and to prevent the intrusion of Hudson River water into the excavation.

Construction of the slurry walls would be from within the Stage II Work Zone. Six traffic lanes would be maintained during the duration of this stage for the peak traffic periods. After the slurry wall is complete, the excavation for the southbound bypass tunnel would be performed. The entire width between slurry walls would be excavated to the proposed invert of the sub-grade for the tunnel. Additional excavation would occur in the location of the Preferred Alternative's Route 9A concourse. Excavated spoils would be removed from the site by dump truck following the proposed truck routes.

NYSDOT is also undertaking streetscape improvements for the portion of Route 9A south of Albany Street. This project, referred to as the Route 9A Promenade South, is being studied and designed independent of the proposed improvements in the vicinity of the WTC site. The construction of the Promenade South began in September 2004 with anticipated completion in early 2006. Since, the Promenade South would be finished before the peak construction year for the Preferred Alternative, it is not considered as part of the construction cumulative effects analysis presented below.

Fulton Street Transit Center (Figure 15-1, Reference No. 4)

This cumulative effects analysis of the Fulton Street Transit Center assumes that MTA/NYCT would pursue Alternative 10 as presented in the *Fulton Street Transit Center Final Environmental Impact Statement*. Similar to the above projects, the engineering is ongoing. However, for descriptive purpose, the project has been disaggregated into five components as follows:

- Element 1, Dey Street Passageway: This element would include the site preparation for and construction of the passageway beneath Dey Street from Broadway and Church Street linking the 4 and 5 line with the R and W line. The passageway would be constructed with cut and cover methods. Including utility relocation, passageway construction, and street reconstruction, this element has a 24-month duration.
- Element 2: Entry Facility: This element includes the demolition of existing structures on the east side of Broadway between Fulton and John Streets, site preparation, foundations, and above-grade construction of the new entry facility to the Fulton Street Transit Center. This element has a duration of 27 months.

- Element 3: A/C Mezzanine: This element includes the extension and widening of the A and C line mezzanine and includes slurry wall construction and utility relocation. The total duration of this element is 26 months.
- Element 4, Underpasses: This includes the construction of concourses beneath the R and W and 4 and 5 subway tracks to link the Dey Street Underpass with the WTC site and the new Entry Building east of Broadway. Both underpasses would require approximately 6 months for construction.
- Element 5, Other station improvements: This element includes rehabilitation of platforms and station elements on the 4 and 5, 2 and 3, and J, M and Z lines; new access to the 4 and 5, 2 and 3, and A and C lines; and a new below-grade connection between the Cortlandt Street (R and W) and WTC (E) stations. Portions of Element 5 would be undertaken throughout the duration of the Fulton Street Transit Center project.

In the peak construction year for this impact assessment, components of all elements may be under construction. The following describes the major activities included in this cumulative effects analysis.

- Tunneling For Underpasses. The current Transit Center conceptual design locates a concourse structure directly beneath the existing R and W line at Church Street and beneath the existing 4 and 5 line at Broadway. In addition, it is intended that the 4 and 5 line northbound platform be widened beneath the east side of Broadway. In order to maintain traffic on Broadway and Church Street, and to limit disruption to subway service, the tunneling operation would most likely require an incremental underpinning sequence of adjoining structures along the east side of Broadway between Fulton and John Streets, in conjunction with careful monitoring of vibration and subway track movement.
- Concourse Construction under Dey Street. The rock strata elevation below Dey Street lies beneath the proposed depth of excavation. Consequently, it is probable that the concourse would be constructed using "cut and cover" construction methods.
- Widening of A/C Line Mezzanine. The A/C line mezzanine would be widened and reconstructed using a "top-down" sequential cut and cover sequence similar to the concourse construction at Dey Street. While the amount of actual required volume of excavation is far less than that required for the Dey Street concourse, the A/C line mezzanine widening is complicated by the need to maintain operation of the A/C line platforms. In addition, the structure of the rail tunnel itself is extremely sensitive to reductions and increases of overburden stress applied to the modular tunnel rings.

Construction of this project would require staging areas that would be closed to pedestrian and vehicular traffic for the duration of the relevant construction activity. The following staging areas were assumed for this analysis:

- Fulton Street: One lane and the southern sidewalk would be reserved for truck parking and staging throughout the construction period for a distance of approximately 180 feet east of Broadway to the eastern extent of the FSTC site. The remainder of Fulton Street between Broadway and Nassau Street would be temporarily closed to vehicular traffic for the duration of the mezzanine widening. Lanes would be open for emergency traffic and deliveries, but through traffic would not be permitted.

- Dey Street: It is anticipated that full closure of Dey Street from Church Street to Broadway and sequential closure of entire segments of the north and south sidewalks would be necessary for the duration of construction. Pedestrian access would be restricted to a five-foot egress sidewalk on the north and south curbsides. Temporary track loading areas would be established on both ends of the street. A vehicle lane for emergency access and essential local deliveries would be maintained.
- John Street: Under the alternative considered for this cumulative impacts assessment, lane and sidewalk closures would not be required on John Street.
- Church Street: The eastern travel lane and sidewalk would be closed at the intersection with Dey Street and between Fulton and Dey Streets during the period of the Dey Street passageway construction. In addition, the western lane and sidewalk would need to be closed during construction of the R and W connection.
- Broadway: It is anticipated that one eastern lane and the eastern sidewalk would be closed from Fulton Street to John Street. It is expected that the sidewalk would be used for truck and equipment parking and that pedestrians would be re-routed onto the eastern traffic lane during this period. The construction of the 4 and 5 line underpass stairs at 195 Broadway would also require the closure of the entire western sidewalk of Broadway. The construction of the Dey Street underpass would also require the temporary closure of Dey Street at Broadway.
- Nassau, Dutch, and William Streets: Construction of certain elements of the FSTC would involve temporary closure of vehicle lanes and sidewalks along Nassau, Dutch, and William Streets.
- Intersection of Maiden Lane, Cortlandt Street, and Broadway: All four corners, sidewalks, and travel lanes would be subject to intermittent closure with construction of the 4 and 5 line mezzanine.

South Ferry Terminal (Figure 15-1, Reference No. 5)

The South Ferry Terminal would be constructed generally within the limits of Peter Minuit Plaza, Battery Park, and immediately north of Whitehall Ferry Terminal. Street preparation work for the South Ferry Terminal under Peter Minuit Plaza would occur first. Construction of the approach tunnels, including underpinning of the existing 1 and 9 loop track and the 4 and 5 subway tunnels in the eastern edge of Battery Park would occur next. Terminal construction would occur next and the bellmouth and fan plant construction would follow. Construction of the bellmouth would require reconstruction of about 275 feet of existing subway tunnel. The reconstruction would require demolition of portions of the subway roof and sidewalls. Finishing work would be ongoing during the project's final phase and would occur underground.

The cut and cover construction of the approach tunnels for the South Ferry Terminal would require the demolition and reconstruction of Battery Place near its intersection with Greenwich Street. MTA/NYCT, in cooperation with NYSDOT, would complete the portions of the Route 9A Promenade South between Route 9A and State Street as part of the South Ferry Terminal project. This work would occur following the construction of the bellmouth approach tunnels. MTA/NYCT and NYSDOT would also share staging areas in the vicinity of Battery Place to reduce the off-site impacts of their construction projects.

In the peak construction year for this assessment, the following elements were assumed to be under construction.

- Cut and cover tunneling operations;
- R and W Whitehall Station connection to South Ferry Station;
- Underpin of 1 and 9 line and 4 and 5 line for new station construction;
- Bellmouth construction; and
- Ventilation plant construction.

Other Lower Manhattan Projects

Lower Manhattan Street Reconstruction Program

The New York City Department of Design and Construction (NYCDDC) is undertaking an aggressive program to reconstruct the majority of local streets in Lower Manhattan. NYCDDC has prepared a preliminary phasing plan for this program, which covers the area south of Canal Street between the Hudson and East Rivers. The extent of street reconstruction varies depending on the type of roadway, its history of previous repairs, and the level of subsequent damage. In some cases streets would be repaved, but other streets would be fully reconstructed, including utility relocation, sidewalk reconstruction, and new pavement. Based on NYCDDC's preliminary program, the following streets may be reconstructed concurrent with the peak activity for the Preferred Alternative:

- Canal Street from Hudson Street to Bowery Street;
- Worth Street from Hudson Street to Park Row;
- Greenwich Street from Chambers Street to Barclay Street;
- West Broadway from Vesey Street to Chambers Street;
- Church Street and Trinity Place from Chambers Street to Morris Street;
- Barclay Street from Route 9A to West Broadway;
- Vesey Street from Route 9A to Broadway;
- Liberty Street from Route 9A to Broadway;
- Cedar Street from Route 9A to Washington Street;
- Washington Street from Liberty Street to Cedar Street;
- Washington Street from Vesey Street to Barclay Street;
- Fulton Street from Church Street to South Street Viaduct;
- Frankfort and Dover Streets from Park Row to South Street Viaduct;
- Dey Street from Church Street to Broadway, and;
- South Street Viaduct from Whitehall Street to Brooklyn Bridge.

It is assumed that the street reconstruction program would be fully coordinated with the Lower Manhattan Recovery Projects such that the rehabilitation of streets in the vicinity of the WTC site would be postponed until the major construction efforts at the site were fully or nearly completed. This coordination would avert damage from WTC and PATH construction to already reconstructed roadways. However, given the aggressive timeline for this program, it is anticipated that some street reconstructions would be underway during the construction period of the Preferred Alternative, but these activities are expected to be on a scale and at a pace similar to what was underway at the time of the existing conditions surveys for this project. Since the street reconstruction program is not anticipated to occur in the immediate vicinity of the WTC site during the construction period for the Preferred Alternative, but would occur at other locations in Lower Manhattan, it has been considered as part of the background conditions for this cumulative effects analysis.

Private Development Projects

Based on the analysis presented in Chapter 4, "Land Use, Neighborhood Character, and Public Policy," four projects may have construction activities that overlap with construction of the Preferred Alternative. These projects are as follows:

- Washington Street Urban Renewal Area (WSURA) Site 5B, a 438-unit residential building with 229,595 square-feet (sf) of retail;
- BPC Site 23, an approximately 280,000-sf residential building with ground floor retail;
- BPC Site 24, an approximately 260,000-sf residential building with ground floor retail; and
- BPC Site 26, an approximately 2.3 million sf office building with ground floor retail.

To estimate the potential cumulative impacts of these private developments, assumptions were made regarding the type, length, and stages of construction that would be required. In New York City, new commercial and residential construction typically requires 18 to 24 months from site preparation to final fit-out. To conservatively estimate peak conditions, it was assumed that the private developments shown in Figure 15-1 would have an 18-month construction period.

It is assumed that the construction of these private developments would follow typical methods and procedures for new buildings in Lower Manhattan. The *New York Stock Exchange New Facility Final Environmental Impact Statement* (December 13, 2000), described proposed activities for its construction. These general assumptions were used for the private developments identified above.

The New York Stock Exchange FEIS identified four major phases of construction: demolition, foundations, tower core and shell construction, and interior construction. The estimated truck activity for each of theses phases is presented in Table 15-1.

Table 15-1
Typical Construction Period Truck Trip Generation for Private Developments

Phase	Peak Average Daily Truck Trips (One-Way)
Demolition	30
Foundations	30
Tower core and shell construction	10 to 15
Interior construction	25 to 35

Source: *New York Stock Exchange New Facility Final Environmental Impact Statement* (December 13, 2000)

The New York Stock Exchange expansion would have been a 600,000 square foot building, which is considerably larger than is proposed for BPC Site 23 and 24 and is comparable to WSURA Site 5B. Thus, these projects would generate a similar or lesser number of trucks than is presented in Table 15-1. BPC Site 26 would be four times the size of the proposed Stock Exchange and would, therefore, generates a larger number of trips than presented in Table 15-1.

BPC Sites 23, 24, 26, and WSURA Site 5B would not require building demolition. Thus their construction would begin with the foundations phase. Based on a typical construction schedule for a high-rise building and on currently planned completion dates, it is assumed that BPC Sites 23 and 24 and WSURA Site 5B would be either nearing the end of the tower core and shell phases or in the interior phase concurrent with peak construction activity for the Preferred Alternative. Thus, only BPC Site 26 would potentially be in foundation construction.

Construction Vehicles and Truck Routes

The assessment of post-September 11, 2001 traffic conditions, which is the basis for the construction period traffic networks, was developed using counts conducted in Spring and Fall of 2003. At the time of these counts, there were several ongoing construction projects in Lower Manhattan, including the temporary WTC PATH station, Battery Park City sites, 10 Liberty Street, and 2 Gold Street. Thus, the construction period traffic associated with these projects was included in the counts and the resultant baseline traffic networks. All of the projects under construction in 2003 would be completed by the critical analysis year, meaning that they would no longer generate construction vehicles; however, these vehicles were not removed from the future baseline traffic network. Since it is expected that the private development projects described above would generate an equivalent or lesser volume of construction vehicle trips in the critical analysis year as those projects included in the base counts, the trips associated with the private developments described above are considered as part of the future baseline traffic network.

Table 15-2 presents the total peak daily construction related truck trips that would be generated by each of the Lower Manhattan Recovery Projects in the critical analysis year. The sponsors of the federally-funded, Lower Manhattan Recovery Projects have coordinated to establish routes for individual site access during construction. As shown in Figure 15-2, trucks would enter and exit Lower Manhattan from six principal gateways: Holland Tunnel, Manhattan Bridge, Route 9A, Brooklyn-Battery Tunnel, Bowery, and Broadway/Avenue of the Americas. Within Lower Manhattan, these trucks would use Route 9A, Church Street, Broadway, Water Street, and South Street.

Table 15-2
Total Peak Daily Truck Trips Generated By Lower Manhattan Recovery Projects—Critical Analysis Year

Project	Heavy Truck Trips	Light Truck Trips	Total Truck Trips
WTC Memorial and Redevelopment Plan	694	310	1004
Permanent WTC PATH Terminal	172	64	236
Route 9A Project	320	48	368
Fulton Street Transit Center	262	70	332
South Ferry Terminal	150	98	248
Total	1,598	590	2,188

On-Site Equipment

For three of the Lower Manhattan Recovery Projects–WTC Memorial and Redevelopment Plan, Route 9A Project, and Fulton Street Transit Center—that would be constructed concurrent with and in the vicinity of the Project Site, an estimate of on-site equipment was made to support the cumulative analyses. Because construction of the South Ferry Terminal would occur approximately ½ mile south of the Project Site, no overlapping effects with South Ferry Terminal's on-site sources are expected. Thus, South Ferry's on-site equipment was not included in the cumulative effects analyses for air quality, noise and vibration, and cultural resources.

Appendix D presents the on-site equipment that would be generated by the Lower Manhattan Recovery Projects identified above for the peak construction year. The table lists the work zones and the types, numbers, and durations of use for each piece of equipment. Although the duration

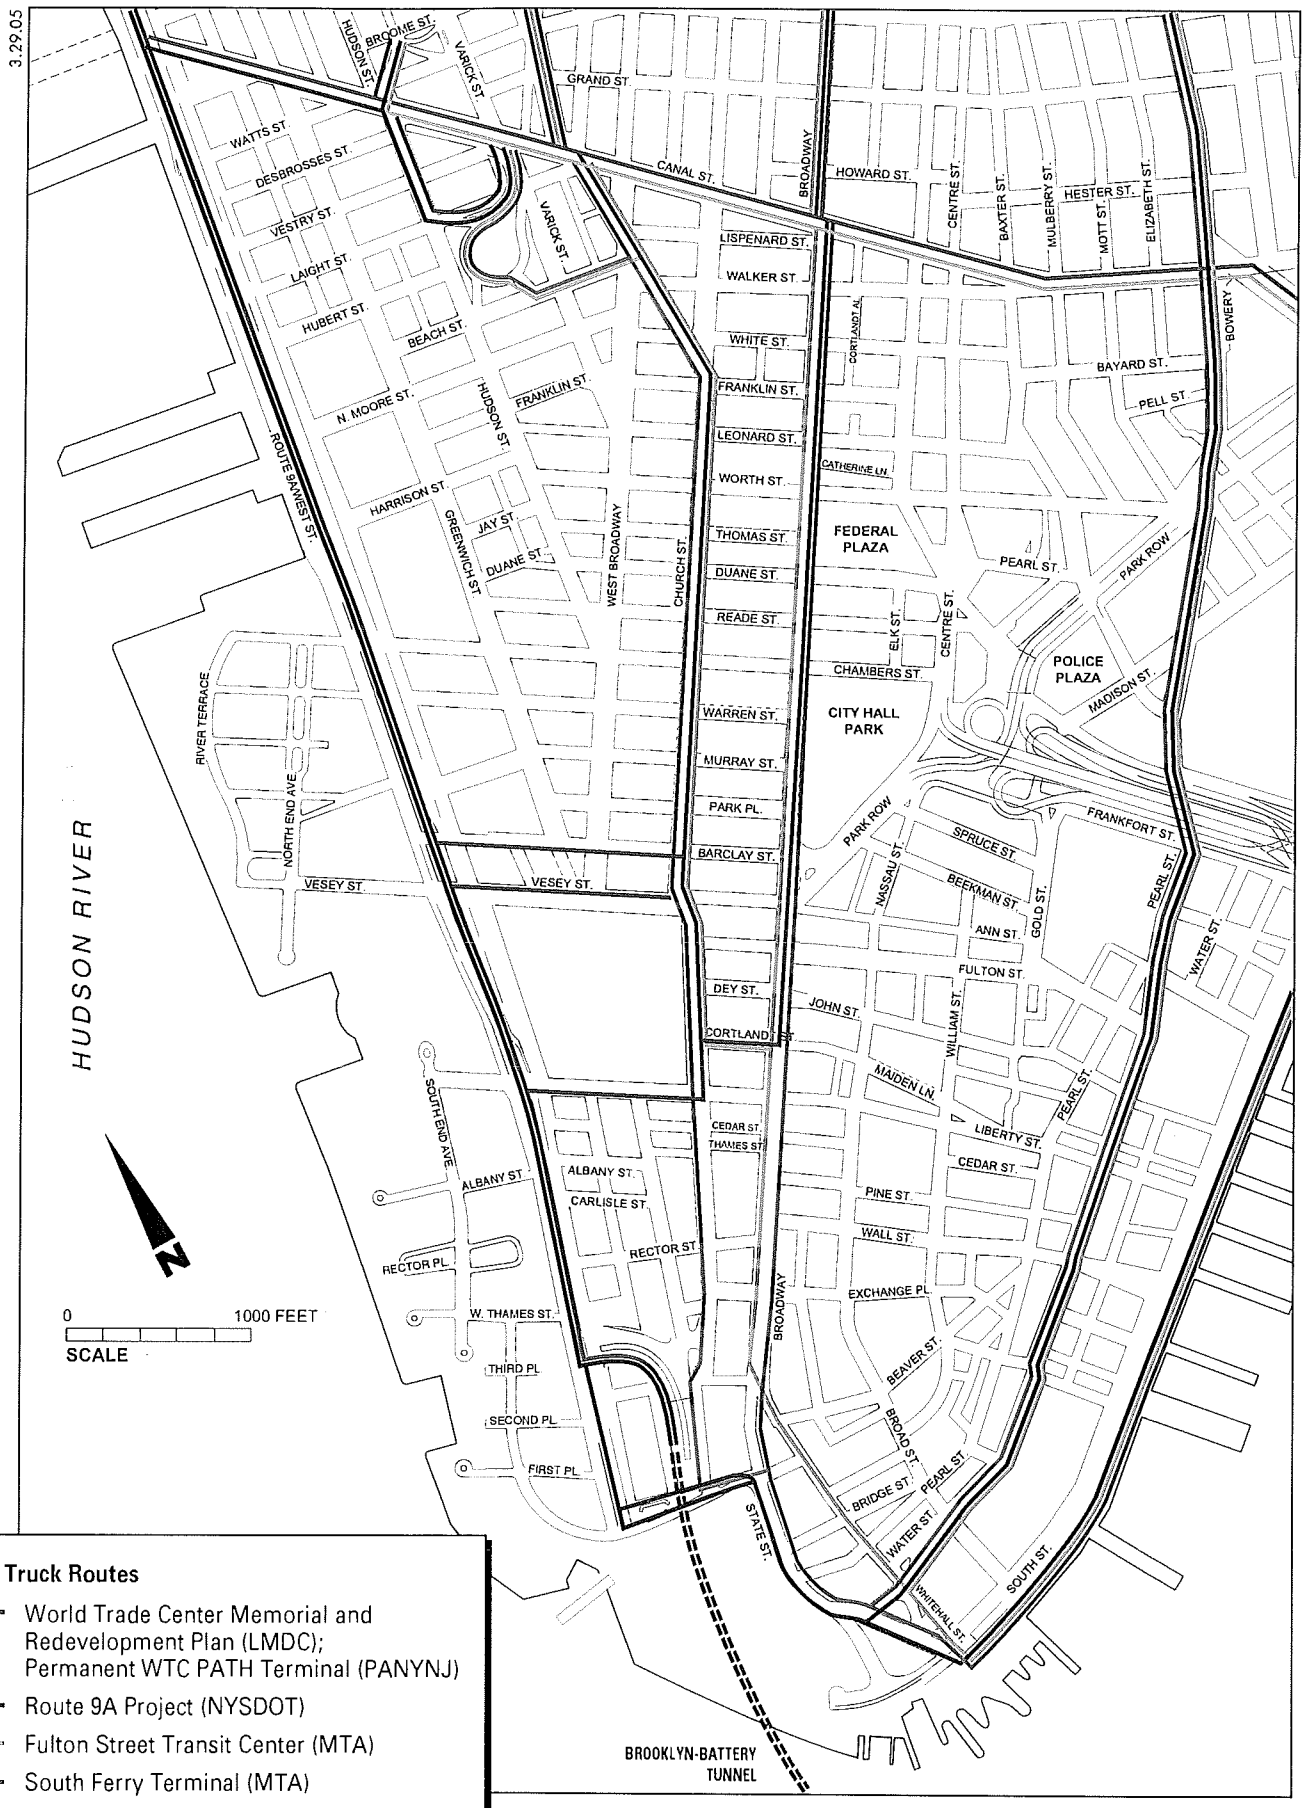

Figure 15-2

Truck Access Routes for the Lower Manhattan Recovery Projects

period (in months) is provided for summary purposes, many pieces of equipment may operate during only portions of the period. For additional details on the use of the equipment at each site, refer to Appendix D. The equipment that would be used for construction of the Preferred Alternative is presented in Chapter 3, "Construction Methods and Materials."

MITIGATION

Environmental Performance Commitments (EPCs)

The PANYNJ, LMDC, NYSDOT, and MTA/NYCT have developed a unified environmental analysis framework for the Lower Manhattan Transportation Recovery Projects, which is summarized in Chapter 2, "Project Alternatives." As part of this effort, these agencies developed EPCs that would be implemented during the construction of individual projects to avoid or minimize adverse effects to the environment. The EPCs and plans for their implementation are shown in Chapters 5, 6, 8, 9, and 10 of this FEIS for each of the five resource areas.

The EPCs that have been specified for the construction of the Preferred Alternative have been accounted for in the analysis of construction period impacts described in Chapters 4 through 14 of this EIS, where appropriate. These chapters also present mitigation measures to specifically address the potential construction-period impacts of the Preferred Alternative. However, in most cases and in particular with reference to the five resource areas identified above, the cumulative effect would result in more or greater impacts than would the Preferred Alternative alone. Thus, measures presented below to avert or minimize the adverse effects of the five Lower Manhattan Recovery Projects would also mitigate the project-specific impacts of the Preferred Alternative.

Similarly, the measures that have been committed to by the other agencies for their individual projects have been incorporated into the cumulative assessment of construction period impacts that follows below.

As part of the analysis, the project sponsors have and continue to consider the efficacy of the EPCs and additional mitigation. Leading up to the publication of this FEIS, extensive coordination and data sharing occurred among the agencies to develop a consistent set of specifications for the EPCs, as well as assumptions regarding their efficacy in reducing the adverse effects of construction. Most discussions centered on air pollution emission reduction measures, but also included traffic and noise reduction measures since the analysis shows a need to consider additional mitigation. Since the agencies were committing to measures beyond typical mitigation employed in the industry, it was necessary to make certain conservative assumptions about their effectiveness and availability. The details of these considerations are discussed in the technical analyses below. However, the result is that while the FEIS makes certain conservative assumptions, the project sponsors continue to meet to determine what can be realistically done to lower the predicted values.

Mitigation Measures under Consideration

Following the publication of the Draft EIS for the Permanent WTC PATH Terminal, the Lower Manhattan project sponsors continued to meet to further define the EPCs and their implementation. Areas of interest included:

- The development of a traffic management plan based on the current truck estimates;
- Development of a construction coordination plan focusing on individual stages of each project's plan;

- Application of diesel particulate filters (DPFs) to specific construction equipment with consideration for effectiveness and feasibility;
- Possible electrification of certain (e.g., welders, compressors, etc.) construction equipment to lessen the severity of potential adverse effects on concentrations of particulate matter and nitrogen dioxide; and
- Determining the critical equipment and activities that result in cumulative adverse noise effects at specific sensitive receptors. Based on the analysis to date, the project sponsors have now focused their concerns on specific locations.

This process has resulted in additional air quality and noise commitments as part of the Permanent WTC PATH Terminal, Fulton Street Transit Center, and South Ferry Terminal projects. The specific mitigation measures to be implemented are described in Section C, "Probable Construction Period Effects."

Also subsequent to the publication of the DEIS for the Permanent WTC PATH Terminal, FTA and PANYNJ executed a Memorandum of Agreement (MOA) pursuant to Section 106 of the National Historic Preservation Act. At the request of the Section 106 consulting parties, the MOA includes stipulations to coordinate potential cumulative effects to historic resources during and after construction. LMDC, NYSDOT, and MTA/NYCT were involved in developing these stipulations and have agreed to the process set forth in the executed MOA. Section C, "Probable Construction Period Effects," provides further information regarding the coordination commitments of the MOA.

Ongoing Coordination

The project sponsors have developed a framework for construction coordination, which includes establishing several working groups to address issues that have been identified in the individual environmental documents for the Lower Manhattan Recovery Projects and to implement the EPCs. While representatives of each of the sponsoring agencies are seated on each committee, one sponsor has been charged with coordinating the efforts of the individual working group. The following describes the construction working groups that have been formed and the principal goals and issues to be coordinated by the individual groups.

- Schedule Working Group: The schedule working group will coordinate construction schedules for the recovery projects. This group will develop and maintain and track a master construction schedule and will develop a geographic information system for Lower Manhattan to track construction activities.
- Logistics Working Group: The logistics working group will coordinate with the schedule working group to overlay construction activities, review phasing and staging plans, and to develop a master logistics plan for the recovery efforts. This group will seek opportunities to share construction facilities such as trailers, parking, and transport of workers and will coordinate the location and/or implementation of these shared facilities.
- Traffic Working Group: The traffic working group will develop the coordinated Traffic Management Plan for the Lower Manhattan Recovery Projects. This plan will compile the individual Maintenance and Protection of Traffic Plans for individual projects and will employ technologies to determine the best routes for delivery of goods and equipment and the removal of debris. This group will implement an Intelligent Transportation System (ITS)

system to communicate real time traffic information during the construction process and will coordinate the permitting of construction-related traffic issues (e.g., lane closures).

- Standards Working Group: The standards working group will coordinate the implementation of the EPCs through a consistent approach to construction contracts and specifications. The project sponsors have engaged the construction industry to determine the current and projected feasibility of the EPCs, and these efforts will be continued through the standards working group. The group will research available technologies and strive to implement appropriate advances to the extent possible during the construction process. Furthermore, this group will coordinate specifications for construction materials; will establish protocols for work hours, verification procedures, construction safety, cleanliness, signage, and public outreach; will develop requirements for construction contracts; and will centralize contract documents for the Lower Manhattan recovery efforts.

On November 22, 2004, New York State Governor George E. Pataki signed an Executive Order creating the Lower Manhattan Construction Command Center. The Command Center will administer the construction of project's within Lower Manhattan that either 1) have a construction value of more than $25 million; 2) require governmental actions or permits or; 3) require work within in a City or State street or highway. Of the projects noted above, the Command Center is expected to have oversight of the five Lower Manhattan Recovery Projects, the Route 9A Promenade South, Lower Manhattan Street Reconstruction, and the large private construction projects, including BPC Sties 24, 25, and 26, and the WSURA project.

The Command Center will coordinate community information, construction logistics, utility coordination, environmental compliance and safety, and diversity and equal opportunities in employment. The Command Center will be managed by an Executive Director to be appointed by the Governor and the Mayor of the City of New York. The Mayor will also appoint a Director of City Operations to act as a liaison between the Command Center and City officials. An Executive Committee, to be chaired by the Executive Director, will be appointed to facilitate communications between the Command Center, the Lower Manhattan Project Sponsors, and other key city and state departments and agencies.

As stated in the Executive Order, the functions of the Command Center will be:

- "Coordinating the work of the participants in the rebuilding process and ensuring that the construction in Lower Manhattan proceeds as scheduled by mediating conflicts in schedules and street and site access between construction projects, agencies, and the Lower Manhattan Community;"
- "Coordinating protocols, contract requirements and activities outside of individual project limits through planning on a daily basis throughout construction for government agencies, developers, construction managers, general contractors, and contractors;"
- "Coordinating construction projects to minimize inconvenience for residents, workers, pedestrians, vehicles, and commuters;"
- "Ensuring that the Lower Manhattan area remains neat, clean and orderly throughout construction;"
- "Communicating with residents, businesses, and the general public through a communications director working with each agency's communications and public outreach

personnel; providing a central focus on issues critical to the local community and the construction industry, by coordinating initiatives, public outreach, and information;" and

- "Utilizing technology to facilitate coordination of projects."

Governor Pataki appointed an Executive Director for the Command Center in February 2005, and the Command Center is working to formalize staff and structure. In the meantime, the Lower Manhattan project sponsors continue to coordinate through the vehicle of the Lower Manhattan Construction Coordination Group per their commitments within the Environmental Analysis Framework.

At this time, it is uncertain whether the role of the Lower Manhattan Construction Coordination Group will be assumed within the umbrella of the Command Center or if both will continue in tandem throughout the construction phase. However, one or both of these groups will ensure the coordination of construction issues between the Lower Manhattan project sponsors as their individual projects move forward.

APPROACH TO OPENING YEAR (2009) AND DESIGN YEAR (2025) EFFECTS

There are more differences among the projects with respect to the long-term assessments than what occurs with the short-term effects. In some ways, this is a result of the different types of projects and the need to focus on what each project may affect in the future and what is typically done in the environmental review process for that type of project. Some of the similarities and differences are discussed below.

While all five projects share a similar vision for the future development of Lower Manhattan and are based on the same future population, employment and land use projections, there are differences in how they are applied. The two MTA/NYCT projects use their own regional forecasting system to develop future (2025) transit ridership but the model does not include vehicular traffic forecasting. The supplemental DEIS (SDEIS) for Route 9A is more focused on roadway traffic and uses a model developed specifically for Manhattan's west side. It was developed for the 1994 *Route 9A Reconstruction FEIS*, focusing on travel patterns along Route 9A, and has been updated with the latest New York Metropolitan Transportation Council (NYMTC) forecasts. The GEIS for the WTC Memorial and Redevelopment Plan uses a methodology that is consistent with practices related to development projects in New York City. This methodology bases future traffic forecasts by adding known development projects to the baseline 2003 conditions. It does not consider modal or temporal shifts, or capacity constraints like the regional models used in the other projects. The different approaches result in differing future projections when comparing predicted traffic volumes at specific locations. However, in most cases these differences are not necessarily apparent since each project may or may not analyze the same set of circumstances as described below.

- The three transit projects would have a negligible effect on street traffic once completed and thus detailed traffic analysis for 2025 has not been conducted. The GEIS for the WTC Memorial and Redevelopment Plan analyzes traffic (and air quality) in 2009 and 2015 while the Route 9A Project provides estimates for 2007 and 2025, its opening and design year, respectively. The differences in predicted traffic volumes along Route 9A can be substantial. In addition, some street directions are different in the two EISs but the difference is more related to the timing of the analysis (and what was known at the time) rather than to any methodological difference.
- While the projections for vehicular traffic volumes in the EISs for Route 9A Project and the WTC Memorial and Redevelopment Plan differ, neither project predicts exceedances of the air quality standards as a result of cumulative effects. Furthermore, differences in predicted

noise levels are minor since it takes a doubling of traffic (which is much higher than the projected differences) to result in perceptible changes.

- Future transit ridership and pedestrian volumes in 2025 are the same in the projects since they were developed in concert by the sponsors of the transit projects (i.e., MTA/NYCT and PANYNJ). These volumes were then used in the GEIS for the WTC Memorial and Redevelopment Plan. The SDEIS for the Route 9A Project does not include a quantitative assessment of transit ridership, since this project would not directly alter existing transit service or induce new ridership. Because there would be changes in the pedestrian facilities along Route 9A, the SDEIS assesses pedestrians crossing Route 9A.

With the above in mind it should be noted that future traffic volumes along the major arterials in lower Manhattan (Route 9A, Church Street and Broadway) and their related effects on air quality and noise are more dependent upon the selection of an alternative for Route 9A than whether the FSTC or South Ferry Terminal are completed. This is also true for the Permanent WTC PATH Terminal, except under its No Action Alternative, which would have a measurable increase in traffic volumes on these roadways. Therefore, long-term future conditions of traffic, air quality, and noise are mostly a function of the commercial development of the WTC site and the selection of an alternative for the Route 9A Project.

Variations also exist for the Lower Manhattan Recovery Projects in terms of the underlying methodologies for long-term air quality and noise impacts since different agencies apply different evaluation criteria. However, these differences are inconsequential with respect to the Permanent WTC PATH Terminal FEIS since the Preferred Alternative's long-term effects on air quality are beneficial and since potential issues with respect to noise and vibration are related more to coordination with the design of the WTC Memorial and not to long-term impacts on existing and future residents and workers in Lower Manhattan.

As noted above, variations also exist in the evaluation of effects to the National and State Register-eligible WTC site. The Permanent WTC PATH Terminal DEIS identified a significant adverse impact on the site, and FTA and PANYNJ have an MOA executed to address these impacts. The Route 9A SDEIS and the World Trade Center Memorial and Redevelopment Plan FGEIS identify potential adverse effects; thus, these projects have executed Programmatic Agreements that will address effects if they are later determined to be adverse. Although the approach to identify these effects varies amongst the projects, the sponsors have agreed to stipulations, contained within the Permanent WTC PATH Terminal's executed MOA, to address cumulative effects on the WTC site. This commitment is described in more detail in Section C, "Probable Construction Period Effects."

C. PROBABLE CONSTRUCTION PERIOD EFFECTS

As described in this EIS, the No Action Alternative for a Permanent WTC PATH Terminal would not result in adverse impacts during the construction period. Thus, any cumulative adverse impacts in Lower Manhattan during this time would be attributed to other construction projects in the area. Thus, a construction period assessment for the No Action Alternative has not been addressed as part of this cumulative effects analysis.

ACCESS AND CIRCULATION

VEHICULAR TRAFFIC

Probable Impacts

The *WTC Memorial and Redevelopment Plan GEIS* contains a comprehensive examination of expected traffic conditions in the 2006 peak construction year for the combination of several major projects, including its own project's construction and that of the Fulton Street Transit Center, South Ferry Terminal, Route 9A Project, and the Permanent WTC PATH Terminal. All projects were closely coordinated with respect to construction year traffic projections and conditions. The information that follows was derived from that coordinated effort.

As described above, different traffic impact criteria were applied for the WTC Memorial and Redevelopment Plan and the Lower Manhattan Transportation Recovery Projects. The WTC Memorial and Redevelopment Plan used the *CEQR Technical Manual* guidance, which are more stringent and are typically applied to development projects that directly induce new vehicular traffic. These criteria are as follows:

- For a Level of Service (LOS) A, B, C condition, a project-generated increase in delay that results in mid-LOS D (45.0 seconds of delay) or worse is considered adverse.
- For a baseline LOS D condition, a project-generated increase of 5 seconds or more resulting in delays in excess of 45.0 seconds is considered adverse.
- For a baseline LOS E condition, a project-generated increase of 4 seconds or more of delay is considered adverse.
- For a baseline LOS F condition, a project-generated increase of 3 seconds or more of delay is considered adverse unless the baseline has more than 120.0 seconds of delay when a 1-second increase would be adverse.

To provide for consistency in this cumulative assessment, the CEQR impact criteria were used. It is expected that if the criteria described in Chapter 8, Section B, "Vehicular Traffic and Parking," had been used for this cumulative assessment, there would be fewer impact locations.

The analysis of cumulative traffic effects was conducted at a set of 24 intersections, 21 of which are signalized and three which are unsignalized. Overall, future conditions with construction of the above projects would create adverse traffic impacts at the following six intersections:

- Route 9A and Vesey Street (AM peak hour)
- Church Street and Chambers Street (AM and PM peak hours)
- Church Street and Barclay Street (AM peak hour)
- Church Street and Cortlandt Street (midday peak hour)
- Broadway and Canal Street (PM peak hour)
- Broadway and Worth Street (AM, midday, and PM peak hours)

Figure 15-3 shows the cumulative construction period truck trip generation for selected intersections in the vicinity of the Project Site. Table 15-3 shows delays and LOS for the vehicle movements that would be adversely impacted by cumulative construction based on analysis conducted for the *World Trade Center Memorial and Redevelopment Plan DGEIS.* Appendix C shows the delays and LOS results for all of the analysis locations.

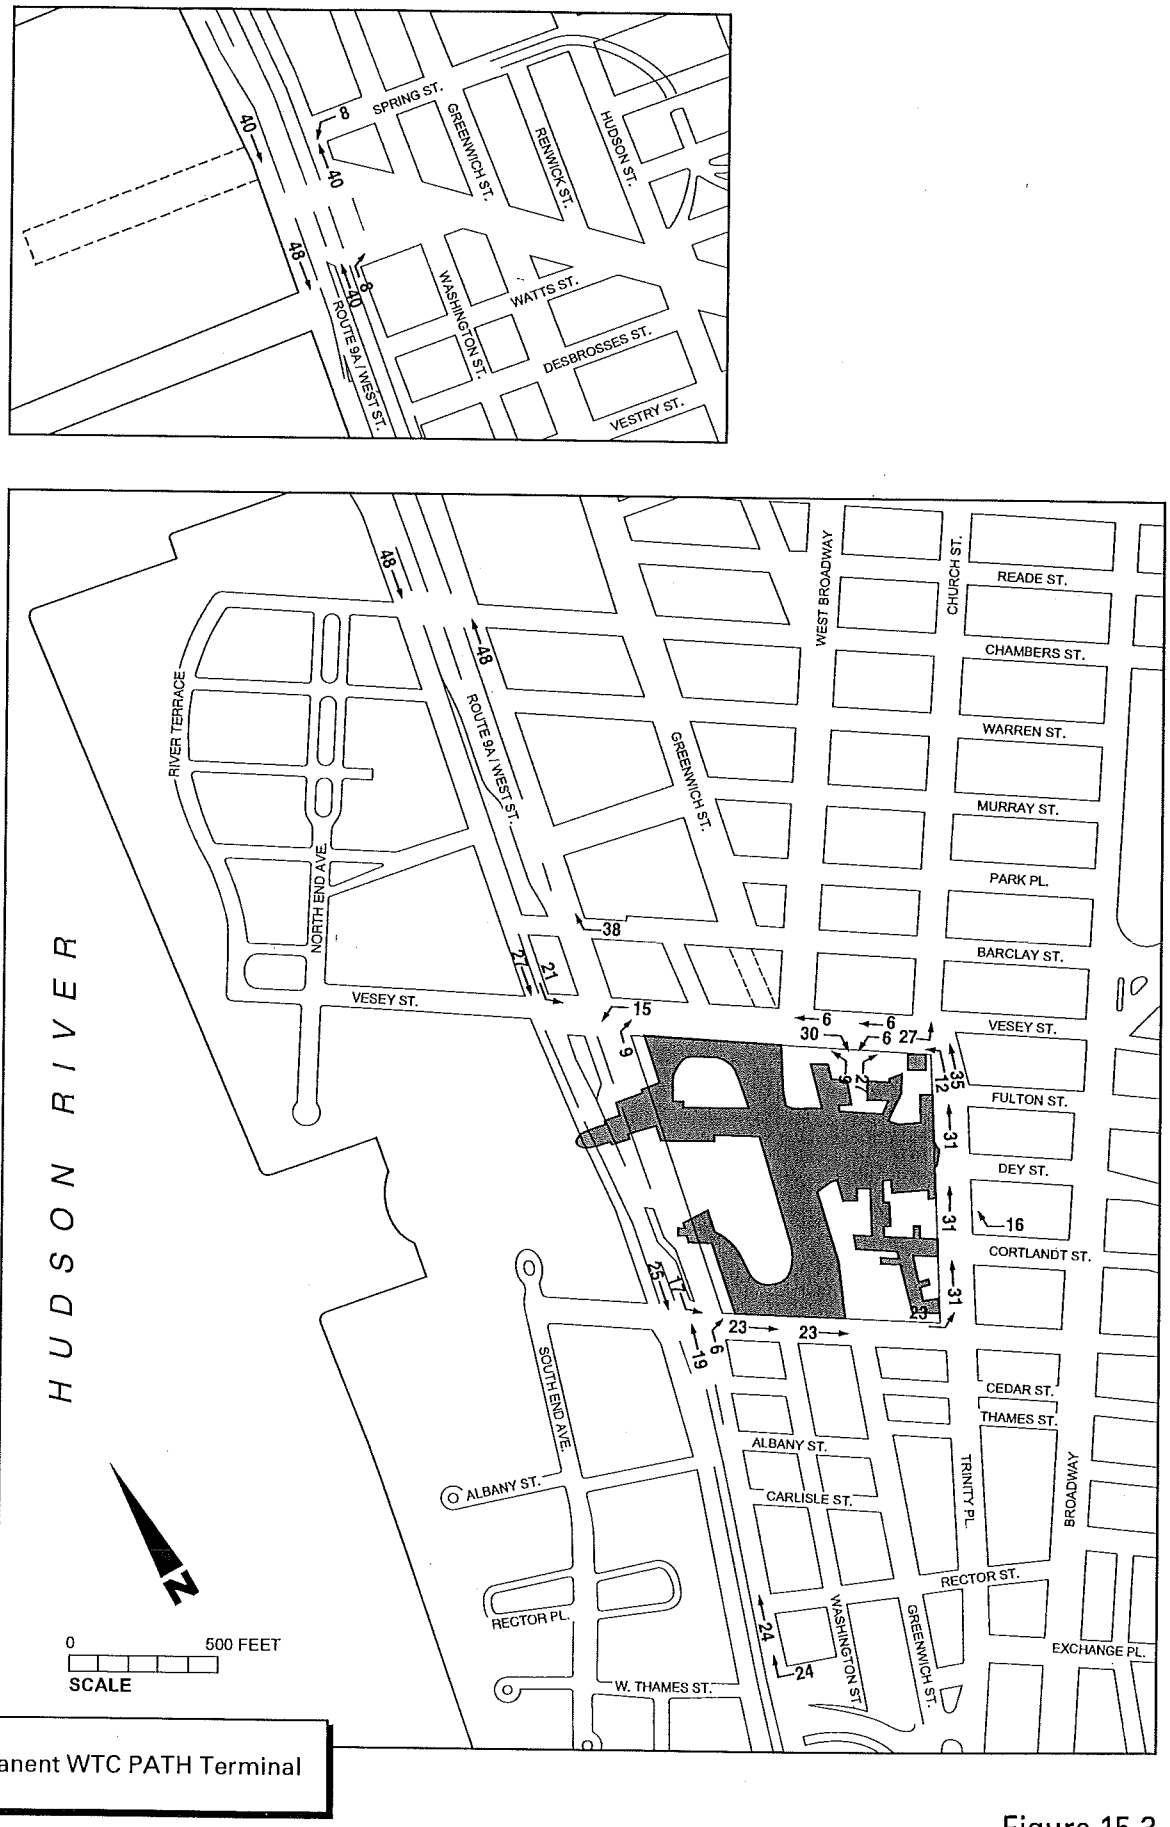

Figure 15-3

Cumulative Peak Hourly Construction Period Truck Trips

Table 15-3
2006 Construction Period: Summary of Peak Hour Adverse Impacts

Intersection	Peak Hour	Movement	Baseline LOS (Delay in seconds)	Cumulative Increase in Delay (seconds)
Route 9A and Vesey Street	AM	Northbound Thru and Right-Turn	F (150.3)	1.0
Church St and Chambers Street	AM	Northbound Approach	F (169.6)	1.8
Church St and Chambers Street	PM	Northbound Approach	F (162.7)	1.4
Church St and Barclay Street	AM	Northbound Approach	D (47.5)	12.5
Church St and Cortlandt Street	MD	Westbound Approach	F (85.5)	3.6
Broadway and Canal Street	PM	Westbound de facto Left-Turn	F (96.1)	4.3
Broadway and Worth Street	AM	Southbound Approach	F (290.2)	2.6
Broadway and Worth Street	MD	Southbound Approach	F (245.1)	5.6
Broadway and Worth Street	PM	Southbound Approach	F (295.3)	2.6

Note: The baseline LOS reflects conditions from which impacts are evaluated. Refer to Appendix C for detailed information on the baseline and cumulative Levels of Service (LOS).

Mitigation

The mitigation of cumulative traffic effects of the various Lower Manhattan construction activities would also be a coordinated effort under the auspices of both NYSDOT and NYCDOT, since both agencies have jurisdiction over the affected roadways—NYSDOT with regard to Route 9A and NYCDOT with regard to all other streets in the area.

- At Route 9A and Vesey Street, the cumulative effects of all construction vehicles (82 in the peak traffic hours) would create an adverse traffic impact along northbound Route 9A by creating a future condition with an incremental delay of one second. The Preferred Alternative's construction would contribute an estimated 12 vehicles out of the 82 and would, therefore, not be the major contributor to the impact.
- At Church Street and Chambers Street, PATH construction would generate just one vehicle through the impacted northbound approach out of the total of 24 construction vehicles expected to pass through the intersection along northbound Church Street in the AM and PM peak hours, with an increase in intersection delay of 1 to 2 seconds.
- At Church Street and Barclay Street, PATH construction vehicles would generate 8 of the 62 construction vehicles expected, with the northbound Church Street approach to the intersection deteriorating from level of service (LOS) D to LOS E.
- At Church Street and Cortlandt Street, PATH would generate 5 of the 57 construction vehicles expected along westbound Cortlandt Street in the midday peak hour, with the westbound Cortlandt Street approach expected to deteriorate by 3.6 seconds within LOS F.
- At Broadway and Canal Street, PATH would generate 2 of the 35 construction vehicles that would create an adverse impact in the PM peak hour along westbound Canal Street.
- At Broadway and Worth Street, adverse impacts are expected in the AM, midday, and PM peak hours along southbound Broadway with 27 construction vehicles generated overall.

As noted above, the cumulative construction of the Lower Manhattan Recovery Projects would require mitigation measures. These measures would be incorporated in a coordinated Maintenance and Protection of Traffic (MPT) Plan. As described in the Route 9A Project SDEIS, NYSDOT would prepare this plan on behalf of the Lower Manhattan project sponsors through either the Command Center or the Lower Manhattan Construction Coordination Group, as appropriate. The MPT Plan would include input from PANYNJ, MTA/NYCT, LMDC, and NYCDOT and would specify measures to stage construction areas (e.g., lane and sidewalk closures) while providing measures for the circulation of traffic through Lower Manhattan (e.g., traffic diversions, parking restrictions, and signal timing adjustments).

Conditions with the Revised Schedules

The refinements to the Lower Manhattan Recovery Projects' schedules would slightly alter the findings presented above. The cumulative peak hour truck trips would be approximately 9 percent lower in the peak construction year under the refined schedules as compared to the analysis presented above. As a result, the projected traffic impact at Canal Street and Broadway would not occur. However, increases in background traffic growth, combined with cumulative construction vehicle trips would result in an impact at the intersection of Canal and Hudson Streets in the AM peak hour. This impact could be mitigated with signal timing adjustments, which would be incorporated into the coordinated Maintenance and Protection of Traffic (MPT) Plan for the Recovery Projects.

PEDESTRIAN CIRCULATION

Probable Impacts

During construction of the Preferred Alternative, there would be additional construction associated with planned development in Lower Manhattan. A cumulative analysis of construction-period pedestrian level of service was conducted and the results are shown in Table 15-4.

In most cases, crosswalks would operate at LOS D or better during the critical construction year, and there would be no change in LOS as compared to baseline conditions. However, there would be deterioration to LOS E conditions at the intersections of Church Street and Dey Street and at Church Street and Cortlandt Street in the AM and PM peak hours.

Mitigation

Although no additional locations would deteriorate to LOS F due to Cumulative Construction Period effects, conditions at some locations would deteriorate to LOS E as compared to the baseline. As described above, a MPT Plan will be prepared for the Lower Manhattan Recovery Projects. This plan will include measures to ensure that safe and efficient pedestrian access and circulation is maintained throughout the construction period. Measures that may be incorporated could include signal timing adjustments; protected pedestrian walkways, and crossing guards. It is anticipated that the MPT Plan would be administered by the Command Center or the Lower Manhattan Construction Coordination Group in coordination with NYSDOT, NYCDOT, PANYNJ, LMDC, and MTA/NYCT.

AIR QUALITY

The analysis of the potential cumulative air quality impacts of construction of the Preferred Alternative and the other Lower Manhattan Recovery Projects uses the methodology described in Chapter 9, "Air Quality." Additional information regarding air quality in the context of the aftermath of September 11, 2001; air quality standards and benchmarks for determining the significance of impacts; background pollutant levels; and general procedures for air quality modeling also appear in Chapter 9.

This cumulative air quality assessment was modified since publication of the DEIS to reflect mitigation commitments for the WTC Memorial and Redevelopment Plan as well as to describe both alternatives for the Route 9A Project. LMDC incorporated additional mitigation measures (e.g., electrification and diesel particle filters) in their ROD for the WTC Memorial and Redevelopment Plan. These measures were included in this cumulative effects analysis. Furthermore, analysis was prepared for both the at-grade and short bypass alternatives for Route 9A since construction methods for both Route 9A and PATH's east-west concourse would vary.

Since almost all construction equipment and trucks use diesel engines, the main pollutants of concern for local analysis are particulate matter, nitrogen dioxides, emitted as engine exhaust

and fugitive dust and analyzed as $PM_{2.5}$, PM_{10}, and NO_2. Neither onsite nor offsite parking would be provided for construction workers, other than for a few delivery vehicles; thus, most construction workers would arrive by public transportation. Therefore, no significant increase in light duty gas vehicle trips is expected. Since diesel engines emit very little carbon monoxide (CO) analysis of CO from construction engines on-site was not warranted. The combined impact of construction related traffic on intersections, which could potentially impact the running speeds or idling times of background traffic and the ensuing CO concentrations was analyzed. The diesel fuels used for on-road vehicles contain low concentrations of sulfur, and pursuant to the EPCs, the on-site non-road diesel construction engines would be using ultra low sulfur diesel (ULSD). Emissions of sulfur dioxide (SO_2) from the site are therefore not of concern.

The analysis of on-site sources for the Lower Manhattan Recovery Projects in the critical analysis year considered the numbers and types of equipment in each work zone at each of the sites; the period of use (e.g., days or months); the percentage of time it would be operated during the period; and the size of the equipment.* (See "On-Site Equipment" above and Appendix D for more information on the on-site and mobile sources assumed in the analysis.)

All diesel construction engines, excluding on-road trucks, would use ULSD. Furthermore, where practicable, engines larger than 50 horsepower (HP) would include emissions reduction measures to reduce emissions of PM and volatile organic compounds (VOCs). For the purpose of this analysis, it was assumed that PM emissions from all such engines would be reduced by 40 percent—the reduction achieved by using diesel oxidation catalysts (DOC). PM emissions may be reduced by 90 percent or higher in cases where diesel particle filters (DPF) would be used. (These reductions include a reduction of approximately 14 percent due to the use of ULSD, as compared to the baseline emissions using normal fuel.) Since it is uncertain at this time what emission reduction technologies would be most efficient with each equipment type, and since DOCs are more efficient at reducing VOC emissions, which are ozone precursors and are of regional concern, the EPCs provide the flexibility to utilize either DOC or DPF control technologies. Therefore, the minimum PM emissions reduction of DOCs was assumed for this analysis.

To predict average concentrations for the time periods corresponding to the appropriate standards and impact criteria, on-site emissions were modeled for two time periods: 24-hours for PM and annual averages for PM and NO_2. These emissions were based on the construction activity predicted for each of those time scales, as described above and in Appendix D. Typical daily activity emissions were calculated for the various phases averaged over the year to produce annual emission rates for each work zone. Peak day activity emissions were calculated for each phase, and the values calculated for the period with the highest total emissions from all work zones were used for the 24-hour emission rates. A detailed description of emission factors from the various models described above and total emission rates based on construction activities in each zone is presented in Appendix D.

Background annual average $PM_{2.5}$ concentrations in New York City currently exceed the NAAQS. Until the $PM_{2.5}$ NAAQS are fully implemented and NYSDEC adopts a State Implementation Plan covering $PM_{2.5}$, the assessment of potential impacts and mitigation regarding fine particulate matter has been conducted using the NYSDEC and New York City Department of Environmental Protection (NYCDEP) interim threshold criteria.

---

* Given its distance from the Permanent WTC PATH Terminal, the South Ferry Terminal was not included for the cumulative analysis of on-site equipment.

PROBABLE IMPACTS

On–Road Carbon Monoxide Analysis

Maximum predicted CO concentrations in the critical analysis year were predicted at two intersections along Route 9A, similar to the analysis for this project. These locations are of concern because of the high level of traffic currently using the roadway and the potential for construction vehicles to adversely affect traffic flow and thereby increase CO emissions at critical intersections. The analysis includes all construction vehicles from the five major Lower Manhattan Recovery Projects and total approximately 2,000 per day. Approximately, a third of the construction vehicles would use Route 9A to access the WTC, PATH, and Route 9A construction work areas. As shown in Table 15-5, maximum predicted 8–hour average CO concentrations would increase by 0.6 ppm over conditions without any activity from the five major projects. With that increase, total CO concentrations would still be well below the NAAQS.

Table 15-5
Critical Analysis Year: Maximum Predicted 8-Hour Average CO Concentrations

Site	Without Cumulative Construction	With Cumulative Construction
Route 9A and Liberty Street	5.1	5.7
Route 9A and Vesey Street	5.5	5.5
Note: National Ambient Air Quality Standard (NAAQS) for CO is 9 ppm.		

Particulate Matter and Nitrogen Dioxide Analyses

The highest predicted increase in pollutant concentrations from construction activity in the vicinity of the construction sites is presented in Table 15-6. The total predicted concentrations, including background levels and the increment from the projects, are presented in Table 15-7. The concentrations include both on–road sources and on–site construction activity emissions.

To illustrate the effects of the emissions from construction on ambient air quality in the vicinity of the project, isopleths (i.e., lines of equal concentration increases) were developed based on the results of the air quality dispersion modeling. Figures 15-4 through 15-13 show the increase in annual average PM_{10}, 24-hour average PM_{10}, annual average $PM_{2.5}$, 24-hour average $PM_{2.5}$ and annual average NO_2 concentrations from cumulative construction activity in the critical analysis year for both of the Route 9A alternatives.

Under the Route 9A short bypass alternative, the maximum increase in PM_{10} concentrations is projected to be 4.4 $\mu g/m^3$ and 86.5 $\mu g/m^3$ on an annual and 24-hour basis, respectively. When considered with background conditions, the total maximum PM_{10} concentrations would be 31.9 $\mu g/m^3$ and 146.9 $\mu g/m^3$ on an annual and 24-hour basis, respectively. Both the annual and 24-hour concentrations would be below the NAAQS. As shown in Figures 15-4 and 15-6, the maximum annual increase is predicted near the intersection of Route 9A and Vesey Street while the maximum 24-hour increase would be along the Route 9A bikeway adjacent to the World Financial Center. At residential receptors, the maximum increase would be significantly lower (17.1 $\mu g/m^3$ for the 24-hour period and 2.5 $\mu g/m^3$ on an annual basis).

Table 15–6
Highest Predicted Increase in Pollutant Concentrations from Cummulative Construction of the Lower Manhattan Recovery Projects in the Critical Analysis Year

Pollutant	Average Period	Receptor Type	Maximum Increase [µg/m^3] With Route 9A Short Bypass	Maximum Increase [µg/m^3] With Route 9A At Grade
NO_2	Annual	Highest of All Receptors	24.3**	21.5**
		Residential Buildings / Hotel	22.2**	21.5**
$PM_{2.5}$	24–hour	Highest of All Receptors	68.4*	82.5*
		Residential Buildings / Hotel	11.3*	11.4*
		Other Locations on Access Routes	0.4	0.4
	Annual	Local Highest of All Receptors	2.4*	2.4*
		Local Highest Residential / Hotel	1.8*	1.8*
		Local on Access Routes	0.17	0.17
		Neighborhood Scale	0.42*	0.38*
PM_{10}	24–hour	Highest of All Receptors	86.5	117.9
		Residential Buildings / Hotel	17.1	26.5
		Other Locations on Access Routes	4.5	4.5
	Annual	Highest of All Receptors	4.4	4.0
		Residential Buildings / Hotel	2.5	2.5
		Other Locations on Access Routes	1.4	1.4

Notes:
Interim guidance threshold levels for $PM_{2.5}$ are 5 µg/m^3 and 0.3 µg/m^3 for 24–hour and annual increases respectively, and 0.1 µg/m^3 for neighborhood scale annual average. For determination of adverse impacts, these values are applied in the absence of specific criteria.

* Indicates substantial adverse impact–exceeding the interim guidance thresholds.

** Substantial adverse impact due to high increment predicted where existing background concentrations are high—not exceeding NAAQS (see table 15–7).

	Annual	Highest of All Receptors	31.9	31.5
		Residential Buildings / Hotel	29.7	29.6
		Other Locations on Access Routes	28.8	28.8

Notes:

All total concentrations include calculated background contributions from local mobile sources, as well as measured regional background values as follows: NO_2—Annual average 72 µg/m³; $PM_{2.5}$—Annual average 17.1 µg/m³ (highest of 2000-2002 annual values); 24-hour average 44.0 µg/m³ (highest of the three 2nd highest 24-hour averages in 2000-2002); PM_{10}—Annual average 24 µg/m³; 24–hour average 50 µg/m³.

The NAAQS are as follows: NO_2—Annual = 100 µg/m³; $PM_{2.5}$—24–hour = 65 µg/m³ and Annual = 15 µg/m³; PM_{10}—24–hour = 150 µg/m³ and Annual = 50 µg/m³.

Cumulative and project–generated maximum concentrations may occur at a different time and/or location.

* Indicates predicted exceedance of new NAAQS for which the conformity process is not yet in effect.

** $PM_{2.5}$ annual average concentrations exceed the NAAQS in the existing background condition. See Table 15–5 for comparison with incremental thresholds.

Under the Route 9A at-grade alternative, the maximum increase in PM_{10} concentrations would be 117.9 µg/m³ on a 24-hour basis and 4.0 µg/m³ on an annual basis. These potential maximums could occur at the temporary bikeway along Route 9A (see Figures 15-5 and 15-7). As shown in Table 15-7, the maximum total 24–hour average PM_{10} concentration along the temporary bikeway could exceed the annual NAAQS under the at-grade alternative. However, this would only occur if peak construction occurs near that receptor when background levels actually reach 50 µg/m³. Increases at residential receptors would be significantly lower with a maximum of 26.5 µg/m³ and 2.5 µg/m³ on a 24-hour and annual basis, respectively.

Under the Route 9A short bypass alternative, the predicted increase in $PM_{2.5}$ concentrations in the immediate vicinity of the sites would be a maximum of 66.4 µg/m³ and 2.4 µg/m³ on a local 24-hour average and annual average basis, respectively. On a neighborhood scale, the maximum

annual increase would be 0.42 $\mu g/m^3$. These maximum predicted increases in $PM_{2.5}$ concentrations would exceed the interim guidance threshold values. As shown in Figures 15-8 and 15-10, the increase in $PM_{2.5}$ concentrations would exceed the 0.3 $\mu g/m^3$ annual and the 5 $\mu g/m^3$ 24–hour thresholds over a much larger area than shown previously for construction of the Preferred Alternative alone. The concentrations decrease rapidly with the distance from the sites, and no exceedance of the threshold values would be expected at a distance of approximately 1,300 feet from the sources.

Under the Route 9A at-grade alternative, the predicted increase in $PM_{2.5}$ concentrations in the immediate vicinity of the sites also exceed the interim guidance thresholds and would be a maximum of 82.5 $\mu g/m^3$ and 2.4 $\mu g/m^3$ on a local 24-hour average and annual average basis, respectively. On a neighborhood scale, the maximum annual increase would be 0.38 $\mu g/m^3$. However, similar to the short bypass alternative, the concentrations decrease rapidly with the distance from the sites, and no exceedance of the threshold values would be expected at a distance of approximately 1,300 feet from the sources (see Figures 15-9 and 15-11).

Without further mitigation, cumulative construction of the Lower Manhattan Recovery Projects would result in an adverse impact on $PM_{2.5}$ concentrations. However, the total $PM_{2.5}$ concentrations presented are conservative since they are based on the highest monitored level in the years 2000-2002. Based on the highest monitored annual average $PM_{2.5}$ concentration of 17.1 $\mu g/m^3$, the annual local $PM_{2.5}$ concentration could total a maximum of 20.5 $\mu g/m^3$, and the annual neighborhood scale $PM_{2.5}$ concentration could increase to 19.8 $\mu g/m^3$. It should be noted that the current annual measured background levels of $PM_{2.5}$ exceed the NAAQS of 15 $\mu g/m^3$.

Based on the highest measured 24-hour background concentration of 44 $\mu g/m^3$, the predicted 24-hour average $PM_{2.5}$ concentrations at locations immediately adjacent to the site could potentially exceed 129.5 $\mu g/m^3$ without further mitigation. As shown in Figure 15-10 and 15–11, these exceedances would not be expected at residential locations surrounding the WTC site, but would occur at two locations—along Route 9A and near the Fulton Street Transit Center.

The 24-hour average PM concentrations exhibit local maximums, reflecting specific wind directions and local activity; thus, they are much more influenced by a single activity that may produce higher short–term concentration increases. Annual average PM concentrations, however, are more uniform over the study area. This is expected, since over the long-term, the influence of wind directions and the scattering of construction equipment throughout the area would result in a more uniform distribution of the concentrations. In any event, these results indicate that additional mitigation is necessary to decrease concentrations of particulate matter beyond the 40 percent reduction assumed with the use of DOCs in order to minimize impacts and to ensure that 24–hour concentrations of $PM_{2.5}$ and PM_{10} do not exceed the NAAQS.

Annual average NO_2 concentrations were predicted to increase substantially by up to a maximum of 24.3 $\mu g/m^3$ in the immediate vicinity of the site, with the total concentration, including background levels, potentially reaching 96.3 $\mu g/m^3$. As described above, the maximum NO_2 concentrations are conservatively high since they assume a NO to NO_2 conversion rate which is higher than that which would occur at the nearest receptors where the highest values were predicted. Although exceedance of the NO_2 standard is not predicted, mitigation proposed to reduce PM (e.g. electrification) may also reduce NO_2 emissions.

Mesoscale Emissions Analysis

The total predicted emission of PM_{10}, $PM_{2.5}$, NO_2 and VOCs by year due to the proposed construction activity with implementation of the EPCs, including both on–site activity and

related on–road emissions, are presented in Table 15-8. Of the total construction period emissions, approximately 50 to 60 percent of VOC, 70 to 85 percent of NO_2, 60 to 70 percent of PM_{10} and 80 to 90 percent of $PM_{2.5}$ would be from on–site sources.

Table 15–8
Total Mesoscale Direct and Indirect Emissions from Cumulative Construction of the Lower Manhattan Recovery Projects in the Critical Analysis Year

Pollutant	2005	2006	2007	2008
PM_{10}	8.3	9.9	2.7	2.3
$PM_{2.5}$	5.3	5.5	1.4	1.1
NO_2	267.2	287.5	70.4	58.2
VOC	19.3	19.2	6.2	4.9

Notes:
The above results were estimated using the construction analysis framework developed for the Permanent WTC PATH Terminal DEIS. This analysis framework considered 2006 as the peak cumulative construction year for the Lower Manhattan Recovery Projects.

The results presented in Table 15-8 for the PM_{10} emissions include both engine emissions and resuspended road dust. The results also reflect only the Short Bypass Alternative for Route 9A. The South Ferry Terminal construction emissions are estimate based on the worst-case emissions published in the Environmental Assessment, which were based on the assumption that all of the most intense construction activities will take place within one 12-month period in 2005–2006. However, these emissions would not actually occur during one calendar year, and would not persist at the same level over both years as presented here. Therefore, emissions presented in Table 15-8 are a conservative annual estimate for the peak construction year.

As compared to the projected regional emissions inventory in the New York ozone SIP for the same years—the on-road portion of the emissions is estimated at less than 0.06 percent and 0.02 percent of the SIP mobile source NO_2 and VOC emissions, respectively; the on-site portion of the emissions would be 0.4 percent and 0.03 percent of the non-road SIP NO_2 and VOC emissions or less (depending on the year), respectively.

MITIGATION

The EPCs and LMDC's enhanced mitigation commitments were incorporated into the baseline analysis of construction period air quality described above. As described, Chapter 9, "Air Quality," PANYNJ would also commit to additional mitigation measures to reduce the potential construction-period impacts of the Preferred Alternative. Similarly, since publication of the Permanent WTC PATH Terminal DEIS, MTA/NYCT, and NYSDOT have committed to a higher level of mitigation than originally contemplated with the EPCs. The following describes these commitments.

- Electrification: Certain construction engines that operate in a fixed or temporarily fixed position, such as welding machines and compressors, could potentially be connected to the City's power grid if available by Con Edison at the start of construction. The electrification of this equipment would eliminate the on–site diesel exhaust from these sources. However, in some cases, electrification may not prove effective due to the need for mobility, and some local power generation may be needed when access to connection points is not feasible. PANYNJ and MTA/NYCT would require all contractors and subcontractors to use

electrically powered equipment wherever technically feasible, for air compressors, pumps, mixing, desanding and grout plants, welding machines, and any other diesel powered equipment that can be replaced with an electrically powered version. However, this does not apply to PATH's pedestrian concourse beneath Route 9A since NYSDOT has not yet finalized what level of electrification would be possible for its projects.

- Diesel Particle Filters: Technologies are available that can achieve greater reductions in particulate matter emissions as compared to DOCs. DPFs, for example, can reduce particulate matter emission by at least 85 percent and as high as 98 percent. However, DPFs are not effective for every type of engine operation, and there may be technical difficulties in applying DPFs to some engines. The Lower Manhattan project sponsors would require the use of DPFs or other measures with equivalent PM removal efficiency for all nonroad diesel engines of 50 horsepower or greater wherever the implementation of such a device is available and practical. It is assumed that DPFs can be practically used on 75 percent of nonroad diesel engines and that the remaining 25 percent could employ DOCs.

- Newer Engines: The use of new construction engines would ensure that older, higher emitters are not operating on–site and would make the operation of added control technologies easier and more efficient. The Lower Manhattan project sponsors would require the use of post-1995 fuel injection engines, which meet the Tier II engine emissions standards, as defined in Title 40, Part 89.112. Exceptions will be made only for specific engines that are not yet available as Tier II, where the task cannot be reasonably accomplished using alternative engines or means comply with these demands. However, given current technology, it is assumed that all engines would be Tier II compliant.

- The Lower Manhattan project sponsors are investigating the use of other methods to reduce NO_2 emissions. However, given the current uncertainty, additional NO_2 reduction techniques were not assumed as part of the cumulative mitigation analysis.

To model the effectiveness of these enhanced mitigation measures, it was assumed that all engines used for construction of the Fulton Street Transit Center, Route 9A, and the Permanent WTC PATH Terminal construction would be Tier II compliant. Furthermore, it was also assumed that by the critical analysis year, half of all air compressors, pumps, mixing, desanding and grout plants, and welding machines used to construct the Permanent WTC PATH Terminal, excluding the pedestrian concourse beneath Route 9A, would be electrically operated.

Table 15-9 and Figures 15-13 through 15-23 show the predicted increase in pollutant concentrations at Lower Manhattan receptors accounting for the enhanced mitigation measures described above. Total concentrations, including background levels, are presented in Table 15-10. The concentrations at locations adjacent to the construction sites include contributions from both on-road sources and on-site construction activity. The concentrations marked "Other locations Along Access Routes" represent the highest predicted impacts from on-road sources at more distant locations that would not be impacted by the construction activity on-site.

The maximum predicted $PM_{2.5}$ increments with enhanced mitigaiton are significantly lower than those predicted without the further commitments of PANYNJ, MTA/NYCT, and NYSDOT.

Table 15–9
Highest Predicted Increase in Pollutant Concentrations from Cumulative Construction of the Lower Manhattan Recovery Projects with Mitigation in the Critical Analysis Year

Pollutant	Average Period	Receptor Type	Maximum Increase [µg/m³]	
			With Route 9A Short Bypass	With Route 9A At Grade
NO_2	Annual	Highest of All Receptors	24.1**	21.3**
		Residential Buildings / Hotel	21.9**	21.3**
$PM_{2.5}$	24–hour	Highest of All Receptors	24.7*	28.2*
		Residential Buildings / Hotel	5.8*	5.7*
		Other Locations on Access Routes	0.4	0.4
	Annual	Local Highest of All Receptors	1.2*	1.1*
		Local Highest Residential / Hotel	1.0*	1.0*
		Local on Access Routes	0.17	0.17
		Neighborhood Scale	0.24*	0.25*
PM_{10}	24–hour	Highest of All Receptors	41.3	58.8
		Residential Buildings / Hotel	10.9	26.5
		Other Locations on Access Routes	4.5	4.5
	Annual	Highest of All Receptors	3.1	2.7
		Residential Buildings / Hotel	2.2	2.2
		Other Locations on Access Routes	1.4	1.4

Notes:
Interim guidance threshold levels for $PM_{2.5}$ are 5 µg/m³ and 0.3 µg/m³ for 24–hour and annual increases respectively, and 0.1 µg/m³ for neighborhood scale annual average. For determination of adverse impacts, these values are applied in the absence of specific criteria.

* Exceeds the interim guidance thresholds.

** Substantial adverse impact due to high increment predicted where existing background concentrations are high—not exceeding NAAQS (see table 15–10).

With mitigation, the maximum cumulative $PM_{2.5}$ increments would be reduced by approximately 66 percent. More importantly, the exceedance of the PM_{10} 24–hour NAAQS would be eliminated.

As shown in Figures 15-20 and 15–21, the extent of increments above local threshold levels would be significantly reduced, and the potential for exceedance of the $PM_{2.5}$ 24–hour NAAQS would be limited to a single location along the Route 9A bikeway. However, the occurrence of such high levels would depend on the coincidence of peak background levels above the 98th percentile together with peak construction activity and the extreme meteorological conditions that led to the concentration predicted in the model. Such an occurrence, although possible, would be rare. Furthermore, it would be a temporary situation, limited to a small area immediately adjacent to the Route 9A construction site and would not be expected to occur in subsequent years when construction activity would be reduced.

Table 15–10
Highest Predicted Total Pollutant Concentrations
from Cumulative Construction of the Lower Manhattan Recovery Projects with Mitigation in the Critical Analysis Year

Pollutant	Average Period	Receptor Type	Maximum Increase [µg/m³]	
			With Route 9A Short Bypass	With Route 9A At Grade
NO_2	Annual	Highest of All Receptors	96.1	93.3
		Residential Buildings / Hotel	93.9	93.3
$PM_{2.5}$	24–hour	Highest of All Receptors	71.7*	75.2*
		Residential Buildings / Hotel	52.8	52.9
		Other Locations on Access Routes	47.3	47.3
	Annual	Highest of All Receptors	19.3**	19.3**
		Highest Residential / Hotel	19.2**	19.2**
PM_{10}	24–hour	Highest of All Receptors	101.7	119.2
		Residential Buildings / Hotel	70.5	86.4
		Other Locations on Access Routes	63.6	63.6
	Annual	Highest of All Receptors	30.6	30.2
		Residential Buildings / Hotel	28.8	28.6
		Other Locations on Access Routes	28.8	28.8

Notes:

All total concentrations include calculated background contributions from local mobile sources, as well as measured regional background values as follows: NO_2—Annual average 72 µg/m³; $PM_{2.5}$—Annual average 17.1 µg/m³ (highest of 2000-2002 annual values); 24-hour average 44.0 µg/m³ (highest of the three 2nd highest 24-hour averages in 2000-2002); PM_{10}—Annual average 24 µg/m³; 24–hour average 50 µg/m³.

The NAAQS are as follows: NO_2—Annual = 100 µg/m³; $PM_{2.5}$—24–hour = 65 µg/m³ and Annual = 15 µg/m³; PM_{10}—24–hour = 150 µg/m³ and Annual = 50 µg/m³.

Cumulative and project–generated maximum concentrations may occur at a different time and/or location.

* Indicates predicted exceedance of new NAAQS for which the conformity process is not yet in effect.

** $PM_{2.5}$ annual average concentrations exceed the NAAQS in the existing background condition. See Table 15–9 for comparison with incremental thresholds.

Without enhanced mitigation measures, the predicted cumulative increase in NO_2 would not exceed the NAAQS. However, the use of electrification would reduce mesoscale NO_2 emissions substantially. Should this strategy be applied to the Route 9A Project, additional reductions in maximum NO_2 concentrations would be expected.

CONDITIONS WITH THE REVISED SCHEDULES

As described above, maximum $PM_{2.5}$ concentrations, including background and emissions from all construction projects, would increase significantly during construction, and in rare circumstances would exceed the 24-hour standard. NO_2 concentrations were also predicted to increase significantly but would not exceed the NAAQS. These results were predicted both with and without the additional mitigation measures.

Under the revised construction schedules, overall annual NO_x emissions would be lower. PM emissions from the construction of the WTC Memorial and Redevelopment Plan may be 8 percent higher than projected above; however, cumulative short-term PM concentrations should be somewhat lower since peak construction for the Fulton Street Transit Center would not overlap with peak construction for the WTC Memorial and Redevelopment Plan, Permanent WTC PATH Terminal, and Route 9A.

Annual PM emissions from the WTC Memorial and Redevelopment Plan would also be somewhat higher in the peak construction year. However, much of those emissions would be from equipment used to construct the towers, and the vertical dispersion of these emissions throughout the towers would result in lower ground-level results than if construction were concentrated at-grade. When considered cumulatively, the net result would likely be maximum annual $PM_{2.5}$ concentrations similar to those predicted above.

Therefore, the mitigation measures presented above would still be needed to ensure that potential exceedances are limited to the smallest area and shortest duration possible.

NOISE AND VIBRATION

PROBABLE IMPACTS

As discussed in Chapter 10, "Noise and Vibration," construction of the Preferred Alternative would result in adverse noise impacts at sensitive land uses in close proximity to the construction site. These results were based on an analysis of the expected construction activities and duration for the year 2006. The combination of noise from all pieces of equipment operating during the same time period was obtained from adding the L_{eq} values for each piece of equipment. Similarly, a cumulative noise analysis for the Lower Manhattan Recovery Projects has been conducted for a series of receptor locations, which are shown in Figure 15-24. (See Appendix D for information on the on-site and mobile sources assumed in the analysis.)

Table 15-11 shows maximum predicted 8-hour L_{eq} and 30-day L_{dn}/L_{eq} noise levels resulting from construction of the Lower Manhattan Recovery Projects, without mitigation. The predicted construction noise levels generated by the Preferred Alternative, without mitigation, are also shown for comparison. The predicted cumulative levels would exceed the recommended 8-hour L_{eq} and 30-day L_{dn}/L_{eq} thresholds at Sites 1, 2 and 3 but would not exceed the thresholds at Sites 4 and 5.

Table 15-12 shows the cumulative analysis at receptors further from the Project Site. The results at PS 89 indicate that construction traffic along Route 9A in conjunction with equipment several blocks away would not adversely affect ambient noise levels. Similarly, the results at the Embassy Suites and Gateway Plaza indicate that levels one block from the WTC site, west of Route 9A, would also not be adversely affected. The results do indicate that cumulative construction noise levels would exceed impact thresholds at 4 Albany Street and St. Peter's Church. However, the Permanent WTC PATH Terminal's construction would not be a major generator of these noise levels.

The cumulative analysis shows that construction operations would have adverse noise impacts at sensitive receptors adjacent to the various construction sites. In addition, these impacts would occur for a considerable period of time. Similarly, these projects would result in varying degrees of ground vibration, depending on the stage of construction, the equipment and construction

Table 15-11

2006 Cumulative Construction Noise Impacts at Permanent WTC PATH Terminal Receptors (in dBA)

Receptor Site	Location	Land Use Category	FTA Impact Criteria		Cumulative Noise Levels		PATH-Generated Noise Levels		Cumulative Impact	
			8-hour L_{eq}	30-Day *L_{dn}/ L_{eq}	8-hour L_{eq}	30-Day *L_{dn}/ L_{eq}	8-hour L_{eq}	30-Day *L_{dn}/ L_{eq}	8-hour L_{eq}	30-Day *L_{dn}/ L_{eq}
1	Hilton Millennium Hotel	Residential	80	84	95	93	80	74	Yes	Yes
2	114 Liberty Street	Residential	80	81	88	82	80	74	Yes	Yes
3	World Financial Center/Dow Jones, on West Street	Commercial	85	80	88	82	88	81	Yes	Yes
4	Barclay Street and Washington Street Intersection	Commercial	85	80	71	67	69	62	No	No
5	180 Broadway	Residential	80	89	79	77	66	60	No	No

Notes: The 30-day L_{eq} is for commercial uses and the 30-day L_{dn} is for residential uses. At sites 1, 2, and 5 with high ambient noise levels (L_{dn} > 65 dB), the recommended residential uses 30-day L_{dn} thresholds would be existing ambient + 10 dB (e.g. 74 dBA + 10 dBA = 84 dBA at Site 1).

Table 15-12

2006 Cumulative Noise Impacts at Other Nearby Receptors (in dBA)

Site	Location	Land Use Category	FTA Impact Criteria		Cumulative-Generated Noise Levels		Impact	
			8-hour L_{eq}	30-Day *L_{dn}/ L_{eq}	8-hour L_{eq}	30-Day *L_{dn}/ L_{eq}	8-hour L_{eq}	30-Day *L_{dn}/ L_{eq}
6	PS89 Playground	Public Facility	80	87	66	62	No	No
7	Embassy Suites	Hotel	80	81	75	71	No	No
8	Gateway Plaza	Residential	80	77	69	65	No	No
9	4 Albany Street	Residential	80	79	92	87	Yes	Yes
10	95 Trinity	Institutional	80	88	72	66	No	No
11	St Peter's	Church	80	85	81	76	Yes	No
12	West Broadway/Park Place	Residential	80	83	68	63	No	No

Notes: L_{eq} for commercial uses and L_{dn} for residential uses. Results are cumulative without mitigation measures.

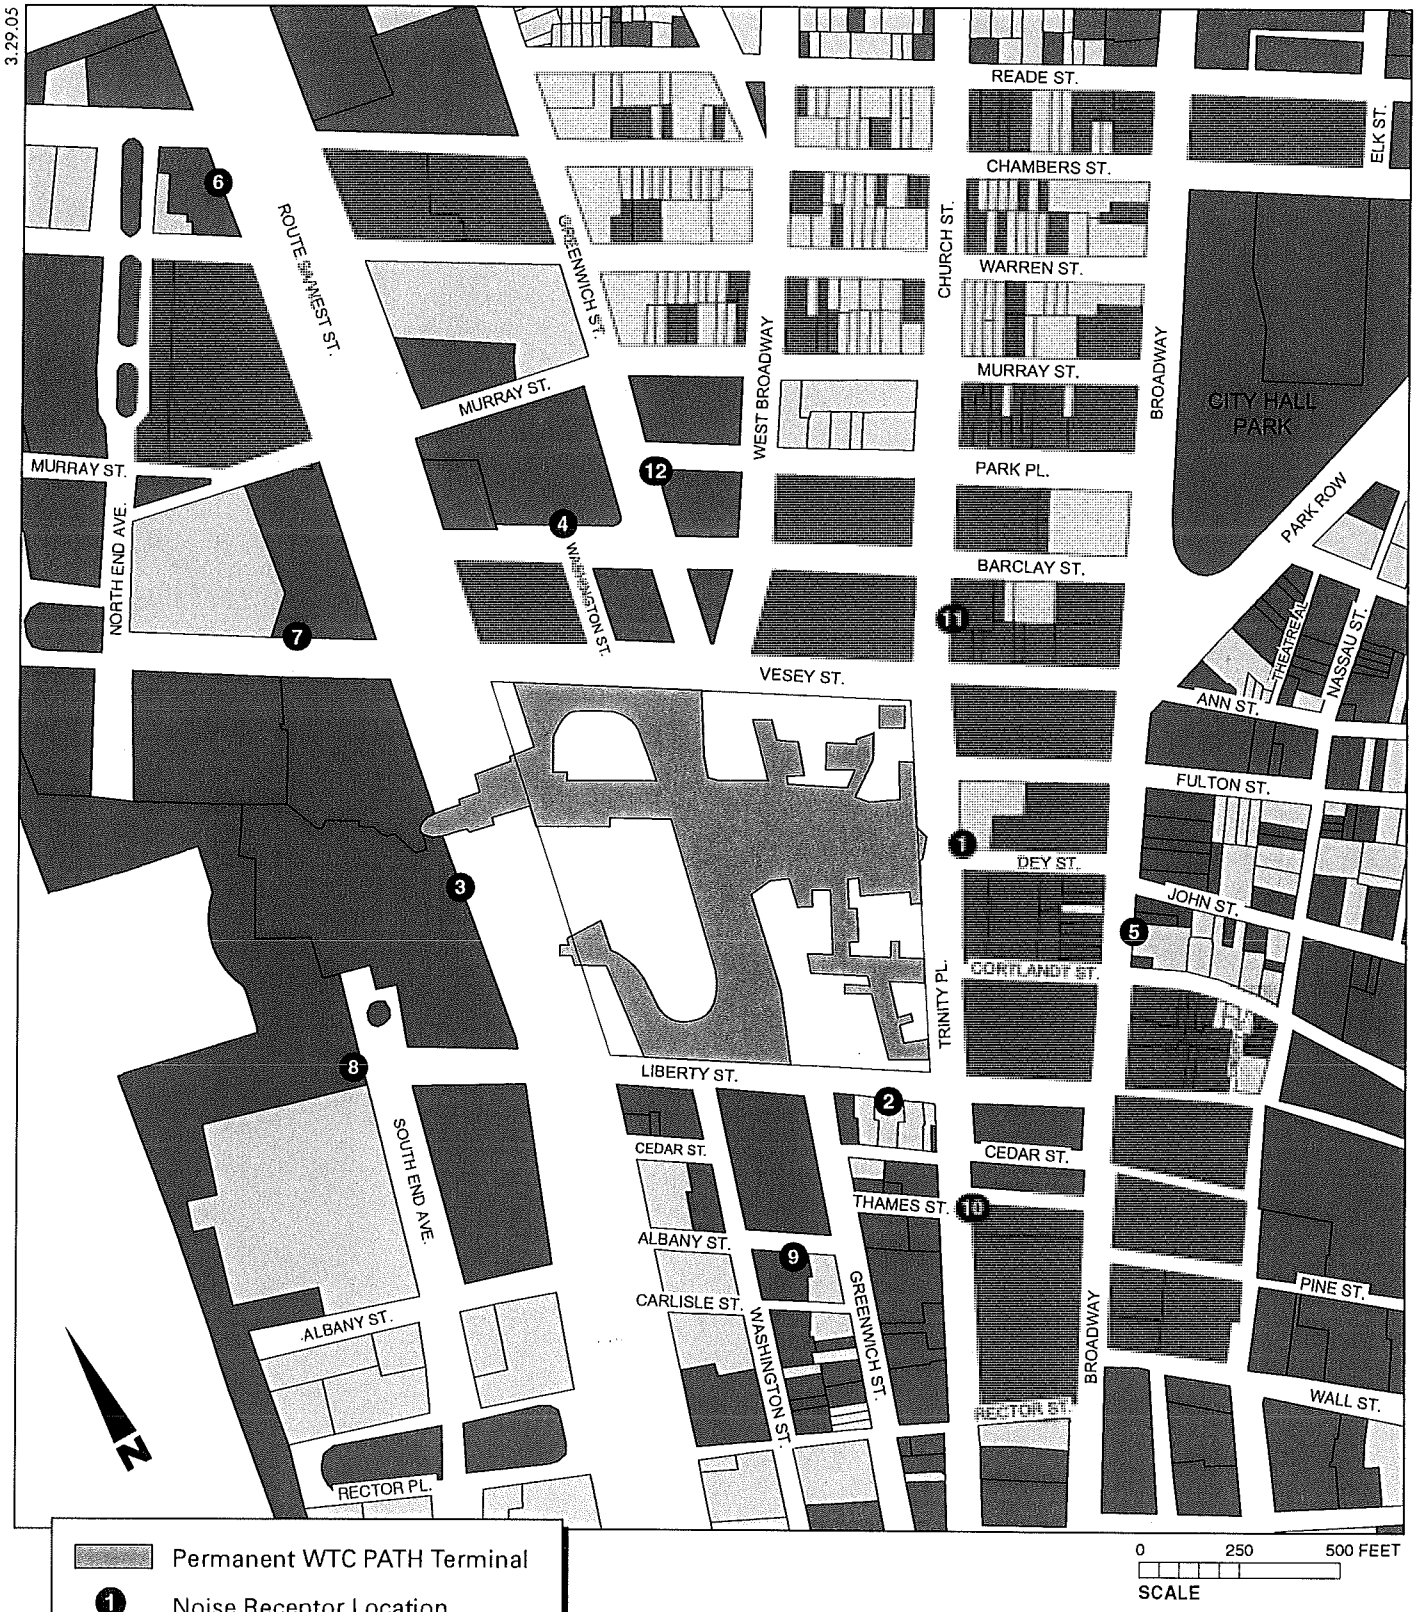

Figure 15-24

Cumulative Noise Receptor Locations and FTA Land Use Categories

methods employed, and the distance from the construction to buildings and vibration sensitive structures. Construction equipment such as pile drivers can produce levels that exceed the 0.12 and 0.20 inches per second vibration damage threshold criterion for fragile buildings at distances of 50 feet. At distances closer to the construction equipment (20 feet or less), additional equipment such as clam shovel drop, caisson drilling, and large bulldozers can produce levels exceeding the vibration threshold criterion for fragile and some extremely fragile buildings.

Figure 15-25 shows the historic/fragile buildings within a 90 foot radius from the Project Site, which captures any potential vibration problems from construction activity.

MITIGATION

As described in Chapter 10, "Noise and Vibration," the implementation of the mitigation measures listed in Table 10-15 would eliminate all construction noise impacts generated by the Preferred Alternative. As described in the executed MOA for the Permanent WTC PATH Terminal, PANYNJ, in consultation with the State Historic Preservation Officer (SHPO) and in coordination with other Lower Manhattan project sponsors, as appropriate, would develop a Construction Protection Plan (CPP) based on the requirements laid out in the "New York City Department of Buildings Technical Policy and Procedure Notice #10/88."

PANYNJ and the other Lower Manhattan project sponsors are also developing construction noise and vibration mitigation measures, examples of which are provided below. Implementation of these mitigation measures is expected to minimize or eliminate construction-related individual and cumulative noise and vibration impacts. The sponsors of the Lower Manhattan Recovery Projects—LMDC, MTA/NYCT, NYSDOT and PANYNJ—are coordinating their efforts through the Lower Manhattan Construction Coordination Group.

- The use of acoustic barriers and walled enclosures around certain construction activities. For example, noise tents/enclosures could be used around workers using jackhammers. A temporary noise barrier of 20-foot in height could be installed along the fence line/property line of the construction zone to reduce the noise levels. In addition, temporary barriers (e.g., wood panels on top of Jersey barriers) could also be positioned adjacent to and moved along slurry walls and other construction operations, etc.;
- The placement of construction equipment in shielded locations, such as below grade in the Project Site;
- The installation of silencers on jackhammers, air compressors, generators, light plants, and cranes to reduce noise levels at specific locations (i.e., adjacent to existing residential);
- The use of electrically operated equipment, rather than combustion equipment;
- The use of soil beds, timber planking and/or exterior rubber lining on truck body and aluminum carrying case to reduce rock impact noise during truck load/unloading operations;
- The use of drive-through street-level truck enclosures for truck loading and unloading;
- The use of sheds/enclosures at concrete pump sites during concrete truck unloading; and
- The placement of most loading/unloading inside the bathtub and away from areas at street level.
- The designation of central areas within projects for noisy activities, such as cutting steel or wood or use of noisy equipment such as impact wrenches. Use of pre-cut, pre-fabricated, or

modular construction materials that minimize need for on-site fabrication or cutting methods.

Measures to monitor construction noise levels would be undertaken throughout the construction period. These programmatic measures would be administered through either the Command Center and/or the Lower Manhattan Construction Coordination Group. These actions may include:

- Enforcement of designated truck routes during construction;
- Adherence to construction equipment noise performance standards specified by EPA and possible development of additional standards by the Lower Manhattan Construction Coordination Group;
- Noise monitoring before construction begins, to establish baseline noise levels, and ongoing monitoring during the various construction phases; and
- Evaluation of the noise reduction potential, and cost effectiveness, of alternative construction methods and/or changes to the sequencing of construction activities.

CONDITIONS WITH THE REVISED SCHEDULES

The analysis presented above showed 5 receptor sites that would experience significant adverse 8-hour L_{eq} noise impacts in the peak construction year without mitigation. Under the schedule refinements (see page 15-8), two of these sites, 4 Albany Street and 114 Liberty Street, would experience higher 8-hour L_{eq} noise levels than predicted above. However, there would be a slight decrease or no change in predicted levels for the World Financial Center, the Millennium Hotel, and St. Peter's Church; however, these sites would continue to exceed the FTA impact criteria.

The 30-day L_{dn}/L_{eq} noise levels would be higher with the schedule refinements at the 4 Albany Street, 114 Liberty Street, and 95 Trinity Street receptors as compared to the analysis presented above. These increases likely result from activities on the Deutsche Bank site that would occur in the peak year. Although the schedule refinements would result in some modest increases in noise levels, there would be no change in the number or location of 30-day, cumulative noise impacts in the peak construction year.

CULTURAL AND HISTORIC RESOURCES

PROBABLE IMPACTS

The EPCs specify that individual project sponsors consider the cumulative construction-period impacts to cultural resources within their respective Areas of Potential Effect (APEs). As described in Chapter 6, "Cultural Resources," the Permanent WTC PATH Terminal's APE contains 21 resources that are listed or are eligible for listing on the State or National Register of Historic Places. The assessments presented in Chapter 6 identified seven resources within the APE that may be impacted by the facility's construction. These resources are shown in Table 15-13 along with the potential impacts from the other Lower Manhattan Recovery Projects.

MITIGATION

Pursuant to the executed MOA for the Permanent WTC PATH Terminal, PANYNJ would prepare Construction Protection Plans (CPPs) for historic structures that may be impacted by construction period vibrations (see Appendix B). As stipulated in the MOA, these plans would

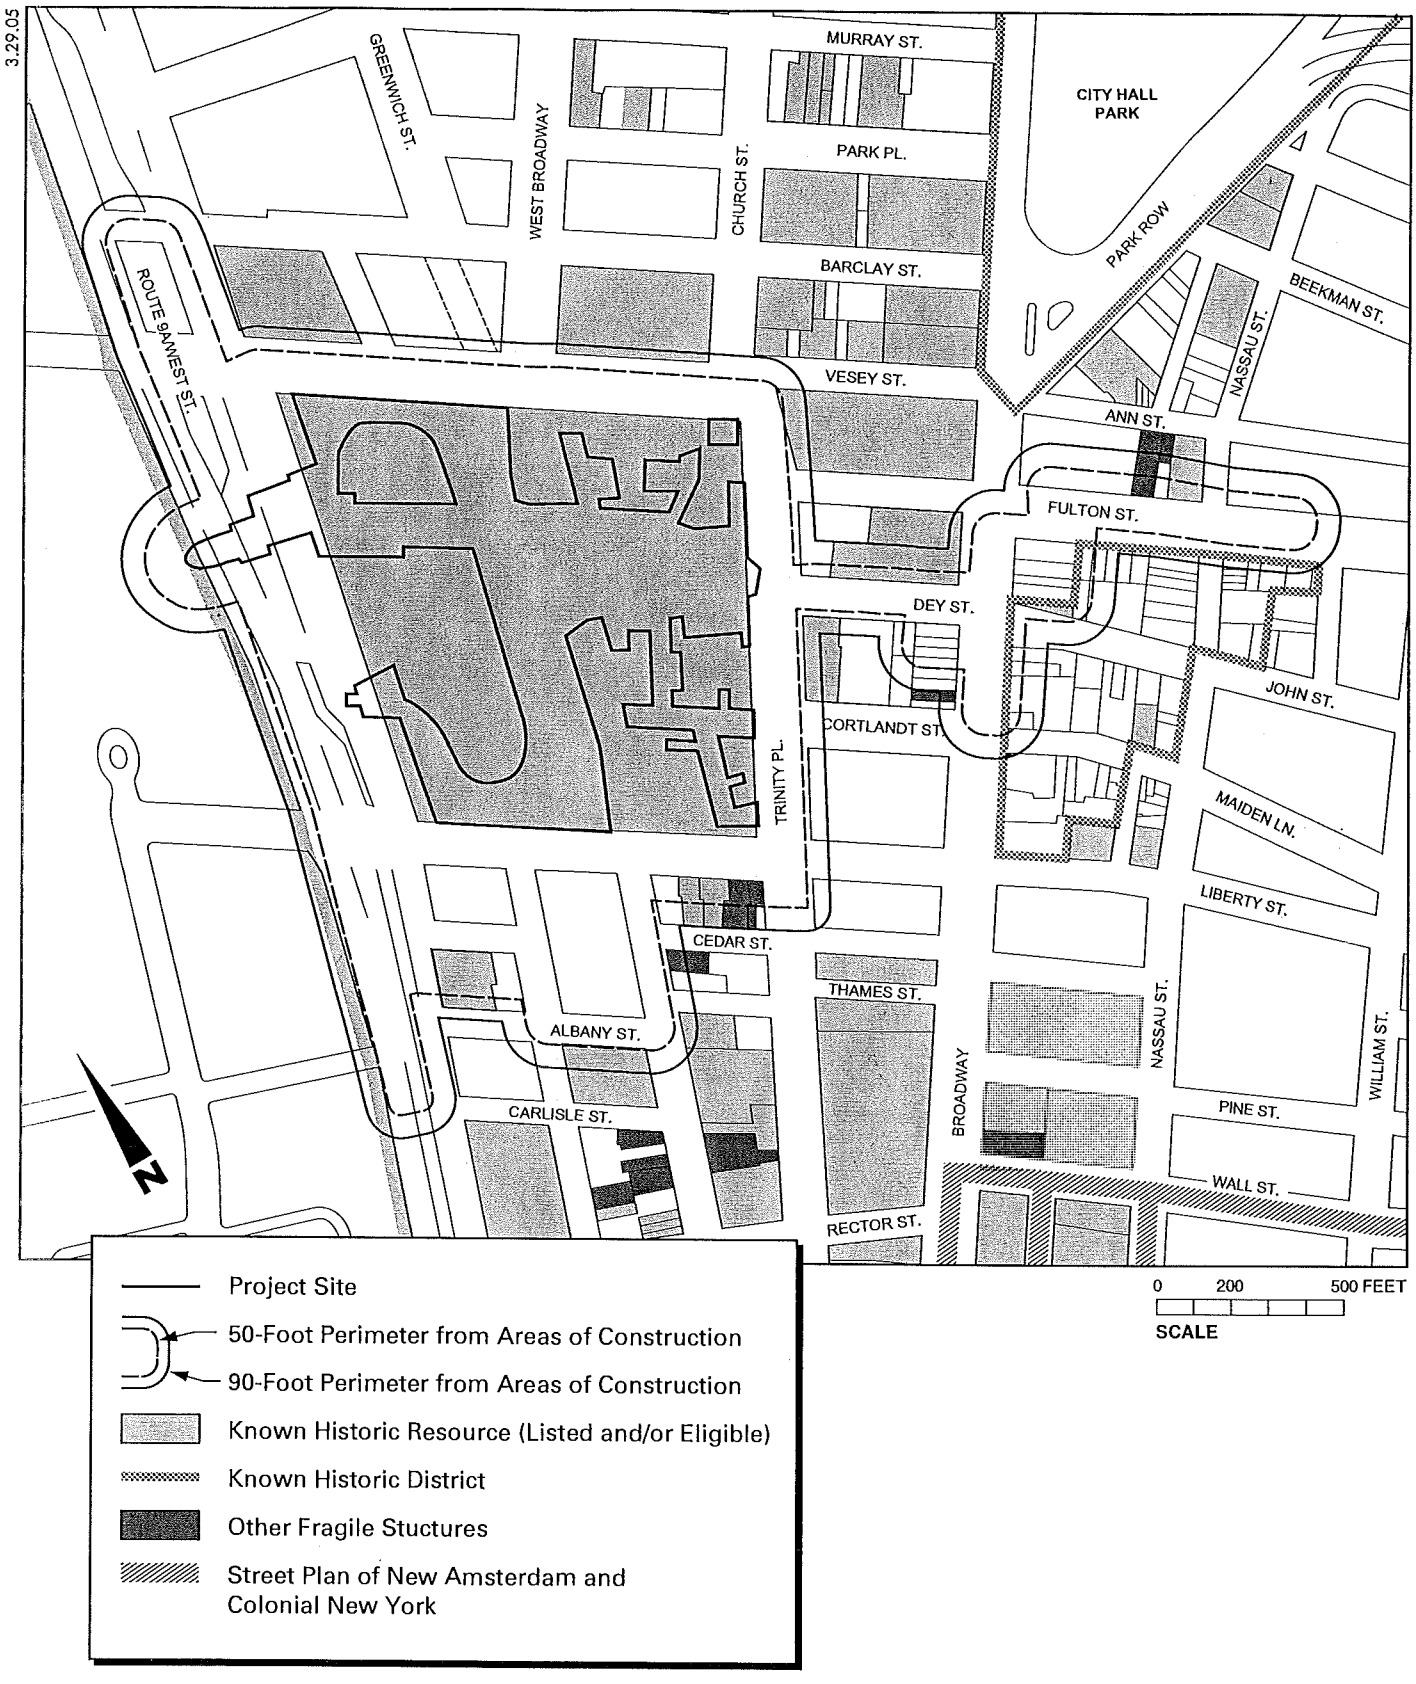

Figure 15-25

Known or Potential Historic Structures and Potential Vibration Areas from Cumulative Construction Activities

Table 15-13
Cumulative Effects to Known Historic Resources within the Area of Potential Effect for the Permanent WTC PATH Terminal

Resource	Project	Potential Impact
Hudson River Bulkhead Battery to West 59th St.	PATH	Potential disturbance during construction of the Route 9A pedestrian concourse

WTC Site	PATH	The Terminal's construction has an adverse effect on the WTC site; Potential archaeological sites in the eastern portion of the WTC site may be disturbed.
	Route 9A	The project has the potential to impact the site's west bathtub wall.
	LMDC	Potential archaeological sites in the eastern portion of the WTC site may be disturbed. The project has the potential to affect other remaining remnants and structures on the site.
	FSTC	The project would abut the Church Street frontage of the site.

Notes: PATH = Permanent WTC PATH Terminal (PANYNJ)
LMDC = World Trade Center Memorial and Redevelopment Plan (LMDC)
Route 9A = Route 9A Project (NYSDOT)
FSTC = Fulton Street Transit Center (MTA/NYCT)

be coordinated with NYSDOT, LMDC, and/or MTA/NYCT, as appropriate, for sites that may be cumulatively affected by construction. The CPPs would avoid or minimize the potential cumulative effects on seven of the nine historic properties identified in Table 15-13.

The Hudson River Bulkhead may be cumulatively affected by the construction of PATH's east-west concourse and by construction of Route 9A. As described in the executed MOA for the Permanent WTC PATH Terminal, PANYNJ would develop and implement a plan to locate and identify intact portions that would be affected by the concourse's construction. This plan would be developed in consultation with SHPO and in coordination with NYSDOT. In the event that intact portions of the Bulkhead are identified within the vicinity of the east-west pedestrian concourse, PANYNJ, in consultation with SHPO and in coordination with NYSDOT, would prepare a treatment plan for these portions of the Bulkhead.

The executed MOA also provides for stipulations to address potential cumulative effects from construction on the WTC site. As described in the MOA, PANYNJ would request that all agencies constructing projects within the WTC site submit preliminary and pre-final design documents to PANYNJ. PANYNJ and its designated historic preservation consultant would consult with SHPO and the Lower Manhattan Emergency Preservation Fund to asses whether there would be potential for a cumulative adverse effect from the Permanent WTC PATH Terminal and other WTC site projects based on the preliminary and pre-final plans. If SHPO and PANYNJ, agree that planned or completed activities would result in cumulative adverse effects on the WTC site, then PANYNJ would consider measures with respect to the Permanent WTC PATH Terminal to mitigate or minimize these effects, including technical or financial measures for the protection, stabilization, or repair of resources and/or modifications to the Preferred

Alternative's design. PANYNJ would make its documentation of potential cumulative effects and accompanying mitigation plans available for review by the National Park Service, the Advisory Council on Historic Preservation, the Lower Manhattan project sponsors, and the Section 106 consulting parties. PANYNJ's plans to minimize or mitigate adverse cumulative effects would also consider the stipulations within the Programmatic Agreements for the WTC Memorial and Redevelopment Plan, the Route 9A Project, and the Fulton Street Transit Center.

CONDITIONS WITH THE REVISED SCHEDULES

The refinements to the construction schedules would not alter the APEs for the Lower Manhattan Recovery Project or their potential impacts to the historic and archaeological resources identified in Table 15-13. Therefore, the cumulative effects findings presented above would not change with the schedule refinements.

ECONOMIC CONDITIONS

PROBABLE IMPACTS

The five Lower Manhattan Recovery Projects would create thousands of jobs during the construction period. Not only would these projects spur employment within Lower Manhattan, but they would provide jobs for the region, as a whole, with the off-site production of materials. These projects would also directly enhance the local economy with the expenditure of dollars for labor and materials and with the generation of tax revenues.

In addition to the effects on the local economy, businesses in Lower Manhattan would benefit from daily expenditures by the construction workforce induced by the recovery projects. This would provide an expanded customer base for retail and convenience stores, restaurants, delicatessens, and pharmacies.

Construction activities in general have the potential to disrupt business and retail operations as a result of restricted access for pedestrians (customers) and vehicles (deliveries). Construction of the Preferred Alternative itself is unlikely to directly restrict access for extended periods of time during its construction stage since most activities would be contained within the WTC site. Some access restrictions may occur on streets surrounding the WTC site with construction of the Route 9A pedestrian connection, but PANYNJ would work with NYSDOT and the NYCDOT to implement a Maintenance and Protection of Traffic (MPT) Plan to maintain movement through these areas to the extent possible (see Chapter 8, Section B, "Vehicular Traffic and Parking.")

Construction of the WTC Memorial and Redevelopment Plan is not expected to result in the long-term, full-closure of streets in Lower Manhattan because most construction activities would be within the WTC site itself. For activities that may require disruption to traffic, LMDC would develop a MPT Plan in coordination with the other project sponsors to ensure that access to local businesses is maintained throughout the construction period.

The Fulton Street Transit Center would include construction of the Dey Street Passageway between Broadway and Church Street and the pedestrian connector between the Cortlandt Street (R and W) subway station at Church Street and the E subway terminal on the WTC site. The construction at Dey Street would affect deliveries to Dey Street and in particular Century 21, a major department store in the area. Access to Century 21 could also be affected by construction truck traffic associated with the Preferred Alternative as well as the Fulton Street Transit Center,

the WTC Memorial and Redevelopment Plan, and NYCDDC's proposed reconstruction of Church Street.

Vehicular access to portions of Fulton Street would also be temporarily disrupted in certain locations; however, alternate access points would be made available for service and deliveries. For example, alternative loading areas could be established on the north side of Cortlandt Street during construction to enable truck access to Century 21.

As currently planned, NYSDOT would maintain four lanes of traffic through their construction zone during most periods of the day. In addition, NYSDOT has completed a pedestrian bridge across Route 9A at Vesey Street that would connect to an at-grade, protected pedestrian walkway along Vesey Street. Together these temporary measures would maintain access between Church Street and Battery Park City for businesses, workers, commuters, and residents.

MITIGATION

Chapter 5, "Socioeconomic Conditions," shows the EPCs and proposed implementation plans that pertain to business access and economic conditions. As per the guidance of the EPCs, the sponsors of the Lower Manhattan Recovery Projects are working with NYSDOT and NYCDOT to develop a Construction Management Plan (CMP) for Lower Manhattan that would coordinate the MPT plans of the individual projects. The CMP would ensure access is maintained through the area as individual projects proceed into their construction phases. This coordinated plan would help to minimize the potential adverse economic effects to business during the construction period.

The sponsors of the Lower Manhattan Recovery Projects would also provide for temporary signage to direct vehicles and pedestrians to businesses within the construction zone. These efforts would be coordinated between the sponsors and with the effected businesses to ensure that the maximum visibility for these businesses would be achieved.

CONDITIONS WITH THE REVISED SCHEDULES

The schedule refinements would delay construction of three of the five Recovery Projects, which could result in fewer cumulative effects in the peak construction year. However, these refinements would not alter the limits of the project site nor the necessary construction staging areas. As such, the effects to local businesses presented above would not change substantially with the schedule refinements.

D. PROBABLE OPENING YEAR (2009) AND DESIGN YEAR (2025) EFFECTS

The federal government has committed billions of dollars for the redevelopment and revitalization of Lower Manhattan. These funds recognize the devastating short- and long-term effects of the terrorist attacks to Lower Manhattan and the region, as a whole. As such, the five major Lower Manhattan Recovery Projects have been planned and coordinated to provide for the short-term recovery of facilities that were damaged or lost and the long-term economic vitality of Lower Manhattan, New York City, and the region as a whole.

Within the framework of each individual project's environmental review processes, alternatives are being evaluated for their potential direct and indirect environmental impacts. When considered cumulatively, some of these alternatives may limit the long-term benefits of the

Lower Manhattan recovery efforts. The assessment of short-term, construction-period impacts considered the cumulative effect of the Preferred Alternative, with the other Lower Manhattan Recovery Projects since this alternative would generate a greater number of impacts during the construction period than would the No Action Alternatives. Thus the above analysis is the most conservative of the alternatives for the Permanent WTC PATH Terminal. In the long-term, however, each of the alternatives for a Permanent WTC PATH Terminal has the potential for considerably different effects in the opening year (2009) and design year (2025). Thus, the long-term, operational effects discussion below provides a description of the potential benefits and limitations of both the No Action and Preferred Alternatives for the cumulative effects on the resource areas defined above.

NO ACTION ALTERNATIVE

In the long-term, the No Action Alternative would result in the full disruption of PATH service to Lower Manhattan at some point between 2009 and 2025. As such, the cumulative effect of the No Action Alternative on and with the other Lower Manhattan Recovery Projects would be detrimental.

The No Action Alternative could generate up to 1,200 new vehicle trips into Manhattan in the AM peak hour by 2025. These new vehicle trips would congest area roadways and would limit access to businesses for customers and deliveries. The No Action Alternative would also increase on-street pedestrian congestion since it would not provide for sub-grade concourses through the WTC site. Thus, there would be substantial crowding of crosswalks and sidewalks on and near the WTC site, resulting in reduced traffic flow. Furthermore, the larger volume of pedestrians that would cross Route 9A would limit the future roadway's ability to process vehicular traffic and may necessitate the construction of a pedestrian bridge.

Because the No Action Alternative would increase vehicular traffic in Lower Manhattan, it would increase emissions and noise levels. The cumulative effect of a No Action Alternative for the Permanent WTC PATH Terminal may degrade air quality and noise levels as compared to pre-September 11, 2001 conditions. Over the long-term, increased traffic congestion, reduced air quality, and higher noise levels would degrade the quality of life for Lower Manhattan's residents and workers.

Increased congestion associated with the No Action Alternative would limit access to, from, and within Lower Manhattan. This would degrade the ability of visitors to access the area's many cultural sites and would reduce the capabilities of local businesses to serve customers and get deliveries. Because the No Action Alternative may limit or fully disrupt direct transit service between Lower Manhattan and New Jersey, it may force residents, commuters, and visitors to use more costly or more time consuming modes of travel. By reducing access to and from Lower Manhattan, the No Action Alternative has the potential to stagnate the overall recovery of Lower Manhattan, including the full redevelopment of the WTC site.

PREFERRED ALTERNATIVE

The Preferred Alternative has been planned and designed in cooperation with the Lower Manhattan Recovery Projects in its vicinity including the Fulton Street Transit Center, Route 9A Project, and the WTC Memorial and Redevelopment Plan. In the long-term, these projects would collectively provide for the integration of land use and transportation in the vicinity of the WTC site and would be an enhancement over pre-September 11, 2001 conditions.

The Preferred Alternative would form a critical sub-grade pedestrian link between BPC, the WTC Site, PATH trains, and the Fulton Street Transit Center's Dey Street Underpass to provide all-weather access between Tran-Hudson Ferries and the World Financial Center and the majority of the subway lines that serve Lower Manhattan. Furthermore, the Route 9A connection would reduce at-grade pedestrian trips during peak commuter periods. As a result, traffic circulation would be improved in the vicinity of the WTC site, which has resultant economic, traffic, air quality, and noise benefits.

The collection of transit services that would be offered by the Preferred Alternative in concert with a new trans-Hudson ferry terminal; a Fulton Street Transit Center; and other potential transportation projects, such as JFK airport access, would strengthen Lower Manhattan's role as a regional transit hub. As such, the area would attract scores of daily commuters and visitors who would frequent local retail establishments such as shops and restaurants. Furthermore, the integration of numerous transit services with the ability to serve residents throughout the region would increase the attractiveness of Lower Manhattan as a center of commerce. ✳

A. INTRODUCTION

In accordance with the National Environmental Policy Act (NEPA) and the Council on Environmental Quality's implementing procedures under 40 CFR Part 1502, any environmental impact statement (EIS) prepared pursuant to NEPA must include an analysis of both the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity, and of any irreversible or irretrievable commitments of resources that would occur should the action be implemented (40 CFR 1502.16). This chapter addresses these concepts for the No Action and the Preferred Alternative. First, the permanent commitment of resources as compared to the benefits of the project is assessed. This analysis is followed by an analysis of the relationship between expending environmental resources in the short-term and gaining productivity in the long-term. This chapter ends with a description of the funding sources for the project and describes how the commitment of these funds may affect other proposals within the New York City region or elsewhere.

B. IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

The No Action Alternative, by definition, would not irreversibly or irretrievably commit resources for construction. However, this alternative would require a greater commitment of a variety of resources in the future due to its failure to improve the accessibility and efficiency of the Region's transportation system.

Resources that may be irreversibly and irretrievably committed to the Preferred Alternative include construction materials, energy, labor, funds, and land. Materials, energy supplies, and labor used to construct the Preferred Alternative are not in short supply, and their use would not have an adverse impact on their continued availability for other projects. Furthermore, construction expenditures are consistent with public policy initiatives to revitalize Lower Manhattan (see Section C, "Cost and Funding").

The total commitment of funds required for construction of the Preferred Alternative, including its pedestrian connections, is estimated at $2,138 billion in 2003 dollars. As described in Chapter 5, "Socioeconomic Conditions," this commitment of financial resources would add to local and regional economic activity and thus add employment and tax revenues in the region.

As shown in Table 16-1 the Preferred Alternative would generate 19,965 person-years of employment during the construction period, which would translate to $1,184.9 million in wages and salaries. The direct expenditures for construction combined with induced expenditures within the region from the employment it would generate would result in $3,970.6 million in expenditures within New York State. Government entities would also benefit from increased tax

Table 16-1
Employment and Fiscal Benefits from Construction of the Preferred Alternative

Employment (in person-years)*	
Direct (Construction)	10,533
Indirect (Secondary and Induced)	9,432
Total	19,965
Wages and Salaries (in millions of dollars)	
Direct (Construction)	$661.5
Indirect (Secondary and Induced)	$523.4
Total	$1,184.9
Total Economic Output or Demand** (in millions of dollars)	
(Millions)	
Direct (Construction)	$2,138.0
Indirect (Secondary and Induced)	$1,832.6
Total	$3,970.6
Tax Revenues***	
New York City Taxes	$46,485.5
MTA Taxes	$2,963.0
New York State Taxes	$96,809.5
Total	$146,258.0

Notes:

* A person-year is the equivalent of one person working full-time for a year.

** The economic output or total effect on the local economy derived from the direct construction spending.

*** Includes personal income taxes, corporate and business taxes, sales tax on indirect expenditures, and numerous other taxes on construction and secondary expenditures. Values are expressed in constant 2003 dollars.

Sources: The characteristics and construction cost of the Project Alternative; the Regional Input-Output Modeling System (RIMS II), U.S. Department of Commerce, Bureau of Economic Analysis; and the tax rates by applicable jurisdiction.

revenues resulting from construction. Under the Preferred Alternative, more than $146 million in tax revenues would be generated by construction-period payroll taxes, sales taxes, and other tax revenue sources.

As described in this EIS, construction of the Preferred Alternative would or potentially would adversely impact historic and archaeological resources, vehicular traffic circulation, access to local businesses, air quality, and noise and vibration.

The Port Authority of New York and New Jersey (PANYNJ) would endeavor to minimize impacts wherever practicable. To that end, it has established and implemented Environmental Performance Commitments (EPCs) and is developing Sustainable/"Green" Design Standards. Furthermore, the Federal Transit Administration (FTA) and PANYNJ have executed a Memorandum of Agreement (MOA) that stipulates measures to avoid, minimize, or mitigate specific impacts to historic resources during the project's construction.

As described in Chapter 2, "Project Alternatives," and Chapter 3, "Construction Methods and Materials," PANYNJ has coordinated with the Lower Manhattan Development Corporation (LMDC), New York State Department of Transportation (NYSDOT), and Metropolitan

Transportation Authority (MTA) to develop EPCs that would avoid or minimize the impacts to the environment during construction of their respective projects. These EPCs specifically address five key environmental concerns: air quality, noise and vibration, cultural and historic resources, access and circulation, and economic effects. Collectively, the EPCs would reduce traffic delays, air quality emissions, noise, and vibration and would minimize effects to the surrounding environment through efforts to maintain access to local businesses, residences, and cultural institutions and resources during the construction period.

The EPCs also established general guidance for the preparation of "green" design and sustainability principals to reduce the demand for and use of resources during construction and once projects are complete. As described in Chapter 2, "Project Alternatives," PANYNJ is developing sustainable design guidelines for the Preferred Alternative. Proposed principals and actions will be organized into six component areas: urban considerations, site, water, energy, materials, and indoor environment. These guidelines are consistent with criteria contained in the New York City Transit Environmental Guidelines, the U.S. Green Building Council's Leadership in Energy Efficiency (LEED) Guidelines 2.1, and requirements of New York State Executive Order 111 and the New York State Green Building Tax Credit. The guidelines would facilitate reuse of or reduced demand for water, energy, and solid waste when the Preferred Alternative is operational. Other measures would promote development that is sensitive to the environment by encouraging users to decrease their demand for nonrenewable resources. PANYNJ's would achieve these guidelines by implementing a number of plans and protocols to minimize demand for and use of resources during and after construction (see Chapter 2, Project Alternatives," and Chapter 11, "Infrastructure and Energy").

In the long-term, the Preferred Alternative would occupy land within and outside the WTC site. The proposed Terminal building and most of its sub-grade concourses would be located within the WTC site, which is owned by PANYNJ. The proposed Route 9A pedestrian connection would extend below Route 9A to a new head house in front of the World Financial Center. The Route 9A connection would occupy land that is not currently controlled by PANYNJ. However, PANYNJ would establish easements and agreements with the property owners prior to construction. The only portion of the Route 9A connection that would be located above-grade would be within the lawn in front of the Winter Garden. Although the new head house would irreversibly commit land to the project, it would provide for substantial benefits to current and future users of Battery Park City and the World Financial Center.

The Permanent WTC PATH Terminal would permanently occupy portions of the approximately 16-acre WTC site. Thus, the Preferred Alternative would irreversibly commit historic land to the project. However, the executed MOA provides for measures to avoid, minimize, or mitigate the project's long-term impacts to the WTC site. As described in Chapter 6, "Cultural Resources," the MOA includes stipulations to preserve certain remnants and structures that remain and to mitigate the project's impacts to other remnants and structures.

The Preferred Alternative would require the irreversible and irretrievable commitment of energy sources both during and after construction.

C. SHORT-TERM USES VERSUS LONG-TERM PRODUCTIVITY

Short-term effects on the environment result from construction impacts. Long-term effects relate to the maintenance and enhancement of long-term productivity—in particular, the consistency of the project with long-term economic, social, and regional and local planning objectives,

including sustainability. The short- and long-term effects of the Preferred Alternative are summarized below.

SHORT-TERM USES

As described elsewhere in this EIS, the Preferred Alternative would have greater "short-term" impacts during construction than the No Action Alternative. Generally, the short-term construction impacts of the Preferred Alternative would be associated with traffic circulation, noise and vibration, air quality emissions, and access to local businesses. PANYNJ would endeavor to reduce these impacts through the EPCs, stipulations of its MOA, and sustainable construction techniques identified in the design guidelines. The Project's construction would create economic benefits in the form of jobs and the subsequent direct and indirect demand for goods and services (see Table 16-1).

LONG-TERM PRODUCTIVITY

The ability of transportation systems to conveniently serve major residential and employment centers is one of the essential components in economic growth and productivity as well as a key factor in improving the livability of neighborhoods; this is particularly true for the New York metropolitan area, and for the economic engine represented by Lower Manhattan.

Before September 11, 2001, nearly 426,000 people worked south of Canal Street, representing 19 percent of Manhattan's total of 1.9 million private sector jobs. However, the terrorist attacks resulted in the loss more than 71,000 jobs south of Canal Street. The renovation and reoccupation of damaged buildings, construction of new buildings, and redevelopment of the WTC site would result in a total of approximately 422,000 jobs south of Canal Street by 2025, which represents a very slight decrease in Lower Manhattan's employment as compared to pre-September 11, 2001 conditions.

The anticipated return of Lower Manhattan's employment is dependent on access to the area from the region's major residential areas. As described in Chapter 1, "Purpose and Need," approximately 16 percent of Lower Manhattan's workforce resided in New Jersey before September 11, 2001, the majority of which traveled by PATH. By improving the transportation infrastructure, the Preferred Alternative would help maintain Lower Manhattan's attractiveness as a global center of finance and commerce. Furthermore, since Lower Manhattan and the City contribute greatly to the economy of the tri-state area, the region would see long-term productivity benefits from the project.

As described in Chapter 8, Section B, "Vehicular Traffic and Parking," the absence of a Permanent WTC PATH Terminal, the No Action Alternative, has the potential to generate new vehicle trips from the diversion of PATH customers to other modes of transit, private automobiles, buses, and commuter vans. By 2025, it is estimated that absent the Preferred Alternative, a total of 1,194 AM peak hour new vehicle trips may be generated. These new vehicle trips would contribute to congestion on local roads as well as at the major portals to Lower Manhattan from New Jersey. Thus, the No Action Alternative may have adverse impacts on regional traffic flow.

Absent the Preferred Alternative, new vehicle trips would contribute to degradation in air quality and noise in Lower Manhattan and the region as a whole. If PATH service between New Jersey and Lower Manhattan is not available in 2025, it is estimated that vehicle trips by diverted PATH customers would emit approximately 15.7 tons per year of volatile organic compounds,

18.0 tons per year of nitrous oxides, 1.5 tons per year or more of particulate matter, and 236.0 tons per year of carbon monoxide in 2025. These new vehicle trips would also increase noise levels near the major portals between New Jersey and Lower Manhattan as well as on the local streets in the vicinity of the WTC site.

As described in Chapter 8, Section A, "PATH" and Chapter 8, Section C, "Transit," the No Action Alternative may result in the overcrowding of the other transit modes that serve or conveniently connect with Lower Manhattan. By 2025, it is estimated that diverted PATH customers could increase ridership on the uptown PATH routes by 4,583, on New York City Tranist subways by 11,611, on New Jersey Transit Commuter rail by 5,500, on buses by 7,495, and on trans-Hudson ferries by 10,694. In order to accommodate this demand, operators would need to provide additional trains, buses, and vessels. Furthermore, the increased crowding of transit vehicles and stations would have adverse impacts to their operation.

The Preferred Alternative would not only avert the adverse impacts of the No Action Alternative but would also provide for improved PATH service as compared to the pre-September 11, 2001 and temporary WTC facilities.

- It would provide for an additional platform to increase capacity and reduce crowding during peak periods.
- It would fully restore the pedestrian connections that existed before September 11, 2001 and provide for new concourses to trans-Hudson ferries, and the Fulton Street Transit Center.
- It would replace the temporary station's 8-car platforms with 10-car platforms, which would allow PANYNJ to operate 10-car trains on the Newark-WTC route.
- It would provide for the operational flexibility to support PATH's long-term service plans.
- Its design would incorporate advanced technologies to enhance security and reduce energy demand.

As described above, the long-term benefits to productivity and related long-term increases in productivity, addressed by the Preferred Alternative, would include the following:

- Support the region's economic development;
- Improved regional and local accessibility;
- Reduced vehicle trips;
- Reduced congestion and overcrowding on other transit systems;
- Reductions in mobile source air pollutants;
- Reductions in traffic generated noise; and
- Improved PATH service.

Overall, the resources to construct and operate the Preferred Alternative would be committed to benefit commuters to and residents of Lower Manhattan. The Preferred Alternative would benefit the New York region by improving access to, from, and within Lower Manhattan. It would offer reductions in station crowding and operational delays as compared to pre-September 11, 2001 conditions. Furthermore, the Preferred Alternative would result in overall reductions in travel time and cost, vehicle trips, and air quality emissions as compared to the No Action Alternative.

SHORT-TERM USES VERSUS LONG-TERM PRODUCTIVITY

Local short-term impacts in use of resources resulting from the construction of the Preferred Alternative would be consistent with the maintenance and enhancement of long-term productivity for the city, state, and region. Some resources that would be valuable in the short term are being spent to achieve higher productivity in the long term. By investing these resources in future productivity, and over the long term, fewer resources would be needed to achieve the same level of productivity than if a No Action Alternative were pursued.

D. COST AND FUNDING

As described in Chapter 2, "Project Alternatives," the estimated cost to construct the Preferred Alternative is $2,138 billion. This cost includes constructing the terminal house; four sub-grade levels; rehabilitation of the tracks and platforms; off-site pedestrian connections; ventilation structures; and the necessary infrastructure work to support the PATH Terminal. The project cost also accounts for the advanced security measures that would be incorporated into the design as well as the sustainable design standards and mitigation of the adverse impacts of the Preferred Alternative.

A total of $1.75 billion would be funded by the Federal Transit Administration as part of the $4.55-billion dollar transportation recovery package, which was committed by the federal government to the City following the terrorist attacks of September 11, 2001. The remaining $388 million would be funded by PANYNJ through their capital improvement program.

The $4.55-billion transportation recovery package was committed to New York City by the federal government to fund transportation projects that support the City's long-term, economic recovery from the terrorist attacks. New York State Governor George Pataki identified four projects for early funding under the transportation recovery package as follows:

- Permanent WTC PATH Terminal;
- Fulton Street Transit Center;
- South Ferry Terminal; and
- The Route 9A Project.

Although Governor Pataki has identified other projects within New York City that may be supported with these funds, the four priority projects are being advanced first.

Because the transportation recovery package is dedicated to New York City, funds must support transportation projects that directly benefit the City. Should any of the four priority projects not advance as planned or if actual costs are lower than currently projected, the additional funds would be used to support the other transportation improvements that have been identified by Governor Pataki.

PANYNJ has planned for contingency costs within the project's budget should construction overruns occur. In the event that the project exceeds the estimated $2,138 budget, PANYNJ, the State of New York, and the federal government would cooperate to ensure that the project is completed. ✳

A. INTRODUCTION

This chapter identifies safety and security considerations related to the design, construction, and operation of the Preferred Alternative. The project would feature advanced safety and security systems and procedures to protect passengers, workers, and the local community. The chapter addresses procedures to be implemented both during the project's construction and once the Terminal is in operation.

B. CONSTRUCTION PERIOD (2006)

The Port Authority of New York and New Jersey (PANYNJ) and the Port Authority Trans-Hudson (PATH) Corporation have extensive experience managing safety and security in both the construction and operation of complex projects. Using this experience, as an initial and key step in the development of the construction plan for the Preferred Alternative, PANYNJ would develop a detailed, overall Health and Safety Program (HASP), which would consist of several individual HASP plans to be implemented throughout all aspects of the project's construction.

The HASP plans developed and implemented by each contractor would require that detailed work scopes be reviewed and approved by PANYNJ to ensure safety in each task, and that equipment, materials, controls, crew size, job responsibilities, operating procedures, and maintenance practices be addressed, implemented, and audited for safety. The HASP plans would identify potential safety concerns and describe methods to protect construction workers and the general public from exposure to contaminants present in air, soil, ground water, building materials, and buried structures encountered at the site. The management plans would contain the methods to be used in handling, staging, disposal, transport, and decontamination of equipment and personnel in accordance with local, state, and federal regulations. Further, the management plans would contain a list of licensed waste haulers and disposal facilities that would accept each of the above noted hazardous materials.

The HASP will include worker training and required safety courses, monitoring requirements, use of personal protection equipment (PPE), contaminant action levels, identification of potential contaminants, Soil Management Plan, Groundwater Management Plan, Dust Management Plan, development and implementation of management plans to address polychlorinated biphynels (PCBs) and asbestos, and air monitoring equipment. Further, the HASP will address preventative measures to narrow down or eliminate potential exposure pathways and corrective actions if exposure occurs. If contaminant concentrations are exceeded during construction, then all activities will cease and the appropriate remedial actions would be undertaken as noted in the HASP.

As described in Chapter 12, "Contaminated Materials," additional protocols would be established to protect the general public and the environment throughout the construction period with respect to the disturbance of any contaminants and/or hazardous materials. In addition, the

HASP plans would include and acknowledge compliance with specialized training requirements for track safety as set forth by PATH System Safety requirements for any construction along or adjacent to active PATH property. PANYNJ, through its contractors, would use preventative as well as responsive measures in managing and controlling hazards. These would include inspections, self-assessments, and testing to identify problem areas. PANYNJ would implement an audit program to ensure all contractors are in conformance with their individual HASP plans and the project-wide HASP. Contractors will also comply with safety aspects as they pertain to U.S. Department of Labor, Occupational Safety and Health Administration (OSHA) or Mining Safety and Health Administration (MSHA) regulations.

The construction of the Preferred Alternative would occur within, above, and around the temporary WTC PATH station. PANYNJ has been and would continue to develop a detailed staging plan to both maintain and protect PATH operations during the construction period. This would include a Maintenance and Protection of Traffic (MPT) plan that provides specific measures to protect riders using the temporary WTC PATH station. Specific measures may include scaffolding, safety barriers, detour routes, safety officers, and informational and directional signage. Activities that pose greater risk to PATH customers would be conducted at night or on weekends with an adjusted service schedule to ensure the protection of riders. With these measures, access to the temporary PATH station would generally be maintained throughout the construction of the Preferred Alternative.

During the construction period, PANYNJ would maintain off-site pedestrian patterns similar to current conditions in Lower Manhattan. The existing perimeter wall surrounding the WTC site would be maintained both for public viewing of the site and the protection of pedestrians. Pedestrian diversions to Cortlandt or Cedar Street would be facilitated, if necessary, with traffic control officers, signage, and barricades, focusing on the safety of pedestrians crossing Church Street. For construction activities on Route 9A associated with the Permanent WTC PATH Terminal, PANYNJ would coordinate with New York State Department of Transportation (NYSDOT) to develop a plan to maintain and protect pedestrian access during the construction period, similar to methods that would be employed for the protection of pedestrians on Church Street.

Since September 11, 2001, PANYNJ and its contractors have implemented strict security procedures for access to the WTC site. These procedures include pre-clearance and photo identification for all personnel that visit the site, checkpoints and inspections of materials being delivered to the site, and 24-hour monitoring of activities on and near the site. PANYNJ would continue to use these procedures to protect the PATH riders, the general public, and construction workers during and after construction of the Permanent Terminal.

C. OPENING YEAR (2009) AND DESIGN YEAR (2025)

The terrorist attacks of September 11, 2001 have elevated national attention toward personal safety, and the security of the Preferred Alternative and the WTC site is of paramount concern to PANYNJ. From the inception of the design process, the development of the project has included safety security operations as a fundamental planning and programming element. Plans for all aspects of train safety, station safety, and safety in other facilities are a key component of the design for the Terminal. The safety and security benefits to be provided by the project would contain pre-September 11, 2001 standard security measures such as surveillance, lighting, emergency communications, and egress, but would also include advanced systems such as structural hardening, redundancy, and air monitoring and detection systems.

PANYNJ commissioned the creation of a security master plan document. This document was developed through the partnership of a team, which consisted of PANYNJ, architects, civil engineers, geotechnical engineers, structural engineers, landscape architects, electrical engineers, mechanical engineers, fire protection engineers, security engineers, transportation and traffic engineers, and numerous other specialists. The purpose was to reach an informed consensus of rational and justifiable threats, vulnerabilities, and mitigating strategies to be included as part of the design guidelines for the Preferred Alternative and the WTC Memorial and Redevelopment Plan. Absent the Preferred Alternative (the No Action Alternative), elements of the WTC Memorial and Redevelopment Plan, including their associated security measures, would be developed at the WTC site. However, the advanced security measures intended as part of the coordinated master plan may not be fully realized.

Safety and security considerations would be embodied in the Preferred Alternative's civil designs through consideration of vehicular access, control, and careful validation of their cargo. Utility type, redundancy, locational placement, and protection would also be managed under the security master plan guidelines. Control and management of vehicular access and approach to pedestrian plazas would be carefully regulated by urban-sensitive designed streetscape. The enforcement of vehicular standoff distances to critical utilities, infrastructure, and the iconic structures would be provided through integrated site civil and landscape design elements.

Architectural designs would include the specification of façade and exterior glazing systems responsive to exceptional natural events, as well as the additional design loads created by explosive events delivered by vehicles and/or persons with the consequent capability of greatly enhancing life safety. These designs would also respond to emergency evacuation and crowd management protocols based on historical experiences, governing codes, and security master plan guidelines that acknowledge a need for anticipating the failure of normally available systems, protective designs, and human management intervention. This would be achieved by the implementation of carefully planned emergency egress, including areas of refuge, increased stair and exit path sizing, exiting route locational diversity and redundancy, airborne contaminant compartmentalization and purging, way finding clarified through sight lines and destination recognition, signage, graphics, and other remaining architectural design features.

Mechanical, electrical, and fire protection systems shall be provided to achieve an enhanced level of fault tolerance, in excess of code requirements. This would be achieved through additional pressurization and purging of pedestrian environments and the implementation of additional heating, ventilation, and air conditioning (HVAC) control zones for unique areas that would be at an elevated level of risk, including vehicle screening areas, command and control centers, car parking areas, loading docks, mailrooms, messenger centers, and lobbies. Fire protection, detection, and associated emergency voice communication systems would have enhanced fault tolerant operational capabilities through the application of redundant water sources, pumps, distribution and control apparatus, bi-directional communication systems, and linkage to backup monitor and control sources. The roof of the Terminal's east-west connection to the World Financial Center, which is below the proposed extension of Fulton Street, will be reinforced to support the future roadbed. The hardened road bed of Fulton Street would provide for enhanced security within the Terminal's east-west concourse. The road bed would protect the concourse in the event of a fire or explosion at street level.

Electronic security countermeasures, including video surveillance, intrusion detection, control of both vehicular and pedestrian access, badge/identity authentication, and emergency voice communications are envisioned to be included as part of each stakeholder occupancy

(transportation terminal, commercial, retail, hospitality, cultural, memorial, and support infrastructure), as well as being centrally coordinated so that individual stakeholder facility security systems are competently managed as part of a WTC site-wide electronic campus master plan. This would provide the opportunity for each stakeholder's investment in security systems and staffing to be added to the collective investment made by all other WTC facilities, including the Permanent WTC PATH Terminal, essentially creating an efficiently managed security precinct. This would exceed the crime prevention performance of similar security programs embodied in the Business Improvement Districts (BIDs) currently in operation elsewhere in Manhattan.

The security design criteria to be incorporated at the WTC site, including the Preferred Alternative, is based on nationally recognized and accepted standards used by the U.S. General Services Administration, U.S. Department of State, U.S. Department of Interior, U.S. Department of Justice, U.S. Department of Homeland Security, U.S. Department of Transportation, Standard for Testing and Materials, American National Standards Institute, and other similar testing agencies and standard setting institutions. Criteria will also consider principles of Crime Prevention through Environmental Design.

The entire PATH system must conform to U.S. Department of Transportation Federal Railroad Administration (FRA) standards for safety and security. The system is regularly inspected; staff is frequently trained, and safety is a key component of PATH's operating and maintenance procedures. Recently, PATH underwent close inspection of its cars, equipment, and infrastructure as part of the restoration of service to the WTC site. PANYNJ and PATH collaborated with FRA through this process and results were positive, allowing for the station's opening.

PANYNJ commissioned training and coordination of communications and life safety systems prior to the opening of the temporary WTC PATH station. Similar procedures would be conducted as part of the planning, development, and opening of the Preferred Alternative.

The Preferred Alternative would meet National Fire Protection Association (NFPA) 130 standards for fixed guideway transit systems for fire protection and egress; and PANYNJ, in coordination with city, state, and federal law enforcement agencies, would develop detailed security plans for the Terminal. It is anticipated that the PANYNJ Police Department would be responsible for normal policing of the Terminal and that the New York City Police Department (NYPD) would provide support and/or command and control for exceptional emergency situations as determined by PANYNJ and the New York City Office of Emergency Management. To increase the effectiveness of police activities, it is envisioned that the resources of the PANYNJ Police Department, NYPD, Fire Department of New York, New York City Department of Transportation, NYSDOT, Metropolitan Transportation Authority, and other established law enforcement, transportation, emergency response, and planning agencies would contribute through an interactive process of standards development and design review, as facilities emerge from their respective design phases to implementation. The intention is to provide an unprecedented level of interagency interoperability, which would be more effectively managed by the design and construction of an innovative New York City neighborhood whose conception included security and safety design principle developed by a consortium of design, security, planning, law enforcement, and emergency response professionals. ✷

Chapter 18: Agency Coordination, Process, and Public Participation

A. INTRODUCTION

This chapter presents a summary of the process used to encourage public participation performed to date for the Permanent World Trade Center (WTC) PATH Terminal environmental review, including forums for agency and public participation. This chapter also describes the various regulatory approvals that are required by federal, state, and local agencies to construct and operate the Permanent WTC PATH Terminal. Finally, contacts are provided for the solicitation of further information.

B. PUBLIC INVOLVEMENT PROGRAM

A comprehensive public involvement program has been implemented for this project. The public involvement effort has been designed to help provide complete information, be early and continuing, timely in public notice, broad in public outreach, and responsive. The public participation process is one that requires extensive and intensive outreach to private citizens, local businesses and associations, development authorities, elected officials, affected government agencies and others in New York and New Jersey.

The overriding goal of the public participation process is to engage a diverse group of public participants in order to provide timely information and solicit relevant input throughout the environmental review process. In order to best accomplish this, the following objectives have been pursued:

- Establish ongoing, inclusive and meaningful two-way communication with stakeholders and the public.
- Inform the public about the environmental review process and the role of government, stakeholders and the general public.
- Clarify the role of this project relative to other Lower Manhattan projects and studies, while at the same time coordinate outreach activities with those efforts in order to best utilize the public's involvement.

MAILING LIST

The project mailing list was developed for the distribution of outreach materials related to the environmental review process for the Permanent WTC PATH Terminal. The mailing list currently contains more than 900 addressees representing elected officials; federal, state, and local agencies; Technical Advisory Committee (TAC) members; Section 106 consulting parties; community and interest groups; local property owners and managers; and any members of the public who have requested mailings, including those who attended the public scoping meetings and public hearings on the DEIS.

FLYERS

More than 8,000 flyers advertising the October 2003 scoping meetings and June 2004 public hearings in Jersey City and Lower Manhattan were distributed at key public facilities (i.e., libraries, municipal buildings, etc.) and at several PATH stations. The flyers were also available on the project web site at www.panynj.gov/pathrestoration.com. Flyers were available in both English and Spanish.

MOBILE PUBLIC INFORMATION CENTERS

The project's outreach plan included mobile public information centers. These centers were held at PATH stations and provided easy access to interested members of the community wishing to learn more about the study and its progress. Flyers advertising public meetings were distributed at these centers and personnel from the Port Authority of New York and New Jersey (PANYNJ) and PATH were on hand to answer questions. Four mobile information centers were held in September 2003 in New Jersey to advertise the public scoping meetings. A mobile information center was also held at the temporary WTC PATH station in June 2004 to advertise the public hearing on the DEIS.

NEWSLETTERS

The first in a series of project newsletters was published in October 2003. The newsletter was distributed via the project mailing list and at the scoping meetings, as well as being made available online. The newsletters will help keep the public and other stakeholders apprised of the progress of this project and inform them of how they can stay involved.

A second newsletter was published in June 2004, concurrent with the release of the DEIS. It was distributed to the project's mailing list and was made available at the public hearings. The newsletter described the scoping process for the DEIS, the Section 106 review process, and the temporary WTC PATH station. It also provided information on the public review process for the DEIS.

WEBSITE

Information about the project has been and will continue to be available on the project's website (www.panynj.gov/pathrestoration.com). The website includes the project's environmental documents including the scoping document, the DEIS, and the FEIS. The website was also used during the project's scoping and DEIS comment periods as a medium for the public to e-mail comments. In the future, the website will provide information to the project's Section 106 consulting parties and the general public regarding construction plans and protocols as well as the Terminal's design. The site will allow for an ongoing opportunity to submit comments and contact key project representatives.

C. PUBLIC INVOLVEMENT ACTIVITIES

AGENCY AND STAKEHOLDER COORDINATION

FEDERAL INTER-AGENCY REVIEW TEAM

As described in Chapter 1, "Purpose and Need," and Chapter 2, "Project Alternatives," the U.S. Department of Transportation, Federal Transit Administration (FTA) and PANYNJ have

organized and/or participated in several efforts to coordinate the planning and environmental review of projects in Lower Manhattan. On the federal level, the FTA has formed the Interagency Review Team (IRT). An outgrowth of the Memorandum of Understanding among the federal partners (August 2002) and Executive Order 13274 on Environmental Stewardship and Transportation Project Delivery, the IRT includes various federal oversight agencies involved in the review and approval of the environmental documents for the Lower Manhattan recovery efforts. The IRT continues to coordinate on the progress and results of ongoing environmental reviews in order to communicate and resolve issues throughout the process. This forum helps to expedite the formal review of these environmental documents by the respective oversight agencies.

LOWER MANHATTAN PROJECT SPONSORS

Community involvement has been considered crucial to developing a plan that addresses community concerns while addressing the transportation needs of an ever changing and evolving Lower Manhattan. On the local level, the project sponsors for the Lower Manhattan recovery efforts have been coordinating the planning and analysis of these projects. A bi-weekly meeting is held between project sponsors including the PANYNJ, Metropolitan Transit Authority (MTA), New York State Department of Transportation (NYSDOT), New York City Department of Transportation (NYCDOT), Lower Manhattan Development Corporation (LMDC), community board members, interest groups and the consultant teams to coordinate and consolidate data collection, analyze methodologies and assumptions, impact criteria, and technical results for the environmental documents being prepared under the National Environmental Policy Act (NEPA). This proactive effort is aimed at expediting the preparation of individual documents and ensuring the consistency of the environmental findings.

As described in the DEIS, the project sponsors developed a framework for construction coordination, which included several working groups to address issues that have been identified in the individual environmental documents for the Lower Manhattan recovery projects and to implement the EPCs. The sponsors established a Schedule Working Group, a Logistics Working Group, a Traffic Working Group, and a Standards Working Group. Through this coordinated approach to the construction of individual projects, the project sponsors strove to meet or exceed the EPCs to the extent possible and to investigate and remediate issues and concerns that could arise during the construction process.

As described in Chapter 2, "Project Alternatives," Governor Pataki has established, by way of an Executive Order, the Lower Manhattan Construction Command Center. This entity will coordinate the construction of the Lower Manhattan Recovery Projects but will also coordinate any other construction projects in Lower Manhattan with a value in excess of $25 million through 2010. The Command Center will have an Executive Committee consisting of representatives from the various project sponsors, including PANYNJ, MTA, LMDC, and NYSDOT, as well as other key state and local agencies. The Command Center and its Executive Committee will be managed by an Executive Director, who will be appointed by the Governor and the Mayor.

As the entity responsible for construction coordination, the Command Center will establish a master schedule for the Lower Manhattan projects and will work with project sponsors, contractors, and the public to alleviate potential conflicts.

TECHNICAL ADVISORY COMMITTEE

PANYNJ has established a Technical Advisory Committee (TAC) for the Permanent WTC PATH Terminal. The TAC provides federal, state, and local officials and agencies with an opportunity to learn the status of the project, and it serves as a forum to provide input and raise issues of coordination between this project and the other large projects in Lower Manhattan. To date, there have been two meetings for the project, one on Tuesday, September 30, 2003 and one on Tuesday, June 15, 2004. The following is a list of agencies that have been asked to participate in the TAC.

- Battery Park City Authority
- Empire State Development Corporation
- Lower Manhattan Development Corporation (LMDC)
- Metropolitan Transportation Authority (MTA)
- MTA, New York City Transit
- New Jersey Department of Transportation
- New Jersey Transit
- New York City Department of City Planning
- New York City Department of Environmental Protection
- New York City Department of Transportation
- New York City Economic Development Corporation
- New York City Fire Department
- New York City Landmarks Preservation Commission
- New York City Mayor's Office
- New York City Police Department
- New York Metropolitan Transportation Council
- New York State Department of Environmental Conservation
- New York State Department of Transportation
- New York State Office of General Services
- New York State Office of Parks, Recreation and Historic Preservation
- North Jersey Transportation Planning Authority
- U.S. Army Corps of Engineers
- U.S. Department of Housing and Urban Development
- U.S. Department of Transportation, Federal Highway Administration (FHWA)
- U.S. Department of Transportation, Federal Railroad Administration
- U.S. Environmental Protection Agency, Region 2

OTHER AGENCY/STAKEHOLDER OUTREACH

PANYNJ Offices of Government Affairs and Priority Capital Programs continue to conduct informal briefings with elected officials, Community Board members, and other key stakeholders to provide updates on the process, and to solicit their input. Efforts to date have included formal congressional briefings, presentations to Community Board #1 and its subcommittees, informal and formal project briefings to New York City agencies, and meetings with the Lower Manhattan Transportation Task Force. PANYNJ will continue to communicate with these groups as project planning and construction moves forward.

PUBLIC INVOLVEMENT MEETINGS

PUBLIC SCOPING

Public scoping first introduced the project formally and its purpose and need to the community. The scoping document, which was prepared as part of this process, outlined the project's purpose and need, its goals and objectives, alternatives under consideration, and the framework for the environmental analysis. The scoping document for this EIS was released on September 26, 2003, and on October 8 and 9, 2003, the FTA and PANYNJ held public scoping meetings in Jersey City and Lower Manhattan to present information and solicit comments on the environmental review of the Permanent WTC PATH Terminal. The meetings were promoted through the TAC, newspaper advertisements, media releases, newsletter, mailings, the web site, and the mobile public information centers.

The public was encouraged to submit comments at the scoping meetings or by mail, phone, fax, and e-mail. The close of the public comment period was Wednesday October 29, 2003. A total of 71 people submitted comments during scoping.

The key issues raised by the public during scoping were:

- The project's role in the revitalization of Lower Manhattan;
- Coordination with LMDC and other Lower Manhattan recovery projects;
- Preservation of the footprints of the former twin towers;
- Air quality, noise, and traffic and pedestrian circulation during construction; and
- Secondary and cumulative effects during construction.

Members of the public also commented specifically on the draft scoping document and the project alternatives that were presented at the scoping meetings. Some requested additional public information such as:

- Clearer demarcation of the World Trade Center 1 and 2 footprints on any graphics;
- Identification of what elements of the station might be within the footprints; and
- Blueprints of the original PATH train configuration.

Comments from public interest groups and the New York City Department of City Planning proposed two additional alternatives. The first requested that project team consider routing a new track connection between the Downtown PATH under Fulton Street and constructing a new PATH No. 6 station. As described in Chapter 2, "Project Alternatives," this alternative was considered but was eliminated due to engineering and other constraints. The second alternative recommended that the Terminal not include a connection to Liberty Plaza. As described in Chapter 2, "Project Alternatives," of this FEIS, this has become the Preferred Alternative for the Permanent WTC PATH Terminal.

Comments received during the scoping process were addressed within the DEIS. Appendix H of this FEIS includes the list of comments and responses from the public scoping process.

PUBLIC HEARINGS ON DRAFT ENVIRONMENTAL IMPACT STATEMENT

Public hearings on the DEIS were held at City Hall in Jersey City, New Jersey on June 23, 2004 and at Saint John's University-Manhattan Campus in Lower Manhattan on June 24, 2004. The public was notified of the hearing locations, dates, and times through the variety of media including newspaper advertisements, posters and flyers at PATH stations, mobile public

information centers, and direct mailers. To maximize attendance from regional residents, stakeholders, commuters, and public officials, the meetings were held from 4PM to 8PM. PANYNJ staff made a presentation on the project at 4:30PM and 6:30PM during each of the hearing dates. A stenographer recorded all public comments, and the hearings were video taped. Presentation boards and computer animations were prepared for the public to view project plans and the findings of the DEIS, and PANYNJ and consultant staff were on hand to informally address questions.

A total of 15 persons spoke at the public hearings, and two members of the audience submitted written comments at the hearings. An additional 26 parties sent letters, e-mails, or faxes during the DEIS comment period. Comments addressed the alternatives considered for the project; methods of fare collection; integration of transit systems; air quality impacts and mitigation; preservation of historic resources; and overall project benefits. Comments made during the DEIS comment period have been summarized in Chapter 19, "Public Comments on the DEIS and Responses." The written transcript of the hearings as well as the letters, e-mails, and faxes sent during the DEIS comment period is shown in Appendix H.

THE SECTION 106 PROCESS

The National Historic Preservation Act (NHPA, 16 USC §470) of 1966 requires federal agencies to take into account the effects of their undertakings on properties either listed in or determined eligible for listing in the National Register of Historic Places. This process, commonly referred to as the Section 106 process, provides for review of any federally licensed, financed, or assisted undertaking. The FTA is the federal agency concerned in the case of the Permanent WTC PATH Terminal. In order to comply with the law, federal agencies follow Section 106 of the NHPA and their implementing regulations developed by the Advisory Council on Historic Preservation (36 CFR part 800). The process includes identifying historic properties, assessing adverse effects, and resolving adverse effects. The process involves consultation with State Historic Preservation Officers (SHPO), local governments, and members of the public.

The Section 106 review process for the Permanent WTC PATH Terminal began concurrent with its public scoping in September 2003. In order to facilitate the process for three of the Lower Manhattan Recovery Projects, FTA entered into a coordinated Section 106 review process with FHWA (lead agency for the Route 9A Project) and LMDC (lead agency for WTC Memorial and Redevelopment Plan) in December 2003. The three federal agencies jointly notified the SHPO and Advisory Council on Historic Preservation (ACHP) concerning these three Lower Manhattan undertakings and identified potential consulting parties to the Section 106 process. In January and February 2004, FTA, FHWA and LMDC hosted two meetings with consulting parties to discuss the projects and in particular the evaluation of the WTC site for eligibility for inclusion in the National Register of Historic Places. Consulting parties were also offered opportunities to comment on draft versions of the Coordinated Determination of Eligibility for the WTC site, which was issued in final form on March 31, 2004. At that time, the coordinated process effectively ended, leaving each lead agency to meet the remainder of its Section 106 responsibilities separately as appropriate to its respective undertaking.

Subsequently, the FTA has determined that the Permanent WTC PATH Terminal would have an adverse effect on the National Register-eligible WTC site and the National and State Register-eligible Hudson River Bulkhead. The FTA has also determined that the Permanent WTC PATH Terminal may have adverse effects to off-site historic resources during its construction (see Chapter 6, "Cultural Resources"). As such, PANYNJ and FTA prepared a draft Permanent WTC

PATH Terminal Finding of Effects pursuant to Section 106 of the National Historic Preservation Act, which was published as part of the DEIS. Consulting parties and the general public had the opportunity to comment on this draft Finding of Effects concurrent with the public comment period for this DEIS. FTA and PANYNJ hosted two Section 106 consulting parties meetings, one on June 14, 2004, and one on July 20, 2004. FTA and PANYNJ provided information at these meetings to further clarify the project's effects on historic resources. The consulting parties commented on the Finding of Effects and provided discussion on measures to minimize or mitigate these effects.

Following the close of the public comment period on the DEIS, FTA and PANYNJ continued coordination with the Advisory Council on Historic Preservation (ACHP), SHPO, and the other Section 106 consulting parties to develop measures to avoid, minimize, or mitigate adverse effects on the resources identified in the Finding of Effects. One consulting party meeting was held on August 19, 2004, one on November 4, 2004, and one on November 15, 2004 to solicit comments on the draft Memorandum of Agreement (MOA). Another draft version of the MOA was distributed to the consulting parties on December 16, 2004, and the consulting parties were invited to comment in writing.

The consulting parties provided input on the Draft MOA both at the meetings and in writing. The full transcripts of the meetings and the written comment letters appear in Appendix H of this FEIS. The following is a summary of the major issues raised by the consulting parties and how they are addressed in the executed MOA.

- ***Perimeter Column Remnants Outlining North Tower and South Tower Footprints and the Tower Footprint Areas:*** The treatment and accessibility of the perimeter column remnants and footprint areas in the context of the Permanent WTC PATH Terminal was raised at each of the meetings. In response, the MOA contains a set of stipulations regarding FTA and PANYNJ's commitment that, to the maximum extent feasible given project implementation requirements, the design of the Terminal will preserve in place 84 column base remnants in the North Tower and 39 column base remnants in the South Tower at the existing floor at elevation 242 (58' below Sea Level) that outline the footprints of the former Twin Towers at the WTC site and are not located in the PATH right-of-way. The MOA also sets forth the total, not-to-exceed, extent of each of the tower footprints that will be permanently occupied by any portion of the project, and specifies that the east-west pedestrian corridor will be constructed outside the North Tower footprint. The tower perimeter column bases that would remain in place but may be covered by the platform will have symbolic representation, through architectural treatments, of column remnants that may be obscured or permanently removed by the Terminal's platforms.

- ***Cumulative Effects:*** Consulting parties expressed concern about the cumulative effects of multiple undertakings in this area of Lower Manhattan on the WTC site and on other historic properties in the vicinity. Initial drafts of the MOA, as well as the DEIS and FEIS, specified that Construction Protection Plans (CPPs) would be prepared in advance of construction to ensure that buildings adjacent to areas of construction for the Permanent WTC PATH Terminal would not be inadvertently harmed by a variety of factors, including ground-borne vibration. The final MOA takes into account the need to coordinate development and implementation of the CPPs with LMDC, MTA/NYCT and NYSDOT. It also specifically provides for development and implementation of a plan for protection of historic elements of the WTC site during construction activities within the Site, including construction associated with the WTC Memorial and Redevelopment Plan and, as necessary, with the Fulton Street

Transit Center and Route 9A. The MOA also sets forth a detailed process for PANYNJ to address cumulative effects on the WTC site during design, and through the first six months of the Terminal's operation.

- ***WTC Site Artifacts:*** A number of consulting parties were concerned about "off-site" artifacts from the WTC site, many of which are in the interim care and custody of PANYNJ at Hangar 17 at JFK International Airport. The inventory and treatment of these off-site artifacts is not a part of the Permanent WTC PATH Terminal, and their possible use in the WTC Memorial will be coordinated by LMDC. However, the MOA provides a process to be followed in the event that elements now on the WTC site must be removed during construction of the Permanent WTC PATH Terminal.
- ***E-Train Subway Entrance:*** Responding to a number of comments regarding the E-train subway entrance, the MOA specifies that the remains of the pre-September 11, 2001 entrance to the E subway line from the WTC site will be incorporated, to the greatest extent possible consistent with current building codes and Americans with Disabilities Act requirements, into the new pedestrian connection between the Terminal and the subway.
- ***Recordation of the WTC site:*** Consulting parties were very interested in a comprehensive documentation of current conditions on the WTC site prior to construction, As such, recordation of the WTC site is a stipulation of the Permanent WTC PATH Terminal MOA.
- ***Continued Participation of Consulting Parties:*** Consulting parties raised concerns regarding their continued involvement following the execution of the MOA. Consistent with the regulations implementing Section 106 of NHPA, the MOA explicitly provides for continued participation of consulting parties throughout the design process and treatment plans development following the execution of the MOA.

The MOA among the FTA, ACHP, SHPO, PANYNJ, and concurring consulting parties was executed in April 2005. Chapter 6, "Cultural Resources" of this FEIS summarizes the measures specified in the MOA, which appears in full in Appendix B. A total of 69 organizations have participated in this process as consulting parties. The "List of Agencies and Organizations" section of this FEIS identifies the specific groups and individuals that have been consulting parties for this project.

D. ENVIRONMENTAL AND REGULATORY AGENCIES

During project scoping, preparation of the environmental documentation, and the public review process, PANYNJ has regularly coordinated with the relevant environmental and regulatory agencies with jurisdiction over issues of concern for the project. Further, as mentioned earlier, representatives of these and other federal, state, and local agencies are members of the project's TAC. Agencies with which consultation has occurred include:

- U.S. Environmental Protection Agency—Coordination related to EIS analyses.
- U.S. Department of Interior, U.S. Fish and Wildlife Service—Analysis of natural resources.
- U.S. Department of Transportation, Federal Railroad Administration (FRA)—As a commuter rail system, PATH operates according to policies and procedures set forth by the FRA.
- U.S. Department of Commerce, National Marine Fisheries Service (NMFS)—Analysis of essential fish habitats.

- U.S. Department of Interior—Review of potential effects on historic resources/and parklands under Section 4(f) of the U.S. Department of Transportation Act.
- Federal Interagency Review Team for Lower Manhattan Recovery Projects—Coordinated Assessment of Lower Manhattan Recovery Projects.
- Advisory Council on Historic Preservation—Review of effects on historic and archaeological resources.
- State Historic Preservation Office (SHPO) at the New York State Office of Parks, Recreation and Historic Preservation—Review of effects on historic and archaeological resources and agreements under Section 106 of the National Historic Preservation Act.
- New York State Department of State (NYSDOS)—Consistency with New York State's Coastal Management Program.
- New York State Department of Environmental Conservation (NYSDEC)—Issues related to hazardous materials, air quality, and natural resources.
- New York City and New York State Departments of Transportation (NYCDOT, NYSDOT)—Coordination related to potential construction activities. This includes detailed Maintenance and Protection of Traffic (MPT) plans that would be developed and provided to NYSDOT and NYCDOT for review and approval to ensure safe, efficient, and timely construction.
- New York City Landmarks Preservation Commission (LPC)—Review of effects on historic and archaeological resources.
- New York City Department of City Planning (NYCDCP, including in its role as administrator of the Coastal Management Program with the NYSDOS)—Review of zoning issues and consistency with New York State's Coastal Management Program and New York City's Local Waterfront Revitalization Program.

Descriptions of the relevant outreach and coordination are provided in the technical chapters of this FEIS. Copies of correspondence are included in the respective technical appendices that accompany those chapters.

E. LAWS, PERMITS, AND REGULATORY REQUIREMENTS

Numerous environmental and regulatory approvals will be required to construct the Permanent WTC PATH Terminal. A preliminary list of these permits and requirements is provided below. This list focuses on federal and state requirements, since New York State's Public Authorities Law Section 1266(8) exempts PANYNJ from local permit requirements. In addition to these items, the project must also comply with laws and policies regulating worker and public safety, and the project may require city franchises.

FEDERAL

- National Environmental Policy Act (NEPA) (42 USC §§4321 et seq.; 40 CFR Parts 1500-1508; 23 CFR Part 771; 49 CFR 622). NEPA requires federal agencies to assess the environmental impacts of major federal actions that may affect the environment before taking such an action through an environmental assessment or EIS unless the action is excluded or

exempt from NEPA. FTA is the lead federal agency for the NEPA review for the Permanent WTC PATH Terminal.

- Coastal Zone Management Act (16 USC §§1451 et seq.; 15 CFR Part 930; NY Executive Law Art. 42; 19 NYCRR Part 600). Projects affecting New York's coastal zone must be consistent with the Coastal Zone Management Act, through the New York State Department of State's Coastal Management Program and New York City's approved Local Waterfront Revitalization Plan. The New York State Department of State, in consultation with the New York City Department of City Planning, makes a determination of the project's consistency with the Coastal Zone Management Act.
- National Historic Preservation Act (16 USC §470A; 36 CFR Part 800). Projects potentially affecting historic and archaeological resources must comply with the National Historic Preservation Act Section 106 review process. FTA is responsible for carrying out the Section 106 review for the Permanent WTC PATH Terminal.
- Department of Transportation Act Section 4(f) (49 USC §303; 23 CFR 771.135). Section 4(f) prohibits the Secretary of Transportation from approving any program or project that uses any publicly owned land from a public park, recreation area, wildlife and waterfowl refuge, or historic site of national, state, or local significance unless there is no feasible and prudent alternative to the use of such land, and unless the program includes all possible planning to minimize harm to the site or resource. FTA will make the determination to reflect a Section 4(f) finding.
- Environmental Justice (Executive Order 12898 of 1994, 59 CFR 7629 (Feb. 16, 1994); 1997 USDOT "Order to Address Environmental Justice in Minority Populations and Low-Income Populations," 62 CFR 18377 (April 15, 1997)). These Orders require that impacts and benefits from a federal transportation project are equitably distributed among all population groups and that minority or low-income areas are not overburdened with the adverse aspects of proposed project alternatives. FTA is responsible for complying with this Executive Order.
- Endangered Species Act (16 USC §§1531-1544; 50 CFR Part 402). The act requires FTA to consult with the U.S. Fish and Wildlife Service for projects that may jeopardize threatened or endangered species, or destroy or adversely modify their critical habitat.
- Floodplains (Executive Order 11988 of 1977; USDOT Order 5650-2, "Floodplain Management and Protection," April 23, 1979). Federal and state agencies must regulate and limit the location of a project in a floodplain to avoid any adverse impacts associated with the occupancy and modification of floodplains. FTA will make the determination.
- Wetlands (Executive Order 11990 of 1977; USDOT Order 5660.1A, "Preservation of the Nation's Wetlands", August 24, 1978). An order for federal and state agencies to avoid the adverse impacts associated with the destruction or modification of wetlands. USDOT agencies are required to make a formal wetland finding for major projects.
- Clean Air Act and state air permits (42 USC §7506(c); 40 CFR Part 93; ECL Article 19; 6 NYCRR Parts 201). New transportation projects must conform to the applicable state implementation plan. However, as a result of the terrorist attacks of September 11, 2001, and the loss of New York Metropolitan Transportation Council (NYMTC's) files containing regional transportation and air quality data, combined with the damage incurred to the downtown mass transit system, the conformity requirements for the NYMA have been temporarily waived until September 30, 2005, pursuant to Public Law 107–230; Stat. 1469,

enacted October 1, 2002. As part of the waiver process, project sponsors are to consult with the Interagency Consultation Group (ICG) to determine if the project would be considered regionally significant and if additional data is required during the waiver period.

- Resource Conservation and Recovery Act (40 CFR Parts 260-281). Compliance is required with this Act, which regulates hazardous and solid waste activities and underground storage tanks, which may be required during project construction and operation. EPA delegates compliance to NYSDEC.
- Environmental Stewardship and Transportation Infrastructure Project Reviews (Executive Order 13274 of 2002). The Order requires federal agencies to take appropriate actions to promote environmental stewardship in the Nation's transportation system and expedite environmental reviews of high-priority transportation projects. USDOT is responsible for monitoring and reviewing the priority of transportation projects.

STATE

- State Pollutant Discharge Elimination System (SPDES) (ECL §17-0801 et seq.; 6 NYCRR Part 751). A SPDES permit is necessary for all industrial activity related storm water discharges, construction activity related water and storm water discharges, and other discharges into the waters of New York State. NYSDEC will issue SPDES permits for the project.
- Beneficial Determination (6 NYCRR Part 360) PANYNJ will apply to NYSDEC for a Beneficial Use Determination (BUD) for spoils material. Materials that will be beneficially reused and that receive a BUD designation are not under the jurisdiction of Part 360 Solid Waste Management facilities regulations.

Chapter 19: Public Comments on the DEIS and Responses

A. INTRODUCTION

This chapter summarizes and responds to all substantive comments on the Draft Environmental Impact Statement (DEIS). The public comment period for the DEIS began on June 4, 2004 with the publication of a Notice of Availability in the Federal Register. The U.S. Department of Transportation, Federal Transit Administration (FTA) and the Port Authority of New York and New Jersey (PANYNJ) held public hearings on the DEIS on June 22, 2004 in Jersey City, New Jersey and on June 23, 2004 in New York City, New York. The public comment period closed on July 21, 2004 although comments received through the publication of this Final EIS (FEIS) have been incorporated herewith.

Hard copies and/or CD-ROM copies of the DEIS were circulated to involved and interested agencies, community and civic groups, elected officials, local property owners and residents, and other interested parties. In addition, more than 400 letters were mailed to advertise the availability of the DEIS. The DEIS was posted to PANYNJ's website and copies were made available at a total of seven (7) libraries in Manhattan and New Jersey.

A flyer and newsletter advertising the public hearings was sent to the 800 persons on the project's mailing list. The public hearings were also advertised in nine (9) local newspapers including *The New York Times, The Battery Park City Broadsheet, El Nuevo Hudson,* and *The Star Ledger* beginning on June 2, 2004. The PANYNJ and its consultants conducted a mobile information center at the temporary WTC PATH station to distribute over 7,000 flyers advertising the public hearings, and PANYNJ posted notices on PATHVision and in PATH stations.

This chapter identifies the organizations and individuals who commented on the DEIS, then summarizes and responds to their comments. The comments have been organized according to the pertinent subject area with the DEIS. Where comments did not specifically pertain to the scope of the Permanent WTC PATH Terminal, they have been grouped as "Other." All commenters are noted but individual comments have been consolidated where appropriate. The transcripts of the public hearing and all written comments have been included in Appendix H of this document. Where revisions to this document have been made to address specific public comments as well as new or refined information about the project, text has been double-underlined in this Final Environmental Impact Statement (FEIS).

B. LIST OF COMMENTERS

A total of 41 parties commented on the DEIS. Fifteen parties spoke at the public hearings for the DEIS. The remaining comments were mailed, e-mailed, or faxed to PANYNJ during the public comment period. The following is a list of the commenters, their affiliation, and the date and method in which their comments were received.

- Adler, Steve. Speaker at public hearing dated June 23, 2004.

- Anonymous 1. Facsimile dated June 16, 2004.
- Ayer, Sarah M, AT&T. Letter dated July 21, 2004.
- Bachmore, John, Verizon Communications, Inc. Letter dated July 21, 2004.
- Barzilai, Tal, E-mail dated July 21, 2004.
- Blackman, Laura, Hudson River Park Trust. E-mail dated July 8, 2004.
- Bowen, Douglas John. Speaker at public hearing dated June 22, 2004.
- Butziger, Alexander. E-mail dated July 21, 2004.
- Carey, Timothy S., Battery Park City Authority. Letter dated July 14, 2004.
- Coangelo, Kelly. Speaker at public hearing dated June 23, 2004.
- Epstein, Louis, The World Trade Center Restoration Movement. Speaker at public hearing dated June 23, 2004 and letter dated July 21, 2004.
- Gardner, Anthony, Coalition of 9/11 Families. Letter dated July 27, 2004. (Comments are herein noted as Gardner.)
- Gardner, Anthony, Coalition of 9/11 Families; Fetchel, Mary, Voice of September 11; Sally Regenhord, Sally, Skyscraper Safety Campaign. Letter dated July 16, 2004. (Comments are herein noted as Gardner et al.)
- Gaull, Marilyn. E-mail dated July 6, 2004.
- Goetz, Bernard. Speaker at public hearing dated June 23, 2004; written comments dated June 23, 2004.
- Gorsky, Steven, Barclay's. Written comments dated June 16, 2004.
- Haikalis, George, Regional Rail Working Group. Speaker at public hearing dated June 23, 2004; written comments dated June 23, 2004; e-mail comments dated August 4, 2004.
- Hargrove, Robert W., U.S. Environmental Protection Agency. Letter dated July 21, 2004.
- Hensley, Jen, The Alliance for Downtown New York, Inc. Speaker at public hearing dated June 23, 2004; written comments dated June 23, 2004.
- Hemric, Benjamin. Letter dated July 20, 2004.
- Jackson, Don, Local Union #3 IBEW. Written comment sheet dated June 23, 2004.
- Kornfeld Jr., Robert, The Historic Districts Council. Written comments dated July 6, 2004.
- Lachman, Seymour P., New York State Senate District 23. Letter dated July 21, 2004.
- Lictro, John. D. E-mail dated July 20, 2004.
- Love, Bill, Coalition to Save West Street. Letter dated July 5, 2004.
- Lustbader, Ken, Lower Manhattan Emergency Preservation Fund. Speaker at public hearing dated June 23, 2004; written comments dated June 23, 2004.
- Mason, Alan, Local Union #3 IBEW. Speaker at public hearing dated June 23, 2004.

- McArdle, Frank, General Contractors Association of New York. Speaker at public hearing dated June 23, 2004.
- Morrow, Yvonne. Written comments submitted on July 21, 2004.
- O'Shea, James P. Facsimile dated June 28, 2004.
- Olsen, Olaf, Local 14, Union 1456. Speaker at public hearing dated June 23, 2004.
- Orkin, Jenna. Speaker at public hearing dated June 23, 2004.
- Ormsby, Chris, Local Union #3 IBEW. Speaker at public hearing dated June 23, 2004.
- Papp Jr., Albert, New Jersey Association of Railroad Passengers. Speaker at public hearing dated June 23, 2004; e-mail comments dated August 4, 2004.
- Pasternack, Scott. E-mail dated June 21, 2004.
- Sanchis III, Frank E., Municipal Art Society; Breen, Peg, New York Landmarks Conservancy; Burnham, Bonnie, World Monument Fund; Merritt, Elizabeth, National Trust for Historic Preservation; Heyl, Scott, Preservation League of New York State. Letter dated July 8, 2004. ((Comments are herein noted as Sanchis III et al 1.)
- Sanchis III, Frank E., Municipal Art Society; Fenollosa, Marilyn, National Trust for Historic Preservation; Breen, Peg, New York Landmarks Conservancy; Burnham, Bonnie, World Monument Fund; Merritt, Elizabeth, National Trust for Historic Preservation; Heyl, Scott, Preservation League of New York State. Letter dated August 2, 2004. ((Comments are herein noted as Sanchis III et al 2.)
- Scian, Paul. E-mail dated June 21, 2004.
- Stilwell, David A., U.S. Department of the Interior, Fish and Wildlife Service. Letter dated June 15, 2004.
- Sulphin, Amanda, New York City Landmarks Preservation Commission. Letter dated June 17, 2004.
- Taylor, Willie R., U.S. Department of the Interior. Letter dated July 30, 2004.
- Todorovich, Petra, Regional Plan Association. Speaker at public hearing dated June 23, 2004.
- Yaro, Robert D., Regional Plan Association. Letter dated July 21, 2004.

C. COMMENTS AND RESPONSES

PURPOSE AND NEED

Comment 1: The World Trade Center Transportation Hub will restore long-term access to Lower Manhattan and connectivity to the New York City subway system, contributing to the revitalization and economic recovery of Lower Manhattan. The Santiago Calatrava design of the PATH Station could not be more fitting for the site of the former World Trade Center, a bird-like, fully functional structure with movable wings that look ready to soar. The Permanent WTC

PATH Terminal will be a grand and proper entrance to Lower Manhattan. It will create countless temporary construction jobs and countless permanent jobs, and its timely completion will demonstrate America's strength in the wake of tragedy. (Olsen, Todorovich, Ormsby, Mason, Hensley, Jackson, Carey)

Response: Comment noted.

PROJECT ALTERNATIVES

Comment 2: Since master plan seems to be in flux it may be prudent to wait upon finalization before building this hub.(O'Shea)

Response: As of September 15, 2003, the Lower Manhattan Development Corporation (LMDC), PANYNJ, and Studio Daniel Libeskind agreed to a plan for the programming of commercial, retail, cultural, and transportation spaces within the WTC site. As the site's owner, PANYNJ continues to be involved as plans move forward to ensure that the programming of uses on the WTC site can fully accommodate the spatial and infrastructure needs of the Permanent WTC PATH Terminal.

Comment 3: The Permanent WTC PATH Terminal needs at least two bathrooms for the convenience of the public. (Anonymous)

Response: The design of the Terminal's interior facilities will be closely coordinated with the amenities provided as part of the WTC retail complex. It is anticipated that adequate restroom facilities will be provided to accommodate both transit commuters and shoppers who visit the WTC Transportation Hub and its adjoining retail stores.

Comment 4: Drawings of the Permanent WTC PATH Terminal do not show integration of the existing subways into a regional subsurface transportation hub. Is the future integration of the various subway stations and PATH station with subsurface people movers no longer planned? If so, it would be a tremendous loss to the rebirth and economic vitality of both downtown and NYC as a whole. (Scian)

Response: Figures 2-4 and 2-5 show the all-weather connections between the Permanent WTC PATH Terminal and the Dey Street Concourse of MTA/NYCT's Fulton Street Transit Center (2, 3, 4, 5, A, C, E, J, M, and Z trains); MTA/NYCT's Cortlandt Street (R and W) station; MTA/NYCT's Cortlandt Street (1 and 9) station; and MTA/NYCT's World Trade Center (E) station. The Terminal also provides a connection to the trans-Hudson ferry terminal at Battery Park City. A multi-agency feasibility study completed in May 2004 identified two alignments for a possible Jamaica-JFK-Lower Manhattan transit route. The terminals of these proposed alignments were proximate to the Permanent WTC PATH Terminal. However, future planning and design efforts will refine these initial

concepts and could result in a new terminal location. It is premature to make specific design commitments for the integration of the Permanent WTC PATH Terminal and the Jamaica-JFK-Lower Manhattan Terminal; however, PANYNJ will coordinate with the other sponsors of the Jamaica-JFK-Lower Manhattan project as its future planning and design efforts move forward. Overall, the PATH Terminal will improve connectivity and wayfinding for the various transit services in the vicinity of the WTC site and Lower Manhattan in general.

Comment 5: It is imperative that the new station avoid hidden spaces, narrow corridors, steep stairwells, low ceilings and poor ventilation, all mistakes of the pre-September 11, 2001 PATH Terminal—the past station that we now have an opportunity to correct. (Todorovich)

Response: The preliminary design of the Preferred Alternative calls for the use of natural light on all levels, for the use of modern heating, ventilation, and air conditioning systems, and for the creation of well lit, visually-appealing pedestrian corridors that provide for safe and convenient circulation throughout the complex.

Comment 6: The design is too costly at $2 Billion. (Butziger; Epstein; O'Shea; Barzilai)

Response: In addition to the elements of the Permanent WTC PATH Terminal, such as tracks, platforms, mezzanine, concourses, and the Terminal Hall, the Preferred Alternative includes site preparation and repair work that is needed to support the WTC site's overall redevelopment. This includes repairs to portions of the WTC bathtub walls and portions of the demolition within the eastern portion of the WTC site. FTA and PANYNJ may fund these elements as part of the Permanent WTC PATH Terminal project.

Comment 7: The Libeskind plan will make the station nearly impossible to use. (Barzilai)

Response: FTA, PANYNJ, MTA, and the project's design team have been coordinating to develop a Terminal plan that will provide for easy navigation by its users. This plan has been closely coordinated with master planning for the WTC site and will result in the creation of an east-west concourse between the World Financial Center and the Dey Street concourse of the Fulton Street Transit Center and a north-south concourse between the World Trade Center (E) subway station and the southeast quadrant of the WTC site. The east-west and north-south concourses will cross within the transit hall. The concourses will have visual access to the outdoors to help guide pedestrians as they travel through the complex, and wayfinding signage will be provided throughout the complex.

Although being planned separately, the Permanent WTC PATH Terminal elements have been and will continue to be well coordinated with the WTC

Memorial and Redevelopment Plan to ensure easy access to the memorial, cultural centers, offices buildings, and retail that will be constructed on the WTC site. The concourses of the Terminal will provide sub-grade access to most of the uses planned for the site.

In addition, elements of the Permanent WTC PATH Terminal and the WTC Memorial and Redevelopment Plan will provide superior above grade access to PATH as compared to the pre-September 11, 2001 condition. The newly constructed transit hall in combination with the newly constructed Fulton and Greenwich Streets through the WTC site will provide much better visual and physical access to PATH and MTA/NYCT subway stations than the plaza level of the pre-September 11, 2001 WTC complex.

Comment 8: A location to the east of the planned Terminal in the original location of the Hudson Terminal would have greater connectivity to financial district, Fulton Street Transit Center, and transfer point to N and R subway line. (Epstein, O'Shea)

Response: As described in Chapter 2, "Project Alternatives," of the DEIS, the reconstruction of a Terminal immediately west of Church Street would be physically closer to MTA/NYCT"s Cortland Street (R and W) station and the Financial District. However, given the depth of the PATH platform level, a terminal at this location would require a less favorable pattern of vertical circulation as compared to the Preferred Alternative. Under the Preferred Alternative, patrons ascend toward street-level in their direction of travel. Thus, although the platforms are physically further from the Corlandt Street subway station and the Financial District, the ascension from platform level will be similar.

Comment 9: The Hudson River Park Trust requests to be included in any discussions involving the exact placement/location of pedestrian bridges, escalators and/or staircases adjacent to the Hudson River Park, which includes the bikeway west of Route 9A. (Blackman)

Response: The pedestrian bridge over Route 9A was studied as an option to a subgrade concourse. However, subsequent to the publication of the DEIS, PANYNJ has selected the sub-grade concourse as a component of the Preferred Alternative. However, PANYNJ will coordinate the location of the future entrance to the concourse with affected property owners including Brookfield Properties, the Battery Park City Authority, Hudson River Park Trust, and the New York State Department of Transportation (NYSDOT).

Comment 10: The success of Lower Manhattan's revitalization will depend greatly on the quality of the pedestrian experience at street level; therefore, PANYNJ should

pay great attention to the design of the public places surrounding the PATH pavilion as well as the public spaces throughout the WTC site. (Todorovich)

Response: PANYNJ and LMDC have been coordinating to develop design guidelines for the buildings and open space planned for the WTC site, including the Permanent WTC PATH Terminal. The approved Master Plan for the WTC site includes more than 7 acres of new open space as well as a streetscape plan for the extension of Fulton and Greenwich Streets. The proposed plaza adjacent to the Preferred Alternative's transit hall will comply with the design standards set forth for the open space contained in the approved Master Plan.

Comment 11: The Permanent WTC PATH Terminal is supposed to be a full-service hub, but on the proposed site plan both Church and Fulton streets are narrow without room for bus parking. Site plan changes should be implemented that widen Fulton and Church streets to provide adequate room for bus parking. (Goetz)

Response: The dimension of Church Street is not being changed as part of the World Trade Center Memorial and Redevelopment Plan or Permanent WTC PATH Terminal projects. Although not a part of the Permanent WTC PATH Terminal project, Fulton Street is being proposed as a new 30-foot, two-way roadway that adheres to the street grid east of Church Street. It is anticipated that buses will continue to operate along Church Street; however, at this time, a formal plan for routes along Fulton Street has not been decided.

Comment 12: The Permanent WTC PATH Terminal would be more environmentally appropriate if it did not seek to accommodate the Daniel Libeskind site plan. A new transportation system should be with the aim of furthering the "devehicularization" of Lower Manhattan, not opening more streets. Scrapping the official plan in favor of one centered on fewer taller buildings which would have their construction impact more localized and more in the spirit of what was destroyed in 2001 would be more appropriate. A more understated and physically responsible terminal would free valuable public resources for better use of the site. (Butziger; Epstein; Lictro)

Response: The scope of this environmental review process does not include the programming of streets and buildings within the WTC site. The plan for the Permanent WTC PATH Terminal incorporates pedestrian connections that will not only serve PATH users but will also provide access to, from, and within the WTC site for residents, workers, and visitors. The creation of a grand transportation hall will provide for a highly visible gateway to a revitalized Lower Manhattan.

Comment 13: The alternative with the Liberty Plaza connection is desirable. Prior to September 11, 2001, more than 40 percent of PATH users exited the WTC site

at the southeast corner, resulting in traffic and pedestrian congestion during rush hours. (Coangelo; Morrow)

Response: Although it is projected that 40 percent of the future PATH users will exit the Terminal in the direction of the Financial District, the Terminal with a Liberty Plaza Connection has not been selected as the Preferred Alternative for the Permanent WTC PATH Terminal. During and after the public comment period on the DEIS, FTA and PANYNJ considered local government and community concerns that the Liberty Plaza Connection would detract from the street-life and retail vitality of Lower Manhattan. Furthermore, the Terminal with a Liberty Plaza Connection was anticipated to result in higher or more intense air quality, noise, and vibration impacts during the construction period than the Preferred Alternative. Although additional pedestrian mitigation will be required with the Preferred Alternative, it has been determined to have greater short-term benefits to the community than the Terminal with a Liberty Plaza Connection Alternative.

Comment 14: While the EIS has demonstrated poor pedestrian levels of service at Church and Liberty streets without the Liberty Plaza Connection, the proposed mitigation measures of widening sidewalks and crosswalks are, in fact, extremely desirable. The Liberty Plaza connection if built would undermine the viability of street level retail. The Liberty Plaza connection would also require the appropriation of public open space in Liberty Plaza and would cost $81 million, which is not justified by its relatively slim benefit. (Todorovich)

Response: FTA and PANYNJ propose a Terminal without a Liberty Plaza Connection Alternative for the Permanent WTC PATH Terminal based on comments received during the public review of the DEIS. The selection of this alternative considered all of the issues raised by the above comment.

Comment 15: The No Build Alternative does not restore the capacity that existed previously nor does it enhance service to New Jersey. (McArdle)

Response: Comment noted.

Comment 16: The description of the No Action Alternative states that the temporary station would remain in operation until 1) its operation would be precluded by elements of the WTC Memorial and Redevelopment Plan, 2) it cannot safely accommodate passenger demand, or 3) its exceed its useful life. Since the LMDC has not yet completed detailed design, FTA should coordinate to ensure that their design leaves the option for future improvements to the temporary facility as to not limit alternatives for the Permanent WTC PATH Terminal. (Gardner)

Response: The No Action Alternative was prepared assuming the implementation of the September 15, 2003 master plan for the WTC site. The master plan has programmed spaces for the site, including the memorial and a PATH Terminal. As an independent action, this Environmental Impact Statement must consider the other proposed uses of the WTC site as part of the "Future Common to All Alternatives" for a Permanent WTC PATH Terminal. As such, the memorial is considered as part of the background condition in the location and configuration proposed in the September 15, 2003 Master Plan. The current, temporary PATH facility was constructed prior to the implementation of the master plan, and it cannot accommodate construction above its mezzanine level. Furthermore, the current alignment and configuration of PATH tracks and other PATH infrastructure within the west bathtub limits the placement of the memorial and memorial-related uses. Thus, certain elements of the temporary station must be removed or altered to successfully accommodate all of the uses intended for the WTC site as part of its approved Master Plan.

Comment 17: The EIS should reconsider a proposal to construct a physical track connection between PATH and the New York City Transit (MTA/NYCT) No. 6 Lexington Avenue subway line. This would require that PANYNJ and MTA/NYCT build a track, 3,000 feet in length, between the now refurbished PATH line and the No. 6 local subway in concert with the rebuilding of the World Trade Center site. Despite the comments expressed in the DEIS and correspondence with PANYNJ, we believe that construction of either a track connection or an across the platform transfer be named a viable option to enhance Trans-Hudson mobility and provide new transportation pathways to the residents of both New Jersey and New York. (Papp, Jr., Haikalis, Bowen)

Response: As described in Chapter 2, "Project Alternatives," and in Appendix H-1, "Response to Comments on the Draft Scope," the proposed direct track connection between PATH and MTA/NYCT's 6 subway line (Lexington Avenue Local) was eliminated from further consideration following scoping for the Permanent WTC PATH Terminal. The decision to eliminate this alternative was based on its cost, its engineering feasibility, and on its potential construction-period and long-term effects to the environment. Furthermore, a planned connection between PATH and the Dey Street concourse of the Fulton Street Transit Center will allow for a transfer between PATH and MTA/NYCT's 4 and 5 subway lines, which provide express service along Lexington Avenue to Manhattan's east side, and the recently approved Second Avenue Subway would also link between Lower Manhattan and the Upper East Side.

Comment 18: FTA, PANYNJ, and the other Lower Manhattan project sponsors should establish a coordinated planning approach to the World Trade Center Memorial

and Redevelopment Plan, the Route 9A Project, the Permanent WTC PATH Terminal, and the Fulton Street Transit Center. (Ayer; Carey)

Response: While planning for their independent projects, PANYNJ, MTA, LMDC, and NYSDOT have been continuously coordinating project designs, construction, and environmental review. For the Permanent WTC PATH Terminal, this coordination has led to modifications in the design and location of the Terminal's ventilation structures; accommodations within the concourse level to address modifications in the WTC Master Plan; a coordinated approach to design guidelines for the Terminal and the FSTC's Dey Street Concourse; a coordinated Determination of National-Register eligibility for the WTC site; and a coordinated set of Environmental Performance Commitments and refined mitigation measures. This coordinated planning will continue throughout design and construction of the Preferred Alternative via mediums such as the Lower Manhattan Construction Coordination Group and the Lower Manhattan Construction Command Center.

Comment 19: The DEIS does not seem to explain why a more permanent version of the current temporary terminal, one that would be in essence an upgrade of the pre-September 11, 2001 terminal concept but would fit into the present day plans for the site, was not analyzed for its environmental impacts and used as a point of comparison with the proposed action. (Hemric, Gardner, Kornfeld)

Response: Chapter 1, "Purpose and Need," describes various deficiencies of the temporary WTC PATH station over the long-term. The Permanent WTC PATH Terminal will reuse elements of the temporary station, where possible. However, the station would not allow for development above, as is planned for the WTC Memorial and Redevelopment Plan nor would it provide for sufficient access and egress points to meet growth. Furthermore, the temporary station would not allow for 10-car service on PATH's Newark-WTC Line nor sufficient platform capacity as planned to meet ridership growth. Thus, an expanded facility is needed to ensure the long-term accessibility and viability of PATH service to Lower Manhattan.

Comment 20: The DEIS does not evaluate the many feasible and constructible design alternatives that would result in the avoidance or reduction of effects to historic properties. The evaluation of alternatives to avoid or minimize Project impacts to the E-train passageway is an excellent example of alternatives that should be considered in regard to other historically significant features on the WTC site, notably the tower footprints. (Gardner, Sanchis III et al 2)

Response: The EIS considers alternatives for a Permanent WTC PATH Terminal and their potential effects. Design modifications have been proposed as part of the project's Section 106 consultation process. These modifications have been

implemented through the Project's Memorandum of Agreement and have been incorporated into the Preferred Alternative presented in this FEIS.

Comment 21: The DEIS should have considered an alternative that would not include a fourth platform. The DEIS should examine the degree to which this relatively modest increase in peak hour ridership can be accommodated through improved signalization, use of 10-car PATH trains, lengthening of platforms beyond pre-September 11, 2001 lengths, widening of platforms beyond pre-September 11, 2001 widths, and an increase in the size, number, and capacity of vertical elements beyond pre September 11, 2001 levels. These measures could preclude the need for a fourth PATH platform, which would reduce the project's effects on the Tower footprints. (Gardner, Epstein, O'Shea)

Response: The Preferred Alternative is being planned to support the PATH's system-wide improvements, PATH's operating requirements, and future ridership demand. Each of these factors results in specific requirements for the design of the Terminal's platforms and tracks, and as such, it has been determined that a 5-track, 4-platform station is needed. This configuration was selected after a careful consideration of several track and platform layouts as detailed in Appendix C of this FEIS.

PATH will implement improvements to increase capacity on trains operating between Newark and the WTC, by increasing their length from 8 to 10 cars. Not only will this improvement require that the WTC Terminal support 10-car operations but a consequence will be that more people will use the WTC PATH Terminal's platforms during peak travel periods.

All new PATH cars will have 3-doors per side allowing PATH to retire the portions of its current fleet with 2-doors per side. Three-door cars will decrease the boarding/alighting times of trains by 50 percent, which will improve dwell times at intermediate stations along the PATH route and could reduce the overall run time of trains. However, the new cars are not expected to improve the platform clearance time for passengers since they will not directly affect platform area or the provision or operation of stairways and escalators.

While PATH currently maintains 3-minute headways on its Newark-WTC Line and 4-minute headways on its Hoboken-WTC Line during portions of the peak hour, Communication-Based Train Control (CBTC) will facilitate such headways over a longer period with greater reliability and less potential for delays. CBTC in conjunction with the 10-car train program will have the ability to increase the throughput of the PATH system, to meet or exceed ridership demand and provide a higher frequency of service at the WTC Terminal than before September 11, 2001. As such, platforms at the WTC Terminal will need to clear more swiftly in the future in order to maintain safe and efficient operations.

PATH must plan for failure management to maintain reliable, on-time peak period service. Because the WTC is a terminal station, trains dwell for short periods to maintain the operating schedule. Thus, to maintain the headway and allow for the arrival of a subsequent train, PATH requires two tracks for each the Hoboken-WTC and Newark-WTC Lines. In the event that a train becomes disabled, a fifth track is needed. The fifth track allows the disabled train to remain in the Terminal while the remaining four actives tracks can be used to continue service.

PATH has limited capacity for train storage at its Newark, Harrison, and Journal Square Yards. Therefore, PATH would use the WTC Terminal for the overnight storage of 6 Hoboken-WTC trains. Four tracks are required for this overnight storage and a 5th track is needed for revenue service on the Newark-WTC Line. The overnight storage of Hoboken-WTC trains at the WTC Terminal would allow for a more efficient ramp-up to AM peak period revenue service and decreases the potential for weather-related delays on the Hoboken-WTC Line.

A principal consideration for the planning of the Terminal is the ability of platforms to safely accommodate peak period ridership. Because PATH is primarily a commuter system, the platform design must accommodate both AM and PM peak patterns of travel.

In the AM peak hour, trains unload passengers to the platform who must then ascend to mezzanine level. For this condition, the principal design criterion is the targeted time period within which all passengers exiting a train alight from the platform. As stairways and escalators become congested, passengers queue at the foot before they can ascend. Therefore, to avoid a lengthening of this back-up, it is important that all passengers clear the platform before arrival of the next train. The Transit Capacity and Quality of Service Manual states that a platform (and vertical circulation) should be planned to ensure full clearance of the platform before the next train arrives. However given that passengers may not use or may not be able to use all available exits, a safety factor of 20 to 30 percent is applied. Thus, a platform should clear fully within 70 to 80 percent of the scheduled headway.

The proposed frequency of Newark-WTC Line service requires that its platform clear within 126 to 144 seconds. However, based on projected ridership, a single Newark-WTC platform would require 213 seconds to clear. Thus, two Newark-WTC Line platforms are needed to meet platform clearance guidelines. A single Hoboken-WTC platform is sufficient to meet platform clearance criteria.

For the PM peak period, the planning of the platforms must also consider failure management in the event of a missed headway and subsequent delay in service. Thus, the platform must provide for adequate room to queue passengers waiting for the next arriving train.

Given ridership levels in 2025 and level of service standards, a minimum 15,264 square feet of platform area would be required for the Newark-WTC service in the event of a missed headway while 10,385 square feet would be required for the Hoboken-WTC service. However, accounting for the unusable areas of the platform (e.g., spaces occupied by escalators and elevators and the safety buffer along the platform edge), the Terminal's platforms would each provide for an effective area of 10,416 square feet. Thus, a single platform would be adequate for the Hoboken-WTC Line but more than one platform would be needed for Newark-WTC Line.

In order to maintain temporary PATH service during construction of the Preferred Alternative, PANYNJ would not relocate the existing PATH tracks. As such, Platform A cannot be widened beyond its current configuration, which is not adequate for normal revenue service. Since three full-size platforms are needed for peak period service, the Preferred Alternative would include a total of 4 Platforms. The 5 tracks that are currently part of the temporary station would be retained in their current alignment, which is adequate to meet PATH's operating requirements.

Comment 22: PANYNJ should not exclude other alternatives such as platforming on a higher level or east of the slurry wall, based on a subjective judgment on cost, or because it would necessitate design modifications. (Kornfeld)

Response: Platforming at a higher level is not feasible within the WTC "Bathtub" since there would not be sufficient space between the projections of the Hudson River tunnels and the Terminal to achieve PATH's design guidelines for grade and curvature.

As described in Chapter 2, "Project Alternatives," PANYNJ explore four alternative locations for the Permanent WTC PATH Terminal: Location 1, WTC "Bathtub"; Location 2, Church Street; Location 3, Broadway-Nassau; and, Location 4, Vesey Street. Locations 3 and 4 were determined to be flawed since they would fully disrupt temporary PATH service during construction. Furthermore, Location 3 would not meet the operational requirements for PATH. Locations 1 and 2 were evaluated more closely. Location 1 was considered advantageous for constructability, cost, and customer wayfinding, but it would result in a headhouse within the planned WTC Memorial zone. Location 2 would maximize train operations and would not require a headhouse within the Memorial zone, but it would have an inconvenient means of vertical circulation, would require the reprogramming of uses on the WTC site, and may have resulted in adverse contextual effects on the planned Memorial.

PANYNJ considered the advantages of Locations 1 and 2 and developed a "hybrid" alternative. The "hybrid" alternative combines the subgrade platform and mezzanine levels within the WTC bathtub with an above-grade headhouse east of MTA/NYCT's 1 and 9 subway line. It provides for the constructability,

cost, and wayfinding benefits of Location 1 without a headhouse in the Memorial zone. Because the platform and mezzanine levels would be located within the WTC bathtub, subgade levels east of MTA/NYCT's 1 and 9 line would be available for building services. This would eliminate the adverse contextual impacts to the Memorial zone that may have occurred with Location 2. PANYNJ advanced the "hybrid" alternative for detailed study in the Project's Draft and Final EIS.

Comment 23: PANYNJ should seriously consider a pedestrian bridge over West Street as an additional means to provide all-weather access between the World Financial Center and the Permanent WTC PATH Terminal. The bridge would supplement the proposed Route 9A connection. (Love)

Response: As described in Chapter 2, "Project Alternatives," a pedestrian bridge would not have the same level of customer convenience as a subgrade concourse since additional vertical moves would be required to travel between PATH and the WFC and Battery Park City. Furthermore, the subgrade concourse could fully accommodate the anticipated demand; thus, additional access across Route 9A is not considered necessary as part of the Preferred Alternative.

Comment 24: The DEIS discards Location 1, WTC "Bathtub", in favor of the Terminal with Liberty Plaza Connection ("Hybrid")Alternative despite the fact that the latter would be more expensive, require a longer construction duration, would have more below-grade infrastructure in the WTC bathtub, and would not allow for as much commercial development on the WTC site. The Location 1 alternative, which would not impinge upon the footprint of One World Trade Center is clearly "feasible" and should be considered as part of the DEIS. (Gardner)

Response: Location 1 would not meet the Purpose and Need of this project since 1) it would have 3 platforms and 5 tracks, which would not be adequate to serve future ridership on the PATH system and 2) its above-grade structures would be located west of Greenwich Street within the memorial zone, which is inconsistent with the WTC Memorial and Redevelopment Plan. As defined in Chapter 1, "Purpose and Need," the Preferred Alternative must meet the project's purpose and need. Specifically, Location 1 would not meet the following objectives:: Provide for additional capacity to support ridership growth; improve street-level visibility and access; construct a facility that is coordinated with the master plan for the WTC site; provide for connections to future WTC buildings and facilities, including the memorial; and coordinate PATH facilities with other sub-grade uses on the WTC site.

Comment 25: The encroachment of the upper level of the PATH station over the footprints and the potential of a support column within the footprints is not acceptable. (Kornfeld)

Response: As stated in the executed Memorandum of Agreement for the Permanent WTC PATH Terminal, the east-west pedestrian concourse to the World Financial Center would be designed and built in a manner that avoids the column remnants projecting above the concrete slab that outline the north perimeter of the North Tower. This corridor would be at least five (5) feet outside the North Tower footprint as measured from the center line of each projecting column base to the face of the nearest structural support wall.

The mezzanine level would be fully supported by the platform level below. As stated in the executed Memorandum of Agreement, the total extent of the North Tower footprint at this to be permanently occupied by any portion of the Project will be approximately 1,600 square feet and will not exceed 4 percent of the North Tower footprint area. The total extent of the South Tower footprint to be permanently occupied by the mezzanine will be approximately 21,615 square feet currently occupied by the WTC PATH facility, plus an additional 2,000 square feet required by the Project, and will not exceed 53 percent of the South Tower footprint area.

Up to a total of 5 column bases in the North Tower and up to a total of 3 column bases in the South Tower may be temporarily or permanently removed to construct PATH Platform D. Where Platform D would intersect the northeast corner of the North Tower footprint, the platform would be clear of vertical obstructions and architectural treatments would be used to symbolically represent the location of the footprint.

In addition, up to 4 column bases in the North Tower could be temporarily removed to install the foundation for the Terminal's support column. Those column bases that remain in situ undisturbed or are temporarily removed and returned to their original locations would be accessible following the completion of these foundations.

CONSTRUCTION METHODS AND MATERIALS

Comment 26: The construction of the Permanent WTC PATH Terminal should be coordinated by the forthcoming Lower Manhattan Construction Command Center. It is critical that issues such as worker transportation to and from the construction site, permitting, movement of materials and other logistical concerns be coordinated with the many other development projects happening in Lower Manhattan at the same time. (Hensley; Morrow)

Response: As part of the Lower Manhattan Construction Coordination Group, PANYNJ is working closely with the other Lower Manhattan Recovery Project sponsors to develop coordinated plans for individual project construction. The construction of the Permanent WTC PATH Terminal will be undertaken according to the coordinated efforts of the Lower Manhattan Construction Coordination Group and under the direction of a Lower Manhattan Construction Command Center.

(Refer to Chapter 3, "Construction Methods and Materials," for a description of the Lower Manhattan Construction Coordination Group and the Lower Manhattan Construction Command Center.)

Comment 27: Construction of the Permanent WTC PATH Terminal should occur with minimum disruption to existing PATH service, particularly during the weekday rush hours. (Hensley)

Response: PANYNJ has made provisions to allow for the uninterrupted operation of temporary PATH service during peak periods while the Permanent WTC PATH Terminal is under construction.

Comment 28: PANYNJ and the other Lower Manhattan project sponsors should work with the construction community to develop and implement noise plans and other protocols that will allow construction to move forward in an environmentally sound fashion. (McArdle)

Response: As part of the Lower Manhattan Construction Coordination Group, PANYNJ is and will continue to work closely with the other Lower Manhattan Recovery Project sponsors to develop coordinated noise monitoring and mitigation plans to alleviate potential impacts during the Preferred Alternative's construction.

To mitigate the Preferred Alternative's construction period noise impacts, PANYNJ would require contractors to use specific equipment during phases of construction to reduce noise levels below the FTA impact criteria. During the permanent track, platform, and mezzanine construction contractors would be required to use Impact wrenches with noise emission level of 82 dBA at 50 ft^2 and mufflers on pavement breaker cylinder. During the construction of the east-west concourse, contractors would be required to place drill inside acoustical enclosure. Although not required for the Preferred Alternative, PANYNJ is coordinating with the other Lower Manhattan Recovery Project sponsors to explore additional construction noise mitigation measures. These include:

- The use of acoustic barriers and walled enclosures around certain construction activities. Noise tents/enclosures could be used around workers using jackhammers. A temporary noise barrier of 20 feet in height could be installed along the fence line/property line of the Project Site to reduce noise levels. In addition, temporary barriers, such as wood panels on top of Jersey barriers could be positioned adjacent to and moved along slurry wall and other construction operations, etc.
- The placement of construction equipment in shielded locations, such as below grade in the Project Site, if possible.
- The installation of silencers on jackhammers, air compressors, generators, light plants and cranes to reduce noise levels at specific locations (e.g., adjacent to existing residential uses).

- The use of electrically operated equipment, rather than combustion equipment, wherever possible.
- The use of soil beds, timber planking and/or exterior rubber lining on truck body and aluminum carrying case to reduce rock impact noise during truck load/unloading operations.
- The use of drive-through street-level truck enclosures for truck loading and unloading.
- The use of sheds/enclosures at concrete pump sites during concrete truck unloading, and the placement of most loading/unloading inside the bathtub and away from street level noise receptors, if possible.
- The placement of most loading/unloading inside the bathtub and away from noise receptors located at street level.
- The designation of central areas for noisy activities, such as cutting steel or wood or use of noisy equipment such as impact wrenches. When feasible, use of pre-cut, pre-fabricated, or modular construction materials that minimize need for on-site fabrication or cutting methods.

Construction specifications will be developed for the project in coordination with the Lower Manhattan Construction Coordination Group and the Lower Manhattan Construction Command Center that will include the protocols required for site contractors. As per the Executive Order forming the Lower Manhattan Construction Command Center, this process will include consultation with and input from the construction community.

Comment 29: PANYNJ should strengthen the Environmental Performance Commitments to mitigate air pollution, noise and vibration during construction. (Todorovich)

Response: As described in Chapter 9, "Air Quality" and Chapter 10, "Noise and Vibration," PANYNJ has committed to additional measures beyond the Environmental Performance Commitments to avoid, minimize, or mitigate the potential construction-period impacts of the Preferred Alternative.

To reduce potential air quality emissions during construction: PANYNJ would implement mitigation as follows:

PANYNJ would implement the following mitigation measures to reduce project-generated emissions during the construction period. These measures include those previously identified as EPCs.

- Ultra Low Sulfur Diesel Fuel (ULSD): As described in the EPCs, PANYNJ would require that contractors use ULSD for all non-road vehicles that operate with diesel engines.
- Electrification: PANYNJ or its contractor would develop a plan, in consultation with Con Ed, as appropriate, to disperse grid power throughout the contraction zone for the Preferred Alternative. In its contract documents,

PANYNJ would require all contractors and subcontractors to use electrically powered equipment for air compressors, pumps, mixing, desanding and grout plants, welding machines, and any other diesel powered equipment that can be replaced with an electrically powered version. However, this does not apply to the east-west pedestrian concourse beneath Route 9A if the concourse is built by NYSDOT, since NYSDOT has not yet finalized what level of electrification would be possible for its projects. Given current conditions, it is expected that at lest 50 percent of the air compressors, pumps, mixing, desanding and grout plants, welding machines, and other diesel powered equipment that can be replaced with an electrically powered version would operate on electric power sources.

- Tailpipe Reduction Measures: In its contract documents, PANYNJ would require the use of Diesel Particle Filters (DPFs) or other measures with equivalent Particulate Matter (PM) removal efficiency for all nonroad diesel engines of 50 horsepower or greater wherever the implementation of such a device is feasible. However, there may be cases where DPFs would not be feasible for safety considerations, mechanical reasons, or where the technology would not function properly. In such cases, the constructor would submit a request for an exception for review and approval by PANYNJ prior to implementation, and in these cases, Diesel Oxidation Catalysts (DOCs) may be used. Only in cases where, for technical reasons, neither DPFs or DOCs can be used effectively, and where the operation cannot be performed by another engine or other means, would the use of diesel engines greater than 50 horsepower be allowed without tailpipe reduction measures, subject to the above-described approval process.

- Newer Engines: In its contract documents, PANYNJ would require the use of post-1995 fuel injection engines, which meet the Tier II engine emissions standards, as defined in Title 40, Part 89.112. Exceptions will be made only for specific engines that are not yet commercially available as Tier II, and where the task cannot be reasonably accomplished using alternative engines or means which do comply with these demands. In such cases, the contractor would submit a request for an exception for review and approval by PANYNJ prior to implementation.

- Diesel Emission Mitigation (DEM) Plan: PANYNJ would require contractors to prepare a DEM Plan that shall address the control of emissions from all engines and vehicles including those that are not equipped with emission control devices. As described in the EPCs, the DEM Plan would limit idling times on diesel powered engines to 3 minutes and would require that contractors locate diesel powered engines away from fresh air intakes.

- Dust Control Plan: As described in the EPCs, PANYNJ would require contractors to submit a Dust Control Plan. Among other things, the plan

would contain protocols and procedures for the spraying of dust piles, containment of fugitive dust, and appropriate adjustment measures to accommodate changes in meteorological conditions.

- Verification: The effectiveness of measures to reduce construction period emissions depends on compliance. To that end, verification procedures would be implemented through construction specifications and contract documents. PANYNJ would verify mitigation and would identify opportunities to expand its implementation as part of its ongoing oversight and auditing of the Project's construction. Furthermore, verification procedures would be implemented in accordance with decisions of the Lower Manhattan Construction Command Center, including procedures for reporting updates to the public.
- Other Emissions Reduction Technologies: PANYNJ is and will continue to investigate additional means (e.g., fuel emulsions) to reduce NOx (NO and NO2) emissions, but it is not yet known whether these measures would reduce the effectiveness of the above described mitigation. Therefore, specific means to further reduce NOx have not been identified in the mitigation plan for the Preferred Alternative at this time. If this investigation results in additional means to reduce NOx without jeopardizing the PM reducction measures and if other constraints such as technological availability are resolved, then PANYNJ would implement these additional mitigation techniques, as appropriate.

In addition to the noise mitigation measures identified in the above response to Comment 28, PANYNJ would require contractors to use specific equipment during phases of construction to reduce noise levels below the FTA impact criteria. During the permanent track, platform, and mezzanine construction contractors would be required to use Impact wrenches with noise emission level of 82 dBA at 50 ft^2 and mufflers on pavement breakers-+. During the construction of the east-west concourse, contractors would be required to place drill inside acoustical enclosure.

Per the stipulations of the executed Memorandum of Agreement for the Permanent WTC PATH Terminal, PANYNJ would prepare a Construction Protection Plan (CPP) for historic structures within 90 feet of the construction zone based on requirements in the "New York City Department of Buildings Technical Policy and Procedure Notice (PPN) #10/88" regarding procedures for the avoidance of damage to historic structures resulting from adjacent construction.

The CPP would describe in detail the construction procedures of the Preferred Alternative, as well as the construction procedures associated with other projects under construction in the vicinity of each of these historic properties. It would also provide for the inspecting and reporting of existing conditions at these properties, establish protection procedures, establish a monitoring program to

measure vertical and lateral movement and vibration, establish and monitor construction methods to limit vibration; and establish methods and materials to be used for any repairs. The plan shall also specify the implementation of special vibration protection measures to protect these historic properties from increased vibration levels associated with construction activities. The CPP would provide for a historical architect meeting the Secretary of Interior's Standards to supervise implementation of the CPP.

The CPP would empower the historical architect, in consultation with the Chief Engineer of PANYNJ to issue "stop work" orders to prevent any unanticipated damage to historic properties, and any recommencement of work shall only be permitted at such time that the Chief Engineer and historical architect have assurance that the appropriate modifications have been made to the construction technique to assure that no damage would occur to historic properties.

Comment 30: PANYNJ needs to ensure the implementation of the aggressive Environmental Performance Commitments established in the DEIS. (Carey)

Response: As described in Chapter 5, "Socioeconomic Conditions," Chapter 6, "Cultural Resources," Chapter 8, "Transportation," Chapter 9, "Air Quality," and Chapter 10, "Noise and Vibration," PANYNJ has committed to measures that would implement the EPCs. As appropriate, PANYNJ's implementation plans for the EPCs would be coordinated with the Lower Manhattan Construction Command Center.

Comment 31: As part its Environmental Performance Commitments, PANYNJ should include the Section 106 Consulting Parties in future discussions regarding potential impacts to historic resources. (Gardner)

Response: PANYNJ has committed to continued coordination with the Section 106 Consulting Parties per the stipulations of the executed MOA. The EPCs were intended primarily to protect access to cultural resources throughout the construction process. This will likely be coordinated through the LMCCC, which will provide for a public outreach officer to communicate with the local community and all other interested groups, including the Section 106 Consulting Parties.

LAND USE, NEIGHBORHOOD CHARACTER, AND PUBLIC POLICY

Comment 32: The DEIS should have examined how the occupation of a portion of the WTC site by the Terminal building limits the ability to develop the maximum commercial floor area on the WTC site. (Hemric)

Response: PANYNJ previously reviewed schemes for the development of a Permanent WTC PATH Terminal within the envelope of an office tower on the WTC site

or as part of a museum or cultural facility. However, consistent with the goals and objectives of this project, PANYNJ felt that the new terminal should have a visible, street-level presence to create a transportation gateway to Lower Manhattan. Thus, through a public planning process, PANYNJ and LMDC opted for a plan that would result in a separate PATH Terminal building and five office towers on the WTC site.

Comment 33: The DEIS did not examine how the Terminal building's lack of exterior street-level retail would negatively affect street life in the area (Hemric)

Response: Although the Terminal will have access to the street-level retail being planned as part of the WTC Memorial and Redevelopment Plan, street-level commercial space will not exist within the Terminal building itself. However, street-level retail will be located within the buildings immediately north and south of the Terminal. The area surrounding the Terminal building will be open space with amenities to serve the public. It is envisioned that the combination of street-level retail to the north and south of the Terminal and the plaza that will surround the Terminal building will create an active street life with functions that serve more than just retail.

Comment 34: The Permanent WTC PATH Terminal is primarily an underground infrastructure when complete and should not interfere with surface recreation such as park land, except at access or egress portals. For these locations, it would be appropriate to consider safety and resource loss mitigation during construction. (Taylor)

Response: The Preferred Alternative would not occupy public park land. The proposed headhouse adjacent to the Winter Garden would occupy private open space, and the location and construction of this headhouse is being coordinated with the property owner. The Project's Maintenance and Protection of Traffic (MPT) Plan will address pedestrian safety and access during the construction period.

Comment 35: The retail plan for the Terminal should complement the other retail components on the World Trade Center site and in the surrounding areas. Lower Manhattan should have a complete retail complex with shops and restaurants that serve the worker and residential populations Downtown, as well as commuters and the many visitors that will come to use the cultural and memorial spaces on the site and other attractions throughout the neighboring community. (Hensley)

Response: The Permanent WTC PATH Terminal, itself, will only include approximately 5,000 square feet of retail on its mezzanine level. This retail will cater to PATH users with services such as newsstands, sundries, and other convenience goods. The larger retail complex planned as part of the WTC Memorial and Redevelopment Plan will be closely coordinated with the Terminal's spaces to provide both above-grade and sub-grade access between the Terminal, its

concourses, office and cultural institutions on the WTC site, and the site's retail stores and restaurants.

SOCIOECONOMIC CONDITIONS

Comment 36: The DEIS should include an examination of "spontaneous", market-driven revitalization in Lower Manhattan and used that analysis to determine if an enlarged or enhanced PATH Terminal would be necessary. (Hemric)

Response: The DEIS applies an approach consistent with methodologies used for the environmental assessment of public and private projects in New York City. This approach develops a future population and employment projection based on a general background growth rate as well as any reasonably foreseeable residential and commercial development projects within the land use study area. The projections presented in the DEIS were based on land use projections prepared by the MTA on behalf of the Lower Manhattan Project Sponsors, and these projections have been used consistently in the environmental documents prepared for the Recovery Projects.

CULTURAL RESOURCES

Comment 37: FTA did not begin its Section 106 process in September 2003 concurrent with scoping for the Permanent WTC PATH Terminal project as stated in the DEIS. The first step in the Section 106 process is the identification of Section 106 Consulting Parties and the definition of an Area of Potential Effect. Section 106 Consulting Parties were not defined until January of 2004 and the APE was not defined until March 2004. (Gardner)

Response: FTA published its intent to prepare an EIS pursuant to the National Environmental Protection Act, Section 106 of the National Historic Preservation Act, and Section 4(f) of the U.S. Department of Transportation Act in its Notice of Intent, which was published in the *Federal Register* on September 26, 2003. The New York State Historic Preservation Officer (SHPO) was advised of the Notice of Intent and the scoping process for the DEIS at that time. Furthermore, public scoping meeting notices were sent to the project's mailing list, which included many of the individuals and organizations that would later serve as Section 106 consulting parties. FTA and PANYNJ received comments during scoping regarding potential effects to historic resources, which led to the formal solicitation of consulting parties pursuant to the preparation of a coordinated Determination of Eligibility, which began in December 2003.

Comment 38: The DEIS does not reference recent geoarchaeological research in Lower Manhattan that identifies a buried soil horizon. This soil horizon is believed to extend the length of Lower Manhattan and dates to approximately 2000 Before

Present. A determination of whether this soil horizon is present or has been intersection and removed by modern construction is essential to evaluating the archaeological sensitivity of the project outside the limits of the WTC bathtub. (Gardner)

Response: According to the geoarcheological report generated for the Worth Street site, which summarizes the studies conducted for the Foley Square project (Schuldenrein 2002), the buried soil horizon in question was found only in discontinuous locations within a geographically circumscribed portion of Lower Manhattan, bounded roughly by Broadway on the west, Worth Street on the north, and the Foley Square/Five Points area on the south and east. Furthermore, the report associates this buried soil horizon with specific geological formations (such as glacial kames, or low and steep-sided hills), found within the Worth Street study area vicinity, but not necessarily across all of lower Manhattan. Although the report claims that this soil horizon might be found throughout lower Manhattan, there is no evidence presented that confirms its location beyond the particular sites that were investigated. Last, it should be noted that although this buried soil horizon was documented at several locations, no precontact period archaeological resources were found in association with this soil in any of the samples. Thus, it appears that the possible presence of this soil horizon within the Project Site cannot necessarily be assumed, nor is there any evidence to date that confirms the presence of this soil horizon is directly related to the recovery of precontact archaeological resources.

The DEIS does specify potential adverse impacts to the Hudson River Bulkhead and yet underdetermined archaeologically sensitive areas on the eastern portion of the WTC site. As such, FTA and PANYNJ have developed measures to mitigate these potential impacts pursuant to Section 106 of the National Historic Preservation Act.

Comment 39: The DEIS fails to acknowledge that the physical remains of the World Trade Center, including the truncated box beam column that form the perimeter of the tower footprints are archaeological resources. Thus, studies presented in Appendix B are inadequate to make the assumption that the current potential for archaeological resources on the WTC site is the same as prior to September 11, 2001. (Gardner)

Response: The remaining remnants and structures on the WTC site were evaluated as historic resources under Section 106 of the National Historic Preservation Act since these resources are presently unearthed.

Comment 40: The DEIS fails to describe the possibility that remnants of the *Tyjger* may exist in the spaces between the east slurry wall of the WTC "bathtub" and the west wall of the IRT subway tunnel. (Gardner)

Response: According to PANYNJ drawings and a field visit, it appears that the slurry wall abuts the IRT subway wall. Based on documents referenced in PANYNJ"s 2003 Phase 1A reports, the slurry wall was constructed as a solid wall of concrete which replaced the soil once located there.

Comment 41: It cannot be certain that prior utility and subway construction have fully disturbed or removed archaeological resources beneath Church Street and Liberty Plaza. It is recommended that additional research be conducted to substantiate the DEIS finding regarding archaeological resources in the vicinity of Church Street and Liberty Plaza Park. (Suphin)

Response: The Preferred Alternative for the Permanent WTC PATH Terminal would not result in a subgrade concourse beneath Church Street to Liberty Plaza. Therefore, the project would not disturb any potential, remaining archaeological resources beneath the roadway or within the Plaza.

Comment 42: The analysis presented in the DEIS assumes that the Coordinated Determination of Eligibility (March 31, 2004) provides a proper basis for the evaluation of the project's potential effects on historic resources. The Coordinated Determination of Eligibility is faulty in many regards, including its failure to properly define the period of significance, its failure to acknowledge the significance of the site under more than one National Register eligibility criteria, and its improper application of the concepts of integrity. The FTA should request a formal determination from the Keeper of the National Register and that the Determination of Eligibility is revised appropriately. (Gardner)

Response: FTA does not plan on making such a referral. FTA believes that the Coordinated Determination of Eligibility provides a proper basis for the Section 106 review process. FTA and PANYNJ have provided additional information about the WTC site and the potential impacts of the Preferred Alternative through meetings and correspondence with the Section 106 consulting parties throughout the process to develop a Memorandum of Agreement. Therefore, the recommended mitigation measures were not limited by the Coordinated Determination of Eligibility. FTA and PANYNJ believe that the Memorandum of Agreement provides for appropriate measures and treatments with respect to the WTC site.

Comment 43: In discussing the setting of the WTC Site, the DEIS fails to distinguish between the Area of Potential Effect for historic remains and archaeological remains. A discussion of the setting associated with the World Trade Center ruins and remains should be included. Furthermore, the DEIS should include "setting" among the characteristics of the WTC Site that will be diminished. (Gardner et al)

Response: The Areas of Potential Effect for Historic and Archaeological resources are shown in Figure 6-1, and Chapter 6, "Cultural Resources" of the DEIS and this FEIS, and the corresponding text describes them separately.

With respect to the setting of the WTC site, the Draft Finding of Effects, which was presented as Appendix B of the DEIS concluded the following:

The project will introduce a new building and several small structures (such as vents and street access to concourses) into an APE that already contains a wide variety of historic and modern buildings ranging in height from one to 60 stories. Although the construction is new, the terminal, multiple accesses to the street level, and ventilation shafts functionally replace the same uses that existed prior to September 11, 2001. The proportions and architectural styles of the adjacent buildings vary greatly, reflecting the various periods in which they were designed and constructed. Historic masonry-clad buildings stand beside contemporary buildings constructed of glass, concrete, and metal in the APE north, east, and south of the project site; the entirety of Battery Park City on the west dates to the 1970s. The WTC itself initiated the introduction of modern (1960s) skyscrapers to the neighborhood. Redevelopment of the WTC Site, which will be underway independently of the Permanent WTC PATH Terminal, will again bring skyscrapers to the site of the WTC, including the Freedom Tower at the northwest quadrant of the WTC Site, and several somewhat shorter but still prominent office towers on the eastern portion of the site. The proposed Permanent WTC PATH Terminal will also be of contemporary design but of smaller scale than the other buildings proposed for the WTC Site under the Redevelopment Plan. Each of the two vent structures currently proposed to be located in the Route 9A median, west of the WTC Site, would be of long and slender massing and would stand approximately 40 feet tall. It is anticipated that the structures would be clad in reflective material, in keeping with modern material used on buildings in the immediate area.

The urban environment forming the setting of the WTC Site will continue to possess its distinguishing variety. Therefore, the introduction of the new Permanent WTC PATH Terminal and associated vent and access structures will not diminish the integrity of the WTC Site's setting.

Comment 44: The DEIS consistently employs words such as "could" and "may" when discussing effects to specific historically significant elements of the WTC site. Such words suggest uncertainty as to the exactly if and/or how various elements will be affected. Not only is this because of the insufficiently detailed description of the project but also because a complete inventory (with maps) of the historically significant elements at the WTC site was never prepared as part of the Coordinated Determination of Eligibility. A complete inventory of both site features and off-site artifacts should be conducted. In the absence of a

complete inventory, any assessments of effects or proposals for mitigation are premature. (Gardner, Gardner et al)

Response: The Permanent WTC PATH Terminal is currently in its design stage. It is known that the project will impact the approximately 16-acre, National Register-eligible WTC site, but the extent of this impact to specific remaining remnants and structures on the WTC site was uncertain at the time of the publication of the DEIS. Subsequent to publication of the DEIS, FTA and PANYNJ held four meetings with the project's Section 106 consulting parties. At these meetings, FTA and PANYNJ provided additional information regarding the Terminal's design and its potential impacts on remaining remnants and structures within the WTC site. Where specific effects are known, the findings presented in the FEIS have been updated, and mitigation measures have been developed. In cases where effects remain uncertain, the executed Memorandum of Agreement provide for stipulations to address these potential impacts should they occur.

PANYNJ is currently conducting HABS/HAIR Level II documentation of the WTC site pursuant to the stipulations of the executed Memorandum of Agreement. PANYNJ has also conducted a detailed inventory, including a photographic log, of all artifacts located within Hanger 17 of John F. Kennedy Airport.

Comment 45: FTA and PANYNJ should make attempts to preserve and/or incorporate remaining remnants on the WTC site into the project's design. FTA and PANYNJ should immediately prepare specific plans to incorporate the viewing and access of historic elements into the everyday experience of the Permanent WTC PATH Terminal. In cases, where adverse impacts to certain elements are absolutely unavoidable, the FTA and PANYNJ should immediately share plans with the Section 106 Consulting Parties for the mitigation of these impacts. Specifically the elements that should be incorporated into the design include: box beam column remnants marking the tower perimeter; northwest remnant sub-grade structures; passageway to E-train; steel beams in cross form; plaza; and subway entrance to Vesey Street. (Lustbader, Todorovich, Yaro; Sanchis III et al 1, Sanchis III et al 2)

Response: Subsequent to publication of the DEIS, FTA and PANYNJ held four meetings with the project's Section 106 consulting parties. At these meetings, FTA and PANYNJ provided additional information regarding the Terminal's design and its potential impacts on remaining remnants and structures within the WTC site. Based on consulting party comments, FTA and PANYNJ developed alternatives for components of the Terminal to minimize or avoid adverse effects, and alternatives were selected based on consulting party input. Subsequent to this process, FTA and PANYNJ developed a Memorandum of Agreement that contains the design measures developed through the Section 106 consultation

process. The project's consulting parties were given multiple opportunities to comment on a draft Memorandum of Agreement prior to its execution. Thus, FTA and PANYNJ believe that the Section 106 consultation process has provided a sufficient level of investigation to avoid, minimize, or mitigate the Preferred Alternative's adverse impact on the 16-acre WTC site.

Comment 46: PANYNJ should respect the wishes of many family members of the victims of the terrorist attacks and should not construct atop the tower footprints. (Lachman)

Response: Through its Section 106 review process, the FTA and PANYNJ have been working closely with Section 106 Consulting Parties, which include groups representing the victims' families. This process has resulted in a Memorandum of Agreement that specifies measures to minimize and mitigate the adverse effects of the Terminal to the tower footprints.

Comment 47: The discussion of the tower perimeter column bases implies that it is the column bases that constitute the footprints of the Twin Towers. The DEIS never discusses the footprints of the Twin Towers as a holistic entity. The tower perimeter column bases are discussed separately from other features located within the footprints proper. A discussion of how the footprints in their entirety will be affected is essential to properly evaluate the effects to them and to properly evaluate the project with respect to Section 4(f) of the U.S. Department of Transportation Act. (Gardner, Gardner et al, Kornfeld)

Response: The Memorandum of Agreement acknowledges that the column bases delineate the north and south tower footprints. The Memorandum of Agreement also stipulates measures to avoid, minimize, or mitigate the Preferred Alternative's effects to the columns bases and the spaces that they define.

Comment 48: The DEIS implies that physical disturbance of the truncated box beam columns is the only way they will be affected. The statement that the project would impact "some" of the columns is incorrect. They will all be affected in that their associated setting will be altered. The statement that some of the column bases while being made inaccessible could remain in situ is not very meaningful. If they become inaccessible they will be adversely affected. (Gardner et al)

Response: The DEIS describes the direct alteration or removal of remaining structures and elements on the WTC site resulting from the construction and operation of the Permanent WTC PATH Terminal. As described in Chapter 6, "Cultural Resources," collectively, the alteration or removal of these remaining structures and remnants would alter the integrity of feeling of the WTC site, which is noted as an adverse impact.

With regard to setting, the project will introduce a new building and several small structures (such as vents and street access to concourses) into an APE that already contains a wide variety of historic and modern buildings ranging in height from one to 60 stories. Although the construction is new, the terminal, multiple accesses to the street level, and ventilation shafts functionally replace the same uses that existed prior to September 11, 2001. The proportions and architectural styles of the adjacent buildings vary greatly, reflecting the various periods in which they were designed and constructed. Historic masonry-clad buildings stand beside contemporary buildings constructed of glass, concrete, and metal in the APE north, east, and south of the project site; the entirety of Battery Park City on the west dates to the 1970s. The WTC itself initiated the introduction of modern (1960s) skyscrapers to the neighborhood. Redevelopment of the WTC Site, which will be underway independently of the Permanent WTC PATH Terminal, will again bring skyscrapers to the site of the WTC, including the Freedom Tower at the northwest quadrant of the WTC Site, and several somewhat shorter but still prominent office towers on the eastern portion of the site. The proposed Permanent WTC PATH Terminal will also be of contemporary design but of smaller scale than the other buildings proposed for the WTC Site under the Redevelopment Plan. Each of the two vent structures currently proposed to be located in the Route 9A median, west of the WTC Site, would be of long and slender massing and would stand approximately 40 feet tall. It is anticipated that the structures would be clad in reflective material, in keeping with modern material used on buildings in the immediate area.

Comment 49: How many box beam column bases will be "temporarily" covered during construction? For how long? How will they be affected and protected during construction? (Gardner et al)

Response: All of the box beam column bases that are not currently covered and that would remain on-site would be covered during the construction period for their protection. Per the stipulations of the Project's Memorandum of Agreement, PANYNJ will develop a Resource Protection Plan for the WTC site that will include measures to protect the box beam column bases during the construction period.

Comment 50: There is an urgent need to remove the few inches of dirt that obstruct the remains of the footprints so that they can be properly inventoried, identified, documented, and photographed. (Gardner et al)

Response: PANYNJ removed the few inches of dirt that obstruct the remains and have documented and photographed remaining features. Upon completion, this documentation will be circulated to the project's Section 106 Consulting Parties.

Comment 51: The DEIS states that "obscuring the features from public view would not necessarily diminish the site's integrity of feeling." The present setting includes full access to and visibility of the north tower footprint and much of the south tower footprint. The ability to see and possibly touch the remains of the WTC is integral to the feeling associated with the site. The post-Terminal construction site will look very different from today. It will evoke less of a feeling of the effects of the events of September 11, 2001. The covering of portions of the footprints by tracks and portions of air space above the footprints by the Terminal structure will alter the setting of the WTC site. (Gardner et al, Sanchis III et al 1, Sanchis III et al 2)

Response: Refer to the response to Comment 48 above.

Comment 52: The statement that "all of these Tower perimeter columns were removed" is incorrect and contradicts the following phrase which states that the bases of the columns remain. (Gardner et al)

Response: The statement in Chapter 6, "Cultural Resources" of this FEIS was revised for clarification as follows: "During the post-September 11, 2001 emergency recovery operations conducted by the City of New York, all of these Tower perimeter columns were truncated such that only the bases remain."

Comment 53: The fact that construction of various proposed infrastructure elements will not physically destroy any of the truncated box beam columns is not meaningful in itself. The DEIS notes that proposed infrastructure "may somewhat impact visibility and accessibility." Exactly what does this mean? Much more specific information is needed. (Gardner et al)

Response: There would be various site infrastructure elements supporting the Preferred Alternative within the PATH right-of-way. The Preferred Alternative may also include utility lines that cross the footprints of the former North and South Towers at an elevation above the existing floor of the WTC site (Elevation 242 or 58 feet below Sea Level). Under current plans, these utilities would be at Elevation 264 (36 feet below Sea Level). These utility lines would serve the joint infrastructure needs of both the Permanent WTC PATH Terminal and the WTC Memorial and Redevelopment Plan.

The Preferred Alternative platforms and supporting infrastructure may permanently obscure 5 to 7 of the North Tower perimeter column bases and up to 3 of the South Tower perimeter column bases that currently exist outside of the PATH right-of-way. Given safety considerations, these column bases would be inaccessible to the general public. However, as described in the executed Memorandum of Agreement, PANYNJ will provide for architectural treatments within the Terminal such that a minimum of 5 to a maximum of 7 column bases of the east column line of the North Tower would be visible from Platform D.

Comment 54: Exactly what alterations that would be "additive in nature" are being referred to? While they may not "result in diminution of the physical characteristics of features," they still may adversely affect these features in other ways. (Gardner et al)

Response: As described in Chapter 2, "Project Alternatives," a fourth platform, an east-west concourse, a north-south concourse, and an above-ground Terminal Building will be constructed within the WTC site beyond the limits of the temporary WTC PATH station. The analysis indicates that such "additive" alterations will change the existing environment within the site through the introduction of new elements, thereby diminishing the Site's integrity.

Comment 55: The need for an additional track should be qualified and its adverse effects on the historic site should be considered. (Kornfeld)

Response: As described in Appendix C-2 of this FEIS, PATH requires a five-track operation at the WTC Terminal to support daily operations on the Newark-WTC and Hoboken-WTC routes, to allow for overnight train storage, or to provide for failure management.

In order to maintain reliable operations for its customers, PATH must plan for system failures that result in service disruptions. Disruptions can occur for a number of operational and maintenance reasons such as police actions, medical emergencies, equipment failures, routine maintenance and construction; and special operations. In the event of car equipment failure, PATH must have facilities to layover trains if they become fully disabled. Because PATH's WTC facility is a terminal station, trains dwell at the station in order to maintain the scheduled headways. Thus, each of the Hoboken-WTC and Newark-WTC routes require two active tracks such that an incoming train can arrive before an outgoing train departs. However, if a train becomes disabled, an additional track is needed to serve the next or multiple incoming trains.

Because of system-wide limitations and to allow for a more efficient operation during the start of early morning service, PATH uses four of the five tracks at the WTC for overnight storage of 6 Hoboken-WTC trains. The Terminal's fifth track is retained for revenue service on the Newark-WTC Line. Beginning at approximately 5:40 AM each morning, PATH begins revenue service on the Hoboken-WTC Line by bringing the train stored at Journal Square into the WTC Terminal. Trains are then moved from storage at the WTC to revenue service every 10 minutes following the departure of the first train until all 7 consists are operational. This plan allows PATH to more efficiently manage its labor hours and decreases the time that Hoboken-WTC trains are in non-revenue operation. During winter months, the overnight storage of trains at the WTC facility allows PATH to establish AM peak Hoboken-WTC service without first removing snow or ice from the trains and tracks.

During construction of the Preferred Alternative, the existing Tracks 1 through 5 would be taken out of service one at a time to allow for permanent track and platform installation. Thus, a temporary Track 6 is needed during construction to maintain PATH's minimum operating requirements.

As stipulated in the executed Memorandum of Agreement, the temporary PATH track (in addition to the existing 5 tracks) and associated ballast that would be installed on a temporary basis during construction of the Project tracks and platforms would be removed upon completion of the permanent tracks and platforms to re-expose the North Tower perimeter column remnants and portions of the North Tower footprints that may be covered by the temporary track and ballast.

Comment 56: The Memorandum of Agreement should incorporate a specific commitment to loop utilities and other infrastructure outside the tower footprint. (Sanchis III et al 2)

Response: As described in Chapter 6, "Cultural Resources" of this FEIS, the Preferred Alternative may also include utility lines that cross the footprints of the former North and South Towers at an elevation above the existing floor of the WTC site (Elevation 242 or 58 feet below Sea Level). Under current plans, these utilities would be at Elevation 264 (36 feet below Sea Level). These utility lines would serve the joint infrastructure needs of both the Permanent WTC PATH Terminal and the WTC Memorial and Redevelopment Plan..

Comment 57: The DEIS states that "the tower perimeter column bases would be preserved in place to the maximum extent possible." It is unclear what the phrase "to the maximum extent possible" means. FTA and PANYNJ should acknowledge their commitment to preserve 97 percent of the north tower footprint and 50 percent of the south tower footprint. (Gardner)

Response: As described in the executed MOA, the total extent of the North Tower footprint at elevation 242 (58 feet below Sea Level) to be permanently occupied by any portion of the Project would be approximately 1,600 square feet and would not exceed 4 percent of the North Tower footprint area. The total extent of the South Tower footprint at elevation 242 (58 feet below Sea Level) to be permanently occupied by any portion of the Project would be approximately 23,615 square feet (21,615 currently occupied by the temporary WTC PATH station plus 2,000 additional square feet for the Permanent WTC PATH Terminal) and would not exceed a total of 53 percent of the South Tower footprint area..

Comment 58: The discussion of how the remains of the Hudson and Manhattan tubes and terminals will be affected needs to be much more detailed. (Gardner et al)

Response: As stated in Chapter 2, "Project Alternatives," of this FEIS, construction of the Terminal may also require the demolition and excavation of remaining structures within the eastern portion of the WTC site between MTA/NYCT's 1 and 9 line and Church Street, which includes all portions of the former H&M Terminal. This work would also support the future development of the site by others. Per the stipulations of the executed Memorandum of Agreement, PANYNJ would fully document the remains of the former H&M Terminal to HABS/HAER Level II Standards prior to demolition.

Comment 59: The DEIS states that the remaining portions of the former Hudson & Manhattan (H&M) Terminal and the cast-iron tubes leading from the station do not meet criteria for listing on the National Register due to a loss of historic integrity. This statement is inconsistent with other findings, specifically the Coordinated Determination of Eligibility and the LMDC's Programmatic Agreement. (Gardner)

Response: Prior to the Coordinated Determination of Eligibility for the WTC site, SHPO determined that the remaining portions of the former H&M Terminal and the cast-iron tubes leading from the station do not meet the criteria for listing on the National Register as an entity onto itself due to a loss of historic integrity (letter dated October 16, 2003). However, given its location within the 16-acre WTC site, the former H&M Terminal was listed as a remaining remnant and structure in the Coordinated Determination of Eligibility. As such, the Preferred Alternative's effects on the H&M Terminal remnants were reviewed pursuant to Section 106 of the National Historic Preservation Act.

Comment 60: All of the slurry walls should be considered equally significant, and the DEIS must identify whose undertaking is associated with effects to the west slurry wall. Furthermore, FTA must determine whether or not bathtub wall reinforcement is or is not part of their project. If it is not, then presumably it is part of LMDC's project. Yet, the LMDC never discussed it in their Final Generic Environmental Impact Statement or Record of Decision for the WTC Memorial and Redevelopment Plan. (Gardner et al)

Response: As described in Chapter 2, "Project Alternatives," of this FEIS, the Preferred Alternative includes funds for the reinforcement of the basement ("slurry") walls, which form the "bathtub" within the WTC site. This work is necessary to ensure the structural integrity of the walls and to support future redevelopment of the WTC site, including the Permanent WTC PATH Terminal. As part of the Permanent WTC PATH Terminal's construction, PANYNJ could reinforce the entire west bathtub wall except for portions that would remain visible as part of the WTC Memorial. PANYNJ would also reinforce portions of the east bathtub wall abutting NYCT's 1 and 9 line that were not previously reinforced. If other development on the WTC site does not move forward according to current

schedules or plans, it may also be necessary to reinforce portions of the north bathtub wall east of Freedom Tower and portions of the south bathtub wall above the existing PATH substation. It is currently estimated that approximately 30 percent of the required slurry wall repairs would be undertaken as part of the Preferred Alternative.

Comment 61: The removal of the recovery and reconstruction ramp, although necessary and unavoidable, should be acknowledged as an adverse effect. Preservation plans for the ramp should be considered. (Gardner et al)

Response: The support foundation for the ramp would be relocated to allow for construction of a temporary track. The ramp would remain during early construction of the Preferred Alternative and would then be removed. Pursuant to the executed Memorandum of Agreement, the ramp would be documented to HABS/HAER Level II Standards prior to its removal.

Comment 62: The inclusion of a discussion of the "Northwest Remnant Subgrade Structures" as part of the project would seem to contradict numerous statements by PANYNJ that demolition of these structures is not part of the PATH project. (Gardner et al)

Response: Since publication of the DEIS, PANYNJ and the LMDC have pursued the removal of the Northwest Remnant Subgrade Structures under an independent action from the Permanent WTC PATH Terminal project. Therefore, this FEIS considers the Northwest Remnant Subgrade Structures as part of the Future Common to All Alternatives for the Permanent WTC PATH Terminal.

Comment 63: PANYNJ should consult with museum curators and investigate the possibility of salvaging more than three elements from the northwest remnant subgrade structures. Additional elements, along with the recently photographed Tito Dupret images, could provide for a more effective interpretation of the World Trade Center site. (Lustbader, Sanchis III et al 1, Sanchis III et al 2)

Response: Since publication of the DEIS, PANYNJ and the LMDC have pursued the removal of the Northwest Remnant Subgrade Structures under an independent action from the Permanent WTC PATH Terminal project. Thus mitigation measures pursuant to its removal are not part of this project.

Comment 64: The DEIS states that the entrance to the E train would be reconfigured and that certain elements associated with the existing E train passageway may be relocated. No description or drawings of the planned reconfiguration are provided, and no mention is made of which elements "may" be relocated. The passageway to the E train was recently restored and is one of the last surviving elements of the World Trade Center site. PANYNJ should conduct additional

analysis to incorporate the passageway into the Permanent WTC PATH Terminal's design. (Gardner et al, Lustbader; Love, Sanchis III et al 1, Sanchis III et al 2)

Response: As stipulated in the Project's MOA, the new pedestrian connection between the Permanent WTC PATH Terminal and the MTA/NYCT WTC E Subway Station would incorporate the existing E subway entrance, in its current location, in a manner that retains existing materials and features of this entrance, including, but not limited to, the handrails, the travertine flooring, the steps and doors separating the E train from the pedestrian connection, and overhead signage, to the extent possible and in accordance with current building codes and Americans with Disabilities Act requirements. The design would include, at a minimum, a plaque identifying the historic features of the E subway entrance. During construction of the new pedestrian connection between the Permanent WTC PATH Terminal and the E Subway Entrance, doors may need to be carefully removed and stored until they can be reinstalled within the new connection.

Comment 65: The steel beam in cross form should be moved temporarily within the World Trade Center site. If it needs to be moved off-site, proper public notification should be given, and it should be carefully preserved at JFK Hangar 17. (Lustbader, Sanchis III et al 1, Sanchis III et al 2)

Response: As stipulated in the executed MOA, PANYNJ would relocate the steel column and crossbeam mounted on a concrete pedestal and currently situated within the WTC site near Church Street in accordance with Stipulation VI of the MOA (see Appendix B). The object would remain in the custody and control of PANYNJ pending final disposition.

Comment 66: The steel beams in cross form should be removed from the site since it would be inappropriate as a permanent part of the site. The "steel cross" has an association with a particular religion on a site where people of many different religions perished. (Love)

Response: Refer to the response to Comment 65 above.

Comment 67: FTA and PANYNJ should not preserve everything that might be deemed a "ruin" by future generations. While most local residents are sensitive to victims' families and preservationist concerns, the primary focus has to be on the redevelopment of the site and economic revitalization of Lower Manhattan. (Gaull, Love)

Response: Through its Section 106 review process, the FTA and PANYNJ have been working closely with Section 106 Consulting Parties, which include groups representing the victims' families and local residents. This process has resulted

in a Memorandum of Agreement that specifies measures to avoid, minimize, and mitigate the Preferred Alternative's adverse effects to remaining remnants and structures on the WTC site.

Comment 68: The plaza and subway entrance at Vesey Street are the only surviving above ground elements of the World Trade Center site. The removal of these stairs is an avoidable adverse effect. The non-functionality and current instability of the stairs is given as a justification for their removal, which is unacceptable. Their non-functionality does not diminish their historical significance. FTA should identify the feasibility of stabilizing these remains and consider design modifications that would permit their preservation in place so they will not be adversely affected. (Gardner et al, Lustbader, Sanchis III et al 1)

Response: Subsequent to the publication of the DEIS, FTA and PANYNJ have determined that a proposed Permanent WTC PATH Terminal entrance in the location of the plaza and subway entrance to Vesey Street can be moved. As such, the Permanent WTC PATH Terminal would not impact the plaza and subway entrance to Vesey Street.

Comment 69: The decision to remove the structural remnants of the Vesey Street stairway is acceptable given its heavy damage and lack of permanent stability or functionality. (Love)

Response: As noted in the response to Comment 68, the Preferred Alternative would not alter the plaza and subway entrance to Vesey Street.

Comment 70: Avoidance of archaeological resources and data recovery are not the only forms of mitigation available for dealing with archaeological resources. (Gardner)

Response: The executed MOA includes the process to address the Preferred Alternative's impacts on the Hudson River Bulkhead and its potential impacts to as yet determined archaeological resources that may be located within the eastern potion of the WTC site. Because the Hudson River Bulkhead is also located within the APE for the Route 9A Project, PANYNJ would coordinate its treatment plan with NYSDOT. Similarly because the potential archaeological resources within the WTC site are also located within the APE for the WTC Memorial and Redevelopment Plan, PANYNJ would coordinate its treatment plan, if necessary, with LMDC.

In consultation with SHPO, and FHWA and NYSDOT, PANYNJ would develop and implement a plan to locate and identify intact portions of the Hudson River Bulkhead that would be affected by construction of the Permanent WTC PATH Terminal's east-west pedestrian connection. In the event that the intact portions of the Hudson River Bulkhead are identified, PANYNJ would, in consultation with the SHPO and NYSDOT, prepare a

treatment plan for those portions of the Hudson River Bulkhead to be affected by the Project. The plan would be submitted to SHPO and Section 106 consulting parties for their review and comment prior to implementation.

Prior to any Project-related subsurface disturbance at any of the locations that have been determined to be sensitive for historic archaeological resources, PANYNJ will, in consultation with the SHPO, and LMDC as appropriate, identify and evaluate the National Register eligibility of any archaeological resources at these locations in accordance with 36 CFR 800.4.

In the event that FTA, in consultation with SHPO, determines that National Register-eligible archaeological resources will be adversely affected by construction of the Preferred Alternative, PANYNJ would, in consultation with FTA, SHPO, and LMDC as appropriate, and the Section 106 consulting parties, develop and implement a Archaeological Resource Treatment Plan for the Project. The Archaeological Resource Treatment Plan and documentation will adhere to the standards established by the Secretary of the Interior's Standards and Guidelines for Archaeology (48 FR 44716), including the standards therein for professional qualifications. The plan will be submitted to SHPO and Section 106 consulting parties for their review and comment prior to approval.

Comment 71: The proposed photographic documentation of the entire WTC site should be done to HABS/HAER Level 1 Standards and the documentation plan should be subject to the review and approval of the National Park Service. (Gardner)

Response: Per the stipulations of the executed MOA, PANYNJ would document the WTC site and its historic features to Level II standards of the Historic American Buildings Survey/Historic American Engineering Record (HABS/HAER) prior to the removal or alteration of any historic features from the WTC site. This documentation will consist of large-format, black-and-white photography of the site and its historic features as they currently exist; large-format photographic reproduction of selected existing drawings of current conditions and of pre-September 11, 2001 conditions; and a written history and description of the site and its historic features using information previously generated for the Coordinated DOE for the WTC site as well as the Permanent WTC PATH Terminal's DEIS and FEIS. The completed documentation would be submitted to SHPO and HABS/HAER.

Comment 72: FTA should explore the desirability of inviting LMDC as a signatory to any Programmatic Agreement developed for the Permanent WTC PATH Terminal project given the high interrelationship with between this project and the World Trade Center Memorial and Redevelopment Plan. (Gardner)

Response: The LMDC signed the Permanent WTC PATH Terminal Memorandum of Agreement as a concurring party. (See Appendix B.)

Comment 73: The Hudson River Park Trust would like to be included in future discussions related to any impacts to the Hudson River Bulkhead and consistency with the existing Programmatic Agreement. (Blackman)

Response: As a consulting party to the Section 106 review process for the Permanent WTC PATH Terminal, the Hudson River Park Trust has been notified of all consulting party meetings including those that have outlined the project's Memorandum of Agreement. As a consulting party, the Hudson River Park Trust will be invited to review and comment on the Archaeological Resource Treatment Plan that will be developed for the project's potential impacts on the Hudson River Bulkhead.

Comment 74: The DEIS states that PANYNJ will coordinate with the other Lower Manhattan project sponsors "to minimize disruption in access to cultural and historic sites." The WTC site is considered a historic resource. If the LMDC, through its Programmatic Agreement, will control access to the tower footprints, then how can such coordination be possible? (Gardner)

Response: The above-referenced text refers to an Environmental Performance Commitment, which will be implemented during the construction period. The full text of this EPC states that the Lower Manhattan Recovery Project sponsors will "establish coordination among projects to avoid or minimize interruption in access to cultural and historic sites." The Environmental Performance Commitment pertains to off-site cultural resources including historic sites, community and religious institutions, museums, and other attractions. During the construction period, the WTC site will not be publicly accessible beyond public viewing areas that will be provided by PANYNJ and the LMDC. In the long-term, access will be controlled by LMDC and PANYNJ pursuant to the stipulations of their respective agreements that were developed in accordance with Section 106 of the National Historic Preservation Act.

URBAN DESIGN AND VISUAL RESOURCES

Comment 75: The DEIS assessment of the Terminal building's effects to visual resources is extremely cursory, one-sided, and based on highly dubious assumptions. The proposed Terminal building is an iconic, modernist structure that would have adverse effects on the visual character and heritage of Lower Manhattan. (Hemric)

Response: As described in Chapter 7, "Visual Resources," the Terminal building would be located on a site that contained modern structures prior to September 11, 2001 and modern structures will be constructed on the WTC site as part of the WTC Memorial and Redevelopment Plan. While Chapter 6, "Cultural Resources," identified historic structures in the vicinity of the project site, the area has a mix of both older and modern skyscrapers, including One Liberty Plaza and the

Hilton Millennium Hotel. Thus, a modern terminal building is in keeping with the urban context of this area. Furthermore, Church Street does not have a contiguous street wall in the vicinity of the World Trade Center site since newer structures are set back with exterior plazas. Thus, the shape and position of the Terminal will not adversely effect the urban design of the urea.

The density and patterns of development in New York City has resulted in adjacent iconic structures for some time. For example, Grand Central Terminal and the Chrysler Building are adjacent as is Rockefeller Center and Saint Patrick's Cathedral. The location of an "iconic" Terminal building in Lower Manhattan is in keeping with New York's history and patterns of development.

TRANSPORTATION

Comment 76: The DEIS should have noted how the plans for a Permanent WTC PATH Terminal would have a negative impact on passenger mobility and comfort when compared to the pre-September 11, 2001 PATH Terminal and concourse since the previous concourse was essentially at street level on all sides. (Hemric)

Response: While the Terminal's platforms and tracks would have a similar configuration to the pre-September 11, 2001, vertical and horizontal circulation would be much improved. Two concourses would provide for east-west and north-south access through the WTC site. These corridors would converge within the transportation hall, which would provide access to street-level, the Dey Street concourse of the Fulton Street Transit Center, and the Cortlandt Street (1 and 9), Cortlandt Street (N and R), and World Trade Center (E) subway stations. The concourse would also connect to elements of the WTC Memorial and Redevelopment Plan, including the memorial, cultural centers, offices, and retail on the WTC site. The east-west concourse would extend beneath Route 9A to a new entrance in front of the Wintergraden of the World Financial Center. This new Route 9A connection would allow for east-west travel between the WTC and World Financial Center without a major change in vertical grade, which was the case with the former north bridge of the WTC. The linear design of the concourses would provide for visual access to destinations and wayfinding signage would be provided throughout the complex. The proposed design of the concourses would provide for easier and more direct connections to transit stations and uses on and off the WTC site than was provided prior to September 11, 2001.

Comment 77: The DEIS should examine how the transformation of Lower Manhattan to a more well-rounded, 24-hour district might actually lessen the need for peak hour transit service. (Hemric)

Response: By 2025, employment in Lower Manhattan is projected to total nearly 422,000, which will be less than 1 percent fewer employees than existed prior to September 11, 2001. Although the residential population of Lower Manhattan

will increase by a much greater proportion than its commuter population, there will continue to be a substantial number of jobs in this area. Furthermore, prior to September 11, 2001, new and expanded office development in Jersey City, Newark, and Hoboken result in a rapidly increasing trend toward reverse-commuting by PATH. Currently, several office projects are planned in these areas that will likely result in more reverse-commuters in coming years. Thus, commuters between New Jersey and Lower Manhattan and those between Lower Manhattan and New Jersey will continue to constitute a substantial number of peak hour trips, and it is not anticipated that demand for peak hour transit service will lessen as compared to the pre-September 11, 2001 volumes.

Comment 78: The proposed connections between the Cortlandt Street (R and W) station and the World Trade Center (E) station should be integrated into the design of the Permanent WTC PATH Terminal as should the western end of the Dey Street passageway and the eventual connection to the Cortlandt Street (1 and 9) station. These connections should be designed to allow for fare-free transfers should MTA/NYCT subways and PATH adopt an integrated fare structure in the future. (Lachman)

Response: PANYNJ is coordinating with MTA to provide for a seamless connection between the Permanent WTC PATH Terminal and the Fulton Street Transit Center's Dey Street Concourse, the Cortlandt Street Station (1 and 9), the Cortlandt Street Station (R and W); and the World Trade Center Station (E). While these connections will allow for transfers between PATH and NYCT subways, they will also provide subgrade access between future uses on the WTC site. Therefore, these connections are not being planned as fare-free transfers. However, PANYNJ and MTA continue to work toward an integrated fare system that would allow for transfers between PATH and NYCT using a single fare-card. This system would be implemented for the transit connections within the WTC Transportation Hub when it becomes available.

Comment 79: The sound system for announcements at the WTC facility is absolutely terrible and messages are difficult to understand. (Gorsky)

Response: The Preferred Alternative would include a modern public address system to provide for announcements can be heard by commuters throughout the complex.

Comment 80: Before considering the design of the various subway stations involved, PANYNJ should consider methods of barrier-free fare collection. (Adler)

Response: As described in Chapter 8, Section A, "PATH," PANYNJ and MTA/NYCT are currently coordinating to develop an integrated fare collection system. However, the enhancement of fare collection for subways is a separate undertaking from the Permanent WTC PATH Terminal.

Comment 81: The PANYNJ should continue its work with the LMDC, the City, and the State to bring direct, one-seat access from Long Island and John F. Kennedy Airport to Lower Manhattan. These transportation improvements are critical to maintaining and enhancing Downtown's role as a central business district and a thriving part of the region's economy. (Hensley)

Response: PANYNJ in corporation with LMDC, MTA, and the New York City Economic Development Corporation are currently studying alternatives for a direct, rail connection between John F. Kennedy Airport and Lower Manhattan. However, this undertaking is independent from the Permanent WTC PATH Terminal.

Comment 82: The Permanent WTC PATH Terminal and a direct, high-speed connection to Newark Liberty International Airport presents an opportunity for Lower Manhattan to compete more effectively for job growth and development in the New York City metropolitan area. (McArdle)

Response: As described in Chapter 8, Section A, "PATH," of the DEIS, PANYNJ is studying PATH expansion projects including an extension from Newark Penn Station to Newark Liberty International Airport. However, this project is independent from the Permanent WTC PATH Terminal. The Preferred Alternative would support the future expansion of PATH to Newark Liberty International Airport.

Comment 83: To encourage greater ridership (particularly on nights and weekends) and to lessen use of automobiles, PANYNJ and MTA should agree to a ticket arrangement that would allow the user to pay one price for a combined PATH/MTA ride and should also consider combined unlimited PATH/MTA tickets similar to MTA/NYCT's current unlimited monthly subway pass. (Pasternack)

Response: As described in Chapter 8, Section A, "PATH," PANYNJ, and MTA/NYCT are currently coordinating to develop an integrated fare collection system. Presently, MTA pay-per-ride MetroCards are accepted at the temporary WTC PATH station and similar integration will be implemented at other PATH stations in the near future. In the long-term, the agencies hope to develop systems that allow for compatibility of other types of fare cards. However, the enhancement of fare collection is a separate undertaking from the Permanent WTC PATH Terminal.

Comment 84: The E train at the World Trade Center Station should be linked to the R and W line at Cortland Street, about a 100-foot distance to carry more passengers to the south at Whitehall/Water streets or even further to Brooklyn. (O'Shea)

Response: MTA/NYCT is considering a sub-grade connection between the World Trade Center (E) and Cortlandt Street (R and W) stations as part of the Fulton Street

Transit Center. However, this undertaking is independent from the Permanent WTC PATH Terminal.

Comment 85: The DEIS does not provide a sufficient explanation or appropriate backup for the 2025 ridership estimates. It is impossible for the reviewer to evaluate the legitimacy of the methodology or assumptions used to arrive at these estimates. An accurate estimate is imperative to justify the expansion of the facility beyond its pre-September 11, 2001 and current temporary capacity. (Gardner)

Response: A ridership appendix is included as Appendix C-1 of this FEIS. The appendix incorporates modifications to the ridership forecasts made subsequent to publication of the DEIS. These modifications reflect current ridership trends at the temporary WTC PATH station as well as development proposals and other planning efforts in both Lower Manhattan and New Jersey that may result in changes to future PATH ridership. This appendix was circulated in draft form for review by the project's Section 106 consulting parties in August 2004.

Comment 86: The PANYNJ recently announced that it will procure 246 new PATH cars that will have three doors on each side, which will allow for faster loading and unloading of passengers. The DEIS does not consider the potential of these cars to increase capacity and the degree to which improved loading and unloading will improve platform operations at the Permanent WTC PATH Terminal. (Gardner)

Response: As described in Appendix C-2 of this FEIS, three-door cars will decrease the boarding/alighting times of trains by 50 percent, which will improve dwell times and could reduce the overall travel time on PATH routes. However, the new cars are not expected to improve the station clearance time for passengers since they would not directly affect platform area or vertical circulation elements. Furthermore, since the WTC Terminal is a terminal station, passenger circulation at this facility is not highly influenced by the dwell times of trains.

Comment 87: The discussion of probable impacts associated with the various design options for a Permanent WTC PATH Terminal must include an evaluation of how these alternatives will affect historic resources, especially the WTC site. (Gardner)

Response: Chapter 6, "Cultural Resources," details the impacts of the Preferred Alternative on historic resources, including the WTC site. Additional analysis is provided in the Section 4(f) Evaluation.

Comment 88: As a result of the WTC Memorial, there will be no access to the transportation center, for residents living west of West Street. Reaching the Terminal will be a major obstacle since no one will be able to cross the Memorial. Because

NYSDOT proposes a tunnel under West Street, the PATH Route 9A connection will be deep and will pose a great hardship for those who use it. (Gaull)

Response: As currently planned, street-level access to the Terminal for those west of Route 9A could be achieved via the Route 9A Connection adjacent to the World Financial Center. The entrance to this connection would have vertical circulation including escalators and elevators. The connection below Route 9A will provide for easier movement between the concourse and the PATH mezzanine level than existed prior to September 11, 2001. Alternatively, those accessing the Terminal from west of Route 9A could cross Route 9A at grade and enter the Terminal via Freedom Tower, Greenwich Street, or Liberty Street.

AIR QUALITY

Comment 89: Air quality monitoring should be conducted within the WTC bathtub where PATH riders are walking and standing. (Coangelo)

Response: The National Ambient Air Quality Standards (NAAQS) standards are based on 24-hour and annual averaging periods, but the potential exposure time of PATH patrons within the "bathtub" would be considerably shorter. Thus, monitoring would be ineffective since these sort-term exposures would not have a relative basis for comparison.

Comment 90: Air quality monitoring results should be posted on a Website on a daily basis for residents and workers to obtain. (Coangelo)

Response: The Lower Manhattan Project Sponsors are currently investigating verification procedures and protocols for the Lower Manhattan Recovery Projects. This process will involve input from the New York State Department of Environmental Conservation to determine best practices for necessary data collection and reporting. The resultant, coordinated verification plan, including reporting methods, would be administered through the Lower Manhattan Construction Coordination Group or the Lower Manhattan Construction Command Center.

Comment 91: The EIS identified construction-period exceedance in particulate matter (PM) 2.5, which is the highly respirable kind. Where you have exceedance in $PM_{2.5}$, you can also have exceedance in very ultra-fine particulates, which may be even more dangerous to human health. The DEIS proposes to reduce or mitigate harmful effects to the extent possible, but who will determine what is possible and according to what criteria. (Orkin)

Response: PANYNJ would implement the following mitigation measures to reduce project-generated emissions during the construction period. These measures include those previously identified as EPCs.

- Ultra Low Sulfur Diesel Fuel (ULSD): As described in the EPCs, PANYNJ would require that contractors use ULSD for all non-road vehicles that operate with diesel engines.

- Electrification: PANYNJ or its contractor would develop a plan, in consultation with Con Ed, as appropriate, to disperse grid power throughout the contraction zone for the Preferred Alternative. In its contract documents, PANYNJ would require all contractors and subcontractors to use electrically powered equipment for air compressors, pumps, mixing, desanding and grout plants, welding machines, and any other diesel powered equipment that can be replaced with an electrically powered version. However, this does not apply to the east-west pedestrian concourse beneath Route 9A if the concourse is built by NYSDOT, since NYSDOT has not yet finalized what level of electrification would be possible for its projects. Given current conditions, it is expected that at lest 50 percent of the air compressors, pumps, mixing, desanding and grout plants, welding machines, and other diesel powered equipment that can be replaced with an electrically powered version would operate on electric power sources.

- Tailpipe Reduction Measures: In its contract documents, PANYNJ would require the use of Diesel Particle Filters (DPFs) or other measures with equivalent Particulate Matter (PM) removal efficiency for all nonroad diesel engines of 50 horsepower or greater wherever the implementation of such a device is feasible. However, there may be cases where DPFs would not be feasible for safety considerations, mechanical reasons, or where the technology would not function properly. In such cases, the constructor would submit a request for an exception for review and approval by PANYNJ prior to implementation, and in these cases, Diesel Oxidation Catalysts (DOCs) may be used. Only in cases where, for technical reasons, neither DPFs or DOCs can be used effectively, and where the operation cannot be performed by another engine or other means, would the use of diesel engines greater than 50 horsepower be allowed without tailpipe reduction measures, subject to the above-described approval measures.

- Newer Engines: In its contract documents, PANYNJ would require the use of post-1995 fuel injection engines, which meet the Tier II engine emissions standards, as defined in Title 40, Part 89.112. Exceptions will be made only for specific engines that are not yet commercially available as Tier II, and where the task cannot be reasonably accomplished using alternative engines or means which do comply with these demands. In such cases, the contractor would submit a request for an exception for review and approval by PANYNJ prior to implementation.

- Diesel Emission Mitigation (DEM) Plan: PANYNJ would require contractors to prepare a DEM Plan that shall address the control of emissions from all engines and vehicles including those that are not

equipped with emission control devices. As described in the EPCs, the DEM Plan would limit idling times on diesel powered engines to 3 minutes and would require that contractors locate diesel powered engines away from fresh air intakes.

- Dust Control Plan: As described in the EPCs, PANYNJ would require contractors to submit a Dust Control Plan. Among other things, the plan would contain protocols and procedures for the spraying of dust piles, containment of fugitive dust, and appropriate adjustment measures to accommodate changes in meteorological conditions.
- Verification: The effectiveness of measures to reduce construction period emissions depends on compliance. To that end, verification procedures would be implemented through construction specifications and contract documents. PANYNJ would verify mitigation and would identify opportunities to expand its implementation as part of its ongoing oversight and auditing of the Project's construction. Furthermore, verification procedures would be implemented in accordance with decisions of the Lower Manhattan Construction Command Center, including procedures for reporting updates to the public.
- Other Emissions Reduction Technologies: PANYNJ is and will continue to investigate additional means (e.g., fuel emulsions) to reduce NOx (NO and NO2) emissions, but it is not yet known whether these measures would reduce the effectiveness of the above described mitigation. Therefore, specific means to further reduce NOx have not been identified in the mitigation plan for the Preferred Alternative at this time. If this investigation results in additional means to reduce NOx without jeopardizing the PM reducction measures and if other constraints such as technological availability are resolved, then PANYNJ would implement these additional mitigation techniques, as appropriate.

As described in Chapter 9, "Air Quality,' these measures would reduce the maximum $PM_{2.5}$ increments of the Preferred Alternative by approximately 66 percent, and neighborhood scale increments would be reduced by half to below the threshold level of 0.1 $\mu g/m^3$,

Comment 92: The FTA and PANYNJ should have an objective, third-party for air quality monitoring. Otherwise, it may be a conflict of interest. (Orkin)

Response: Verification procedures would be implemented through construction specifications and contract documents to ensure the use of ULSD, maintenance of reduction technologies, dust suppression programs, and the use of grid power. PANYNJ would verify mitigation and would identify opportunities to expand its implementation as part of its ongoing oversight and auditing of the Project's construction.

Furthermore, as noted in the response to Comment 90 above, the Lower Manhattan Project Sponsors are currently investigating verification procedures and protocols for the Lower Manhattan Recovery Projects. This process will involve input from the New York State Department of Environmental Conservation to determine best practices for necessary data collection and reporting. The resultant, coordinated verification plan would be administered through the Lower Manhattan Construction Coordination Group or the Lower Manhattan Construction Command Center.

Comment 93: If exceedances of $PM_{2.5}$ occur during construction, how will PANYNJ address them? (Orkin)

Response: As described in the Response to Comment 91 above, PANYNJ has committed to mitigation that would reduce PM emissions by 66 percent as compared to the analysis presented in the DEIS. As such, exceedance is predicted only for a very small area immediately adjacent to Route 9A. The occurrence of such high levels would depend on the coincidence of peak background levels above the 98th percentile together with peak construction activity and extreme metrological conditions. At a very conservative maximum, this could occur on up to six days of the peak construction year. Such an occurrence, although possible, is not likely, and it would be a temporary situation, limited to a small area. Furthermore, this exceedance would not be expected to occur outside the peak construction year since activity would be reduced. Construction activity will be monitored in this area to ensure that emissions from construction equipment and extreme meteorological conditions are prevented from occurring concurrently.

Comment 94: The FEIS should provide a breakdown of the on-road and off-road emissions. (Hargrove)

Response: Chapter 9, "Air Quality" of the FEIS includes a distribution of on-road and off-road emissions. Of the total predicted project-generated emissions, 50 to 61 percent of VOC, 77 to 91 percent of NOx, 40 to 61 percent of PM_{10} and 78 to 88 percent of $PM_{2.5}$ would be from on–site sources.

Comment 95: The FEIS should provide a more detailed discussion of the NO_2 emissions and the technical data to support the conclusion that the analysis of NO_2 emissions is conservatively high as well as which other measures can be implemented to further minimize the emissions of $PM_{2.5}$ (Hargrove)

Response: The discussion of NO_2 emissions and their modeling assumptions have been expanded in Chapter 9, "Air Quality" and Chapter 15, "Cumulative Effects" of this FEIS. Since publication of the Draft Environmental Impact Statement, PANYNJ has worked with the Metropolitan Transportation Authority to further expand the Environmental Performance Commitments pursuant to construction-

period emissions. As described in this FEIS, PANYNJ has committed to the use of ultra-low sulfur fuel for all non-road equipment, limitation of unnecessary idling time on diesel powered engines to 3 minutes, Tier II standards for all non-road equipment, tailpipe reduction technologies for non-road engines of 50HP or greater, and the use of grid power, wherever possible, for engines that can operate on electric power such as welders; pumps; air compressors; and slurry, desanding, and grout mixers. Furthermore, PANYNJ is investigating the use of fuel emulsions. As noted in Chapter 9, "Air Quality," these combined measures would result in a substantial reduction in NO_2 emissions.

Comment 96: The mitigation measures identified in the DEIS do not affect the emissions of NO_2. The FEIS should assess a scenario that includes all of the stated mitigation measures from the DEIS as well as other measures that will significantly reduce emissions of particulate matter as well as NO_2 and NOx, in general. (Hargrove)

Response: PANYNJ has committed to the use of Tier II engines and the electrification of the equipment, such as welders; pumps; air compressors; and slurry, desanding, and grout mixers, that can operate on electric power, wherever feasible. These measures will substantially reduce the emission of NO_2. Furthermore, PANYNJ is investigating the use of other means (e.g., fuel emulsions) to reduce NO and NO_2 emissions.

Comment 97: The FEIS should be as definitive as possible on opportunities to reduce the emissions of NO_2 as the DEIS was for $PM_{2.5}$ emissions. This should include a description of the equipment that would be electrified and the degree to which electrification would reduce NO_2 emissions. (Hargrove)

Response: Refer to the above response to Comment 96.

Comment 98: Given that the New York Metropolitan Region is a nonattainment area for ozone, a cumulative inventory of emissions of NOx and VOC, as precursors to ozone formation, would be appropriate. (Hargrove)

Response: No emissions are expected under the Preferred Alternative in either the opening or design years. A mesoscale analysis of both on-road and off-road construction equipment and vehicles was prepared for this FEIS to identify the project's incremental increase in Nitrogen Dioxide (NO_2) and Volatile Organic Compounds (VOCs) during its construction. As compared to the projected regional emissions inventory in the New York ozone SIP for the same years—the on–road portion of the emissions would be less than 0.007 percent and 0.002 percent of the SIP mobile source NOx and VOC emissions, respectively; the on-site portion of the emissions would be 0.06 percent and 0.004 percent of the non-road SIP NOx and VOC emissions or less (depending on the year), respectively. The proposed mitigation for construction emissions, aimed at

reducing impacts in the immediate vicinity of the construction sites would also reduce the total region-wide emissions related to the Preferred Alternative.

NOISE AND VIBRATION

Comment 99: It is absolutely necessary that FTA and PANYNJ prevent and mediate potential construction-period vibration impacts to historic structures near the WTC site. It is recommended that state-of-the-art monitoring and stringent vibration standards be implemented. (Lustbader, Morrow)

Response: The executed Memorandum of Agreement includes protocols to prepare a CPP for historic structures that may be affected by construction-period vibration. Furthermore, the Memorandum of Agreement stipulates that PANYNJ would prepare a Resource Protection Plan for construction of the Project. (Refer to Chapter 6, "Cultural Resources" and Chapter 10, "Noise and Vibration" for more details regarding the components of these plans.)

Comment 100: Noise monitoring should be undertaken during construction. (Coangelo)

Response: PANYNJ would verify its noise mitigation measures and would identify opportunities to expand its implementation as part of its ongoing oversight and auditing of the Project's construction. This would include on-site noise monitoring during construction. Furthermore, verification procedures would be implemented in accordance with decisions of the Lower Manhattan Construction Command Center, including procedures for reporting updates to the public.

INFRASTRUCTURE AND ENERGY

Comment 101: FTA, PANYNJ, and the other Lower Manhattan project sponsors should implement an achievable time frame for the completion of infrastructure construction related to these projects. (Ayer)

Response: Supporting infrastructure for the Preferred Alternative would be constructed in phases. Most major infrastructure work associated with the Terminal would be complete in 2009.

Comment 102: FTA and PANYNJ should avoid any permanent impairment of utility infrastructure along the Route 9A pathway. (Ayer)

Response: The Preferred Alternative's concourse would traverse Route 9A below existing utility conduits. If these utilities are not relocated by NYSDOT as part of the Route 9A Project, PANYNJ would stabilize utility conduits as necessary to ensure that they would not be impacted during or after the concourse's construction.

Comment 103: FTA and PANYNJ should avoid any unnecessary additional costs to carriers associated with any infrastructure relocation or construction, to the extent carriers may be responsible for such costs. This would include avoiding multiple relocations, identifying any new routes as quickly as possible, providing adequate notice to all affected utilities, enlisting cooperation from building owners, and minimizing any disruption of telecom services to businesses and residential consumers. (Ayer)

Response: The construction of the Preferred Alternative would involve limited utility relocation within the WTC site and potentially along the west side of Church Street. PANYNJ would assume the cost for any utility relocation required to construct the Preferred Alternative. PANYNJ would coordinate with utility carriers prior to any necessary relocation.

Comment 104: FTA and PANYNJ must treat all carriers with infrastructure in the project areas in a non-discriminatory manner. This would include (but not be limited to) extending to these carriers any benefits Verizon receives with regard to easements, access to facilities, and recovery of restoration costs resulting from reconstruction projects under the Partial Action Plan for Utility Restoration and Infrastructure Rebuilding. (Ayer)

Response: PANYNJ would assume the cost for any utility relocation required to construct the Preferred Alternative. Operators will be properly informed of necessary utility work throughout the construction of the Permanent WTC PATH Terminal.

Comment 105: The DEIS described, as a benefit, the energy savings generated by a glass pavilion with natural illumination. However, the DEIS should have also examined the energy demanded by a subgrade pedestrian concourse, including a connection below Route 9A since the pre-September 11, 2001 concourse was not below-grade and since the former North Bridge was naturally illuminated. (Hemric)

Response: The pre-September 11, 2001 concourse was mostly enclosed with only a few access points directly to the street. Thus, the concourse itself did not benefit from natural illumination in most areas. The design of the Permanent WTC PATH Terminal will incorporate natural light from street-level through to the platform-level, which will reduce the need for artificial illumination as compared to the pre-September 11, 2001 facility.

While a pedestrian bridge over Route 9A would require less illumination than would a subgrade concourse during daytime hours, a major reduction in energy demand would not be realized. A bridge would be subject to natural heating during summer months and natural cooling during winter months, whereas, a subgrade concourse would have less variation in temperature throughout the

year. Thus, a bridge would require more energy for climate-control than would a subgrade concourse.

Comment 106: Telecommunications service, including emergency services, to Lower Manhattan may be disrupted or degraded, unless: PANYNJ ensures that the proposed underground pedestrian concourse does not disrupt or prevent Verizon's use of Route 9A or Church Street as a utility pathway. The proposed underground concourse has the potential to permanently impair Verizon's use of the Route 9A utility pathway. (Bachmore)

Response: The Preferred Alternative would not result in the relocation of utilities under Route 9A. There may be limited utility relocation along the west side of Church Street, but alternative pathways would be provided.

Comment 107: Since the various alternatives for the Lower Manhattan recovery projects each require a different relocation plan, it is imperative that the alternatives be narrowed and that any decisions regarding the relocation of the utilities be made be final and permanent. (Bachmore)

Response: Construction of the Preferred Alternative may require limited utility relocation along the eastern portion of the WTC site at the proposed location of the Terminal's connection with FSTC's Dey Street Concourse. PANYNJ would coordinate this relocation with efforts being undertaken by LMDC and MTA/NYCT to minimize any disruption to local utility operators.

Comment 108: The EIS does not disclose the adverse effects such as timing delays, service disruptions, disruptions to vehicular and pedestrian traffic, inconvenience to Lower Manhattan community, and wasted cost, if the utility relocation measures proposed by Verizon are not implemented. (Bachmore)

Response: The Preferred Alternative would not result in the relocation of Verizon's utility pathways beneath Route 9A. There may be limited utility relocation along the west side of Church Street. If Verizon utilities would be relocated, PANYNJ would coordinate relocation plans with the utility operator prior to their implementation.

CONTAMINATED MATERIALS

Comment 109: I am concerned that the DEIS finding that little hazardous materials remain in the project site is based on EPA data. (Orkin)

Response: USEPA data was not used to substantiate the finding presented in the DEIS. PANYNJ and LMDC have conducted Phase I and Phase II hazardous materials testing throughout the WTC site. NYSDOT has also conducted testing along Route 9A, in the vicinity of the proposed east-west connection for the

Permanent WTC PATH Terminal. All of these tests were conducted by licensed consultants under contact with the respective project sponsors.

NATURAL AND WATER RESOURCES

Comment 110: The PANYNJ should contact the National Oceanographic and Atmospheric Administration/Fisheries for information on Essential Fish Habitats and Federally-listed species and the New York State Department of Environmental Conservation for information on State-listed species. (Stilwell)

Response: Federal and state oversight agencies were contacted during the scoping process for the Permanent WTC PATH Terminal and the resultant correspondence is shown in Appendix G, "Natural and Water Resources." The reinstatement of the river water cooling system at the WTC site would be undertaken by LMDC and PANYNJ as part of the WTC Memorial and Redevelopment Plan. LMDC prepared an Essential Fish Habitat (EFH) Assessment of the Lower Hudson River estuary as part of its Final Generic Environmental Impact Statement (April 2004). (As noted in Chapter 13, "Natural and Water Resources," the EFH is available at LMDC's website, www.renewnyc.com). Subsequently, PANYNJ has filed a renewal application for the river water cooling system with the New York State Department of Environmental Conservation under a separate undertaking.

Comment 111: Given the importance of the Lower Hudson River estuary for aquatic species resources, it is recommended that a closed cooling system or one of the dry-cool technologies be used in the Permanent WTC PATH Terminal. If river water cooling is used, best management practices should be implemented to avoid impacts associated with impingement/entrainment and thermal discharge. (Stilwell)

Response: The river water cooling system includes two intakes located on the eastern shore of the Hudson River near the World Financial Center. River water cooling was used prior to September 11, 2001 and would be reestablished as part of the current redevelopment of the WTC site. The New York State Department of Environmental Conservation is currently reviewing PANYNJ's application to renew their State Pollutant Discharge Elimination System (SPDES) permit for the river water cooling system. As part of this application, PANYNJ has prepared a Best Technologies Available (BTA) study that specifies measures to protect fish eggs and larve from entrainment and entrapment associated with the systems intake grates. These measures include: 1) Using 3 gallons per minute (gpm)/ton chillers; 2) Variable speed pumps; and 3) Modifying the intake structure with 2 millimeter (mm) wedgewire screens to reduce the approach velocity to 0.5 feet per second (fps) with a corresponding river water flow of 120,000 gallons per minute (gpm).

While some level of impact to aquatic organisms due to entrainment of fish eggs (and much smaller numbers of larvae) is unavoidable utilizing the selected design, overall aquatic impacts are materially reduced from pre-September 11, 2001 conditions. The proposed system would eliminate the potential for impingement and would reduce entrainment of yolk-sac and post-yolk sac ichthyoplankton from pre-September 11, 2001 levels by an estimated 93 percent and 97 percent respectively. In fact, virtually all (approximately 98 percent) of the entrained organisms are eggs, which are subject to high rates of natural mortality and fecundity. By excluding life stages of entrainable organisms with higher natural survival rates, the selected design minimizes the adverse environmental impact of the cooling water intake structures.

The river water cooling system would be closed-circuit such that water extracted from the Hudson River would not be mixed with potable water or stormwater as it travels through the system. Therefore, the system would not alter the composition of Hudson River water.

Regulations set forth at 6 NYCRR Part 704 establish water quality standards governing thermal discharges to the waters of the state that requires. They require that "all thermal discharges to the waters of the State shall assure the protection and propagation of a balanced indigenous population of shellfish, fish and wildlife in and on the body of water" [6 NYCRR §704.1(a)]. Part 704 also sets forth specific criteria for discharges that, if met, would assure compliance with the standard. The criteria for estuarine discharges include a maximum surface temperature of 90°F, a limit on the lateral extent of a 4°F temperature rise to two-thirds of the width of the receiving river, and a limit on the cross-sectional area with a 4°F temperature rise to one-half of the river cross section. Because of Hudson River hydrodynamics, the maximum surface temperature of 90°F is the critical criterion to be met.

The BTA study specifies that the maximum designed change in temperature (ΔT) of the proposed river water cooling system is 10°F. Therefore, cooling water flow discharges would not result in temperatures in excess of the 90°F criterion, since the maximum ambient surface water temperature is 80°F.

Comment 112: It is recommended that measures be implemented to avoid or reduce the likelihood of impacts to migratory birds. Examples of these measures that would be applicable to this project include 1) minimizing window lighting and using strobes on aerial towers/antenne for aircraft beacons and orientating reflective window surfaces by using etched glass or adhesive films. (Stillwell)

Response: As described in the FEIS, PANYNJ will incorporate architectural and landscaping features into the project's design that will reduce the potential for both daytime and nighttime bird strikes. The measures identified above have been included in the proposed mitigation plan.

COASTAL ZONE MANAGEMENT

Comment 113: The evaluation of the project's consistency with Policy 10 of New York City's Waterfront Revitalization Program is inaccurate. The DEIS should discuss the adverse impact of the project on the WTC site and the project's failure to "retain and preserve designated historic resources." (Gardner)

Response: The full Policy 10 of the New York City Waterfront Revitalization Program states that a project should "protect, preserve, and enhance resources significant to the historical, archaeological, and cultural legacy of the New York City coastal area." Furthermore, Policy 10.1 states that the project should "retain and preserve designated historic resources and enhance resources significant to the coastal culture of New York City." The WTC site was not been determined historically significant for its role in the "coastal culture of New York City." Therefore, the finding presented in the DEIS is considered appropriate as it pertains to the Local Waterfront Revitalization Program.

Comment 114: The statement that the project "would not have an adverse impact on coastal resources" is incorrect and inconsistent with the finding that historic properties would be adversely impacted by the project. (Gardner)

Response: Refer to the above response to Comment 113.

CUMULATIVE EFFECTS

Comment 115: It would be advisable to produce a composite drawing to help the public understand the complete vision for the area and to keep them informed on a daily basis during construction. (Carey)

Response: In an April 2003 speech to the Alliance for Downtown New York, Inc., Governor Pataki laid out the vision for the redevelopment of Lower Manhattan. The vision was the Libeskind plan for the WTC site, which resulted in the programming of spaces for the World Trade Center Memorial and Redevelopment Plan, the Fulton Street Transit Center, the Route 9A Project, and the Permanent WTC PATH Terminal. Subsequently, PANYNJ has been coordinating with NYSDOT, LMDC, and MTA/NYCT to program spaces as specific project plans evolve. These plans have been made available to the public through the news media, public exhibitions, and the internet.

In accordance with Governor Pataki's November 22, 2004 Executive Order, the Lower Manhattan Construction Command Center will communicate with residents, businesses, and the general public through a communications director working with each agency's communications and public outreach personnel; providing a central focus on issues critical to the local community and the

construction industry, by coordinating initiatives, public outreach, and information.

Comment 116: The DEIS fails to adequately account for the cumulative effects of other planned and on-going projects on the WTC site. Of special concern is the relationship between the Permanent WTC PATH Terminal and the WTC Memorial and Redevelopment Plan. The LMDC's Programmatic Agreement is legally bound to provide "reasonable and appropriate access" to the tower footprints, but FTA and PANYNJ are not signatories. The final design of the Permanent WTC PATH Terminal will be a major factor in determining the extent and quality of access to the footprints. Thus, actions taken by the FTA and PANYNJ under the Memorandum of Agreement to minimize disturbance to the tower footprints, enhance the amount and quality of access, and/or avoid or minimize "use" of the footprints may be rendered moot by actions taken by the LMDC pursuant to their Programmatic Agreement. (Gardner, Gardner et al, Sanchis III et al 1, Sanchis III et al 2)

Response: The executed Memorandum of Agreement provides for stipulations to address potential cumulative effects on the WTC site. As described in the Memorandum of Agreement, PANYNJ would request that all agencies constructing projects within the WTC site submit preliminary and pre-final documents to PANYNJ. PANYNJ and its designated historic preservation consultant would consult with SHPO and the Lower Manhattan Emergency Preservation Fund to asses whether there would be the potential for a cumulative adverse effect from the Permanent WTC PATH Terminal and other WTC site projects based on the preliminary and pre-final plans. If SHPO and PANYNJ, agree that Project plans or completed activities have resulted in or are likely to result in cumulative adverse effects on the WC site, then PANYNJ shall consider measures with respect to the Permanent WTC PATH Terminal to mitigate or minimize these effects, including technical or financial measures for its protection, stabilization, or repair and Project design modifications. PANYNJ would make its documentation of potential cumulative effects and accompanying mitigation plans available for review by the National Park Service, the Advisory Council on Historic Preservation, the Lower Manhattan project sponsors, and the Section 106 consulting parties. PANYNJ's plans to minimize or mitigate adverse cumulative effects would also consider the stipulations within the Programmatic Agreements for the WTC Memorial and Redevelopment Plan, the Route 9A Project, and the Fulton Street Transit Center.

Comment 117: FTA, the Federal Highway Administration, and the LMDC should request a formal determination of National Register eligibility for the WTC site from the Keeper of the National Register of Historic Places. The existing determination is a "lowest common denominator" document that is badly flawed by the

reluctance of at least one of the agency/authors to even acknowledge that the WTC site is historic in any way. (Gardner)

Response: See the above response to Comment 42.

Comment 118: The statement that LMDC identified no adverse effects with respect to the WTC site is incorrect. Although LMDC did not make such a determination, it was effectively superseded when they entered a Programmatic Agreement with the SHPO and the Advisory Council on Historic Preservation, the purpose of which was to address "adverse effects on historic properties." (Gardner)

Response: Chapter 15, "Cumulative Effects," of this FEIS reflects LMDC's determination as follows: "LMDC identified potential adverse effects with respect to the WTC site and prepared and executed Programmatic Agreements that will guide the design and construction of their project with respect to potential impacts."

Comment 119: FTA and PANYNJ have attempted to minimize encroachment over the perimeter column bases which outline the footprints of towers one and two of the World Trade Center, but the cumulative impact of additional construction activities could minimize access to these bases. The FTA and PANYNJ should adhere to the design and construction goals outlined in the DEIS. (Lustbader, Sanchis III et al 1, Sanchis III et al 2)

Response: The Memorandum of Agreement for the Permanent WTC PATH Terminal provides for specific measures to minimize the short- and long-term effects of the Terminal on the perimeter column bases. These commitments consider the provisions set forth in the Programmatic Agreement among LMDC, the Advisory Council on Historic Preservation, and SHPO for the WTC Memorial and Redevelopment Plan.

Comment 120: Chapter 6, "Cultural Resources" and Chapter 10, "Noise and Vibration" state that the construction protection plan will be based on the requirements laid out in the New York City Department of Buildings Technical Policy and Procedure Notice #10/88. The Notice deals with procedures for avoiding damage to adjacent structures resulting from adjacent construction of a single project. It does not include procedures, vibration standards, and monitoring programs for cumulative construction projects. (Sanchis III et al 2)

Response: Pursuant to the stipulations of the Project's executed Memorandum of Agreement, PANYNJ would coordinate its Construction Protection Plan for the Barclay-Vesey Building with LMDC. It would coordinate its construction Protection Plan for St. Paul's Chapel and Graveyard and the Former East River Savings Bank with MTA/NYCT and LMDC. PANYNJ's Construction Protection Plans for the Beard Building and 114-118 Liberty Street would be coordinated with LMDC.

Comment 121: It is recommended that the Terminal's construction be coordinated through a single entity charged with overseeing all of the Lower Manhattan construction to reduce the potential cumulative impacts on surrounding historic properties. (Lustbader, Sanchis III et al 2)

Response: On November 22, 2004, New York State Governor George E. Pataki signed an Executive Order creating the Lower Manhattan Construction Command Center. The Command Center will administer the construction of project's within Lower Manhattan that either 1) have a construction value of more than $25 million; 2) require governmental actions or permits or; 3) require work within in a City or State street or highway.

The Command Center will coordinate community information, construction logistics, utility coordination, environmental compliance and safety, and diversity and equal opportunities in employment. The Command Center will be managed by an Executive Director to be appointed by the Governor and the Mayor of the City of New York. The Mayor will also appoint a Director of City Operations to act as a liaison between the Command Center and City officials. An Executive Committee, to be chaired by the Executive Director, will be appointed to facilitate communications between the Command Center, the Lower Manhattan Project Sponsors, and other key city and state departments and agencies.

As stated in the Executive Order, the functions of the Command Center will be:

- "Coordinating the work of the participants in the rebuilding process and ensuring that the construction in Lower Manhattan proceeds as scheduled by mediating conflicts in schedules and street and site access between construction projects, agencies, and the Lower Manhattan Community;"
- "Coordinating protocols, contract requirements and activities outside of individual project limits through planning on a daily basis throughout construction for government agencies, developers, construction managers, general contractors, and contractors;"
- "Coordinating construction projects to minimize inconvenience for residents, workers, pedestrians, vehicles, and commuters;"
- "Ensuring that the Lower Manhattan area remains neat, clean and orderly throughout construction;"
- "Communicating with residents, businesses, and the general public through a communications director working with each agency's communications and public outreach personnel; providing a central focus on issues critical to the local community and the construction industry, by coordinating initiatives, public outreach, and information;" and
- "Utilizing technology to facilitate coordination of projects."

Furthermore, pursuant to the stipulations of the executed Memorandum of Agreement for the Permanent WTC PATH Terminal, PANYNJ is committed to

coordinating with the appropriate Lower Manhattan Project Sponsors for potential cumulative effects on the WTC site, the Hudson River Bulkhead, the Barclay-Vesey Building, St. Paul's Chapel and Graveyard, the Former East River Savings Bank, the Beard Building, and 114-118 Liberty Street.

COMMITMENT OF RESOURCES

Comment 122: The DEIS should identify that the project's use of the WTC site constitutes a permanent, irretrievable and irreversible commitment of a historic resource. (Gardner)

Response: Chapter 16, "Commitment of Resources" of the DEIS identified the short-term use of historic and archaeological resources during the construction period. This FEIS also notes the Project's long-term use of the WTC site, which is a National Register-eligible historic resource. The FEIS also references the Memorandum of Agreement and its stipulations to avoid, minimize, or mitigate both the short- and long-term use of historic resources.

DRAFT SECTION 4(F) EVALUATION

Comment 123: The Draft Section 4(f) Evaluation describes 4 (five if one counts a variation) avoidance alternatives. Three of these (no action, relocation of PATH projections, and locate terminal off-site) are clearly not serious alternatives. Real alternatives include the Location 1 alternative described in Chapter 2 and a variety of alternatives involving design variations to the latter must be discussed. All of these alternatives would result in a reduction in the "use" of the WTC site. (Gardner, Sanchis III et al 2)

Response: As noted in the Final Section 4(f) Evaluation, which is included in this FEIS, the U.S. Department of Interior has agreed that there are no reasonable and prudent alternatives to the use of the historic property, which is defined as the 16-acre WTC site, to meet the transportation purpose and need of the project. Therefore, FTA and PANYNJ have developed measures to minimize harm through the project's Section 106 consultation process.

Comment 124: The Draft Section 4(f) Evaluation should clearly state that the project "would" rather than "may" use historic properties. (Gardner)

Response: The findings presented in the Section 4(f) Evaluation reflect specific impacts to cultural resources where known and includes the stipulations of the Project's Memorandum of Agreement that minimize harm to these resource. For yet determined impacts, the Final Section 4(f) Evaluation describes the potential impact and appropriate measures to minimize harm should impacts occur.

Comment 125: The description of the project's effects on historic resources and potential mitigation are identical to text presented in Chapter 6, "Cultural Resources." The Section 4(f) Evaluation should incorporate comments made on Chapter 6. (Gardner)

Response: The Final Section 4(f) Evaluation is updated to reflect changes made to Chapter 6, "Cultural Resources," in response to public comments on the DEIS.

Comment 126: The Section 4(f) Evaluation identifies physical remnants from the site that were listed in the Coordinated Determination of Eligibility. However, the list is incomplete. Furthermore, this list should be expanded to compensate for deficiencies in the Coordinated Determination of Eligibility that resulted from the incorrect application of the integrity standard and the failure to include the area within the tower footprints. (Gardner)

Response: The list of effects presented in the Draft Section 4(f) Evaluation reflects the findings presented in the Draft Finding of Effects pursuant to Section 106 of the National Historic Preservation Act. The Project's Section 106 Consulting Parties were invited to comment on the Draft Finding of Effects and changes were made in the FEIS pursuant to these comments. The FEIS discloses the Preferred Alternative's effects on the WTC site, including the footprint areas of the former North and South Towers.

Comment 127: The Draft Section 4(f) Evaluation states that the No Action Alternative still has the potential to remove or alter contributing elements of the WTC site. However, this is the case only because it is assumed that the World Trade Center Memorial and Redevelopment Plan would result in the need for additional egress and access locations and ventilation structures. If FTA and PANYNJ are coordinating with the LMDC as claimed, then it should be possible to develop a "no action" alternative that would not require the "use" of the historically significant WTC site features and still accommodate a Memorial. (Gardner)

Response: The No Action Aclternative for the Permanent WTC PATH Terminal has been clarified, and this alternative would not physically alter or remove historic structures or remnants on the WTC site. However, other changes in the WTC site could potentially occur as a result of the No Action Alternative, but the impacts of these changes are speculative at this time.

Comment 128: Figure 4(f)-2 should be modified to clearly show that the tower footprints in their entirety, not just the perimeter box beam columns, are the contributing elements to the significance of the WTC site, and a second figure should be provided that shows remnant structures within the footprints should be included. (Gardner)

Response: Figure 4(f)-2 identifies some of the remaining remnants and structures listed in the Coordinated Determination of Eligibility. Other column remnants and infrastructure on the WTC site are identified in the Determination of Eligibility. Furthermore, the revised finding of effects in the Final Section 4(f) Evaluation discloses the Preferred Alternative's effects on the footprints.

Comment 129: Avoidance alternatives 4A and 4B are incorrectly labeled in Figure 4(f)-3. (Gardner)

Response: Figure 4(f)-3 of the Final Section 4(f) Evaluation reflects the correct labeling of Alternative 4A, "Church Street" and Alternative 4B, "Vesey Street."

APPENDIX B: DRAFT FINDING OF EFFECTS

The following comments were submitted by Section 106 Consulting Parties pursuant to the Draft Finding of Effects document that was included as part of the DEIS. The Draft Finding of Effects document was incorporated into analysis presented in Chapter 6, "Cultural Resources," Chapter 15, "Cumulative Effects," and the Draft Section 4(f) Evaluation of the DEIS. Therefore, many of the comments made on the Finding of Effects have been noted above under the appropriate technical chapter. The comments below, however, are specific to the document that appears in Appendix B of the DEIS. This document was not updated as part of the preparation of the FEIS; however, applicable text and graphics in Chapter 6, "Cultural Resources," and the Final Section 4(f) Evaluation reflect these comments, as appropriate.

Comment 130: The description of the undertaking is not detailed enough to permit an independent evaluation of how, and to what degree, the historic resources within the project's Area of Potential Effect will be affected. While the figures in the Draft Finding provide some information, it is not possible to relate how what is being proposed will affect individual resources that contribute to the significance of the WTC Site. Much more detailed descriptions are necessary. For example, in referring to the E-Train passageway, the Draft Finding only says that the station will be reconfigured and that certain elements may be relocated. No description or drawings of the planned reconfiguration are provided, and no mention is made of which elements "may" be relocated. The fact that the FTA and the PANYNJ cannot state with certainty which elements are proposed for relocation suggests that any finding of effect is premature. (Gardner et al, Gardner)

Response: The Permanent WTC PATH Terminal is currently in its design stage. It is known that the project will impact the approximately 16-acre, National Register-eligible WTC site, but the extent of this impact to specific remaining remnants and structures on the WTC site was uncertain at the time of the publication of the DEIS. Subsequent to publication of the DEIS, FTA and PANYNJ held four meetings with the project's Section 106 consulting parties. At these meetings, FTA and PANYNJ provided additional information regarding the Terminal's design and its potential impacts on remaining remnants

and structures within the WTC site. Where specific effects are known, the findings presented in the FEIS have been updated, and mitigation measures have been developed. In cases where effects remain uncertain, the executed Memorandum of Agreement provide for stipulations to address these potential impacts should they occur.

Comment 131: It is unclear where the ventilation which may be constructed "adjacent to Route 9A" would be located. A graphic showing the location would be helpful, as would a description of the ventilation structure. (Gardner et al)

Response: As reflected in Chapter 2, "Project Alternatives" of this FEIS, the ventilation structures would be located within the median of Route 9A atop Tunnels E and F of the PATH system.

Comment 132: There is no discussion of what mitigative measures the FTA is proposing to avoid or minimize adverse effects to the WTC Site. Mitigative measures that have been considered and discarded, if any, should be identified. (Gardner et al)

Response: A discussion of preliminary mitigation measures was provided in Chapter 6, "Cultural Resources" of the DEIS. Since publication of the DEIS, FTA and PANYNJ have executed a Memorandum of Agreement with specific commitments to avoid, minimize, and/or mitigate adverse impacts to the WTC site. The full text of the MOA is presented in Appendix B of this FEIS, and Chapter 6, "Cultural Resources," summarizes the commitments.

Comment 133: It is unclear exactly what this Figure 2 is attempting to show. (Gardner et al)

Response: Figure 2 reflects the programming of spaces within and immediately adjacent to the WTC site at street-level.

Comment 134: Figure 4 should clearly identify the entire area occupied by the footprints of the Twin Towers as a historic resource. (Gardner et al)

Response: Figure 4 identifies the remaining remnants and structures listed in the Coordinated Determination of Eligibility. Although the Coordinated Determination of Eligibility did not specifically reference the footprints as a remaining remnant or structure on the WTC site, the revised finding of effects presented in Chapter 6, "Cultural Resources," of this FEIS discloses the Preferred Alternative's effects on the footprints. ✳

A. INTRODUCTION AND METHODOLOGY

Section 4(f) of the U.S. Department of Transportation (USDOT) Act of 1966 (49 USC §303) prohibits the Secretary of Transportation from approving any program or project that requires the "use" of 1) any publicly owned land in a public park, recreation area, or wildlife and waterfowl refuge of national state, or local significance, or 2) any land from a historic site of national, state, or local significance (collectively "Section 4(f) resources"), unless there is no feasible and prudent alternative to the use of such land and the project includes all possible planning to minimize harm to the resource.

With respect to the term "use", the USDOT, Federal Transit Administration (FTA) considers three possible ways in which a project could involve a "use" of a resource:

- When land is permanently incorporated into a transportation facility;
- When there is a temporary occupancy of land that is adverse in terms of the statute's preservation purpose; or,
- When there is a constructive use of land.

Constructive use occurs when the project does not directly incorporate land from a Section 4(f) resource, but the project's impacts are so severe that the protected activities, features, or attributes that qualify a resource for protection under Section 4(f) are substantially impaired. Substantial impairment occurs only when the protected activities, features, or attributes of the resource are substantially diminished.

With respect to historic sites, no constructive use would occur when:

- Compliance with the requirements of Section 106 of the National Historic Preservation Act (NHPA; 16 USC §470) results in an agreement with the State Historic Preservation Officer (SHPO) of "no effect" or "no adverse effect";
- The projected noise and vibration levels of the proposed transit project do not exceed the relevant noise and vibration impact criteria; or
- The projected noise levels exceed the thresholds because of existing noise, but the increase in noise due to the project is barely perceptible.

This Section 4(f) evaluation has been prepared pursuant to the finding that the Preferred Alternative for the Permanent WTC PATH Terminal would have an adverse effect on the National Register-eligible WTC site and the Hudson River Bulkhead. The Project may also have temporary vibration impacts to nearby historic structures during its construction and may disturb as yet unverified archaeological resources that could remain on the WTC site.

The sections below describe:

- The applicability of Section 4(f) to the Project;
- The Section 4(f) properties;
- The probable use of the Section 4(f) properties by the Project Alternatives;
- Avoidance alternatives to the use of Section 4(f) properties; and
- Planning efforts to minimize harm to the Section 4(f) properties where avoidance is not feasible or is not prudent.

B. APPLICABILITY OF SECTION 4(f) TO THE PROJECT

As described above, a Section 4(f) evaluation is prepared when a transportation project proposes using land from a publicly owned park, recreation area, wildlife or waterfowl refuge, or from a historic site of national, state, or local significance. Since this Project would not use publicly owned parkland, recreational areas, or wildlife or waterfowl refuges, Section 4(f) does not apply for these types of potential resources. However, the Section 4(f) properties described below may be used during construction and/or operation of the Permanent WTC PATH Terminal.

- The Preferred Alternative would be constructed within the boundaries of the approximately 16-acre WTC site (National Register-eligible) and would therefore use this historic resource;
- The Preferred Alternative would require the use of the Hudson River Bulkhead (State and National Register-eligible);
- The Preferred Alternative may require alteration or removal of as yet determined archaeological resources within the eastern portion of the WTC site.
- The Preferred Alternative's construction may result in vibration impacts to known or potential historic buildings within 90 feet of the Project's construction zone.

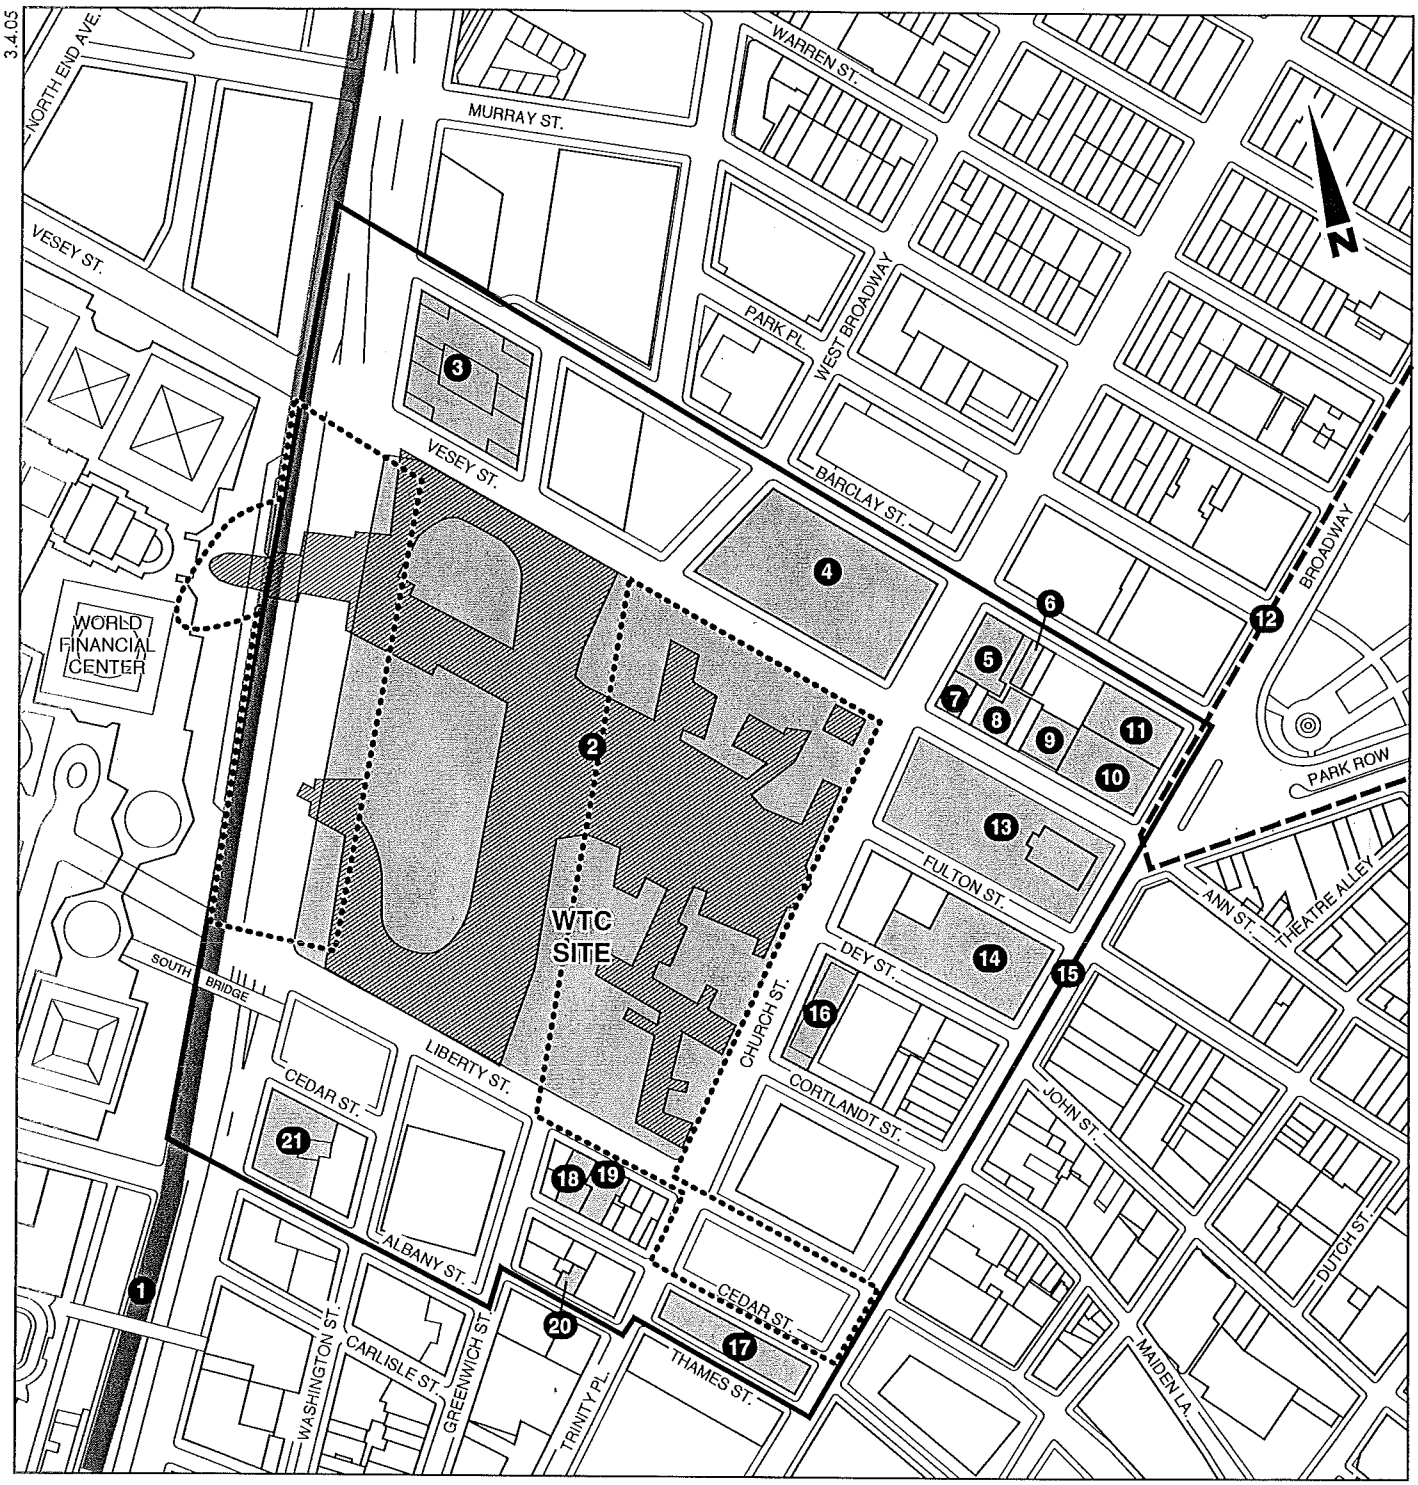
These resources are shown in Figure 4(f)-1

WTC SITE

DESCRIPTION OF THE SECTION 4(f) PROPERTY

The WTC site meets National Register criteria for its association with the September 11, 2001 terrorist attacks on the WTC's two 110-story towers, which on a national level constitute "historic events that have made a significant contribution to the broad patterns of our history." As stated in the Coordinated Determination of Eligibility (DOE) for the WTC site, "the significance of the WTC site is reflected by its integrity of location, setting, feeling, association, and materials" (see Appendix B). The Coordinated DOE also states that some physical remnants on the WTC site possess integrity of materials, including the bathtub, basement walls, and the surviving bases of steel structural columns.

The boundaries of the eligible property are Route 9A, Vesey Street, Church Street, and Liberty Street. Within these boundaries, the site retains various remnants of the former WTC complex and temporary structures introduced as part of the rescue and recovery operations that followed the attacks. As described in the Coordinated DOE, these physical features of the site contribute to its significance. These items include:



Permanent WTC PATH Terminal

Area of Potential Effect

- Tower Perimeter Column Bases (constructed pre-September 11, 2001);
- Bathtub Slurry Walls (constructed pre-September 11, 2001) and Tiebacks (constructed post-September 11, 2001/temporary);
- Northwest Remnant Subgrade Structures (constructed pre-September 11, 2001);
- Recovery and Construction Ramp (constructed post-September 11, 2001/temporary);
- North and South Tunnel Projections from West Wall (constructed pre-September 11, 2001);
- H&M (Hudson & Manhattan) Remnants (constructed pre-September 11, 2001);
- Other Vehicular Ramps (constructed pre-September 11, 2001);
- PATH Tracks and Substation (reconstructed post-September 11, 2001);
- Existing WTC PATH Main Entrance and Concourse, Sidewalks, Fencing, Existing PATH Platforms/Mezzanine (constructed post-September 11, 2001/temporary);
- Passageway to the NYCT WTC Subway Station (E-Train) (constructed pre-September 11, 2001);
- Steel Beams in Cross Form (constructed post-September 11, 2001);
- Plaza and Subway Access from Vesey Street (constructed pre-September 11, 2001); and
- Cooling Water Pipes (constructed pre-September 11, 2001).

PROBABLE USE OF THE SECTION 4(f) PROPERTY

No Action Alternative

Under the No Action alternative, the temporary PATH station would remain in service until either 1) elements of the WTC Memorial and Redevelopment Plan would preclude operations, 2) the station would not safely accommodate passenger demand, or 3) the major elements of the station would exceed their useful service life. In each case, it is assumed that as redevelopment efforts occur in and around the WTC site, modifications to the physical characteristics and operation of the station would be required to maintain temporary PATH service to the extent possible. These modifications may include additional access and egress locations and the construction of ventilation structures should the tracks and platforms be enclosed by the above-construction of the WTC Memorial and Redevelopment Plan.

Preferred Alternative

The Preferred Alternative for a Permanent WTC PATH Terminal would consist of five levels—track and platform, mezzanine, concourse (main), concourse (balcony), and street-level. Elements of the Terminal would be located throughout the WTC site. The proposed tracks and platforms would be in essentially the same location as the temporary WTC PATH station but would be expanded and configured to accommodate a fourth platform and 10-car trains. A mezzanine would be constructed immediately above the tracks and platforms. The concourse would extend in an east-west direction through the site from Route 9A to Church Street with intermediate connections to the Freedom Tower and other elements of the WTC Memorial and Redevelopment Plan. It would also extend in the north-south direction east of the 1 and 9 subway line from the northeast quadrant of the site to Liberty Street. The concourse would provide connections to the Cortlandt Street (R and W), Cortland Street (1 and 9), and World Trade Center (E) subway stations. A street-level terminal building would be constructed west of Church Street between Fulton and Dey Streets.

The Preferred Alternative is being planned to support PATH's system-wide improvements, PATH's operating requirements, and future ridership demand. Each of these factors results in specific requirements for the design of the Terminal's platforms and tracks, and as such, it has been determined that a 5-track, 4-platform station is needed. Further details on the selection of 5-track, 4-platform configuration as well as alternative track and platform schemes evaluated in conjunction with project planning are provided in Appendix C of the FEIS.

The DEIS noted that the removal of portions of the northwest remnant sub-grade structures on the WTC site may be undertaken as part of the Terminal's construction. However, subsequent to the publication of the DEIS, the removal of the northwest remnant sub-grade structures have been undertaken as an independent action pursuant to the stipulations of the Programmatic Agreement prepared for the WTC Memorial and Redevelopment Plan.

The construction of the Preferred Alternative would not alter the location or setting of the WTC site. However, because it may result in the removal or alteration of remaining remnants and structures on the site, it could diminish the site's integrity of feeling, association, and materials (see Appendix B). The following describes the specific impacts of the Preferred Alternative on the various elements of this Section 4(f) resource. The location of these remaining remnants and structures is shown in Figure 4(f)-2.

- ***Tower Perimeter Column Bases with Other Column Bases and Infrastructure*** (constructed pre-September 11, 2001): There were 84 perimeter columns extending into the bedrock that would outline the North Tower façade, and 73 perimeter columns extending into bedrock that would outline the South Tower façade. The original subgrade column grid in the WTC bathtub was configured to span above the former Hudson & Manhattan tunnels traversing the bathtub, as well as the new PATH tracks (there were 84 perimeter columns for the South Tower appearing above grade). In addition, approximately 34 of the South Tower columns were within the existing PATH right-of-way area (interspersed with tracks, electrical equipment, and other infrastructure), and 39 were outside the PATH right-of-way area. During the post-September 11, 2001 emergency recovery operations conducted by the City of New York, all of these Tower perimeter columns were truncated such that only the bases remain. During subsequent construction of the temporary WTC PATH station, all of the column bases within the PATH right-of-way were either obscured to some extent or removed for installation of the temporary WTC PATH station's track sheds, utilities, duct banks, conduits, and other PATH infrastructure.

  As described in the project's Memorandum of Agreement (MOA), PANYNJ shall, to the maximum extent feasible, preserve in place 84 column base remnants in the North Tower and 39 column base remnants in the South Tower at the existing floor at elevation 242 (58 feet below Sea Level) that outline the footprints of the former Twin Towers at the WTC site and are not located in the PATH right-of-way. However, up to 16 column bases in the North Tower and 3 column bases in the South Tower would be temporarily or permanently removed.

  There would be various site infrastructure elements supporting the Preferred Alternative within the PATH right-of-way, including utility lines traversing the outline of the Tower perimeter column bases, and utility rooms and structures located within the area outlined by the perimeter column bases. Although these would not disturb the perimeter column bases themselves, these elements may somewhat impact visibility and accessibility to the Tower perimeter column bases. The Preferred Alternative may also include utility lines that cross the footprints of the former North and South Towers at an elevation above the existing floor

5.21.04

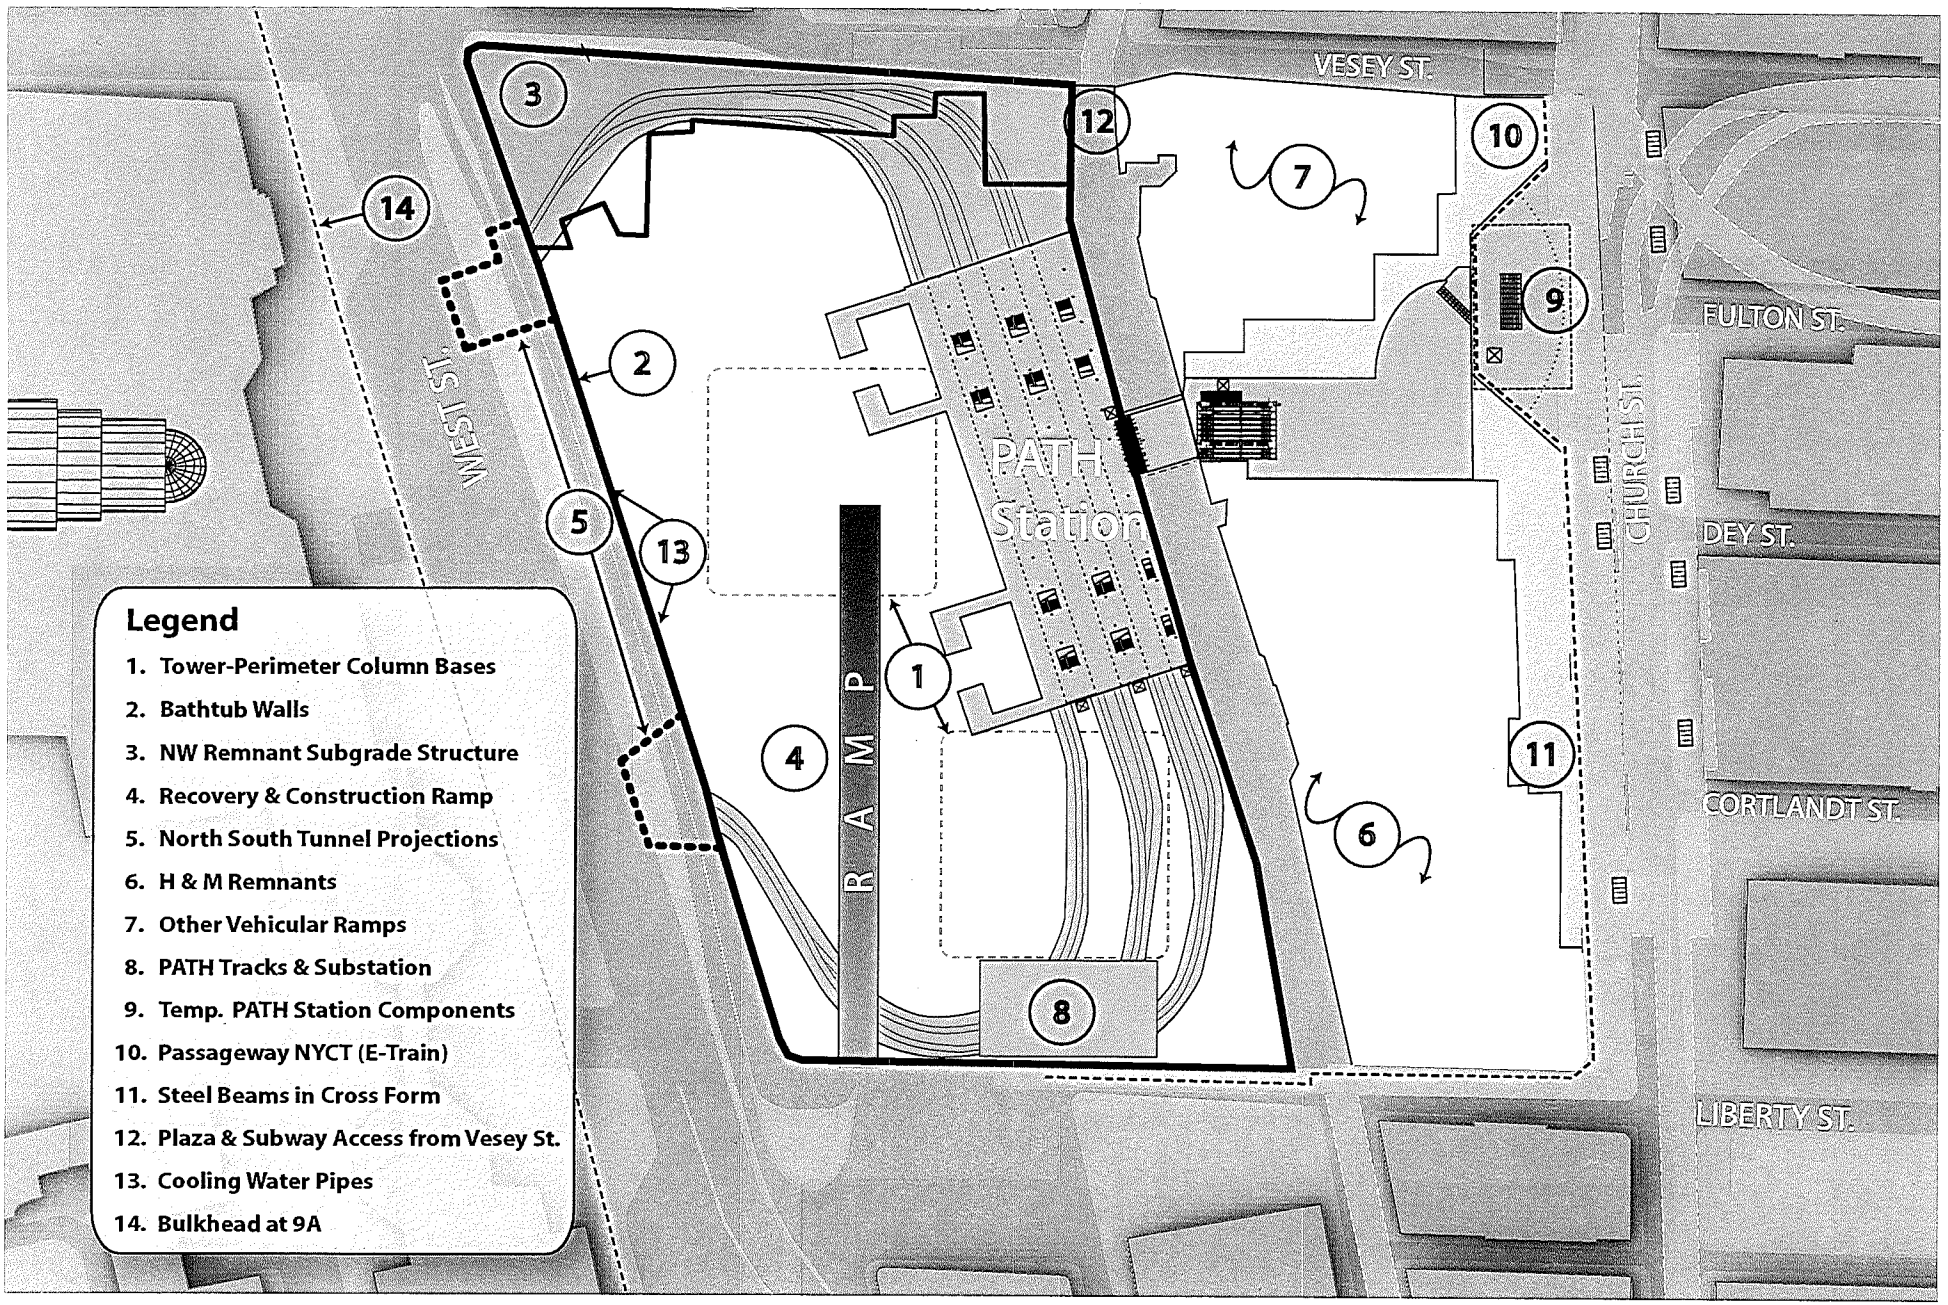

Figure 4(f)-2

Remaining Remnants and Structures on the WTC Site

of the WTC site (Elevation 242 or 58 feet below Sea Level). Under current plans, these utilities would be at Elevation 264 (36 feet below Sea Level). These utility lines would serve the joint infrastructure needs of both the Permanent WTC PATH Terminal and the WTC Memorial and Redevelopment Plan.

The total extent of the North Tower footprint at the lowest level, at approximately elevation 242 (58 feet below sea level) to be permanently occupied by any portion of the Project will be approximately 1,600 square feet and will not exceed 4 percent of the North Tower footprint area. The total extent of the South Tower footprint at the lowest level, at approximately elevation 242 (58 feet below sea level) to be permanently occupied by any portion of the Project will be approximately 21,615 square feet currently occupied by the WTC PATH facility, plus an additional 2,000 square feet required by the Project, and will not exceed 53 percent of the South Tower footprint area.

During the construction of the Preferred Alternative, PANYNJ would install a temporary track west of the existing Track 5. This temporary track would be used to maintain PATH operations while rehabilitation work is undertaken on other PATH tracks. The temporary track would cover column bases and footprint area outside the existing PATH right-of-way during the construction period, but the track would be removed upon completion of the permanent tracks.

- ***Bathtub Walls*** (constructed pre-September 11, 2001) and Tiebacks (constructed post-September 11, 2001/temporary): All four of the slurry walls forming the "bathtub" would require some modification in order to ensure their continued structural function, which is to secure the "basement" of this portion of the WTC site from the high water table resulting from the site's proximity to the Hudson River.

  The Preferred Alternative includes the reinforcement of portions of the basement walls to ensure their structural integrity and to support future redevelopment of the WTC site, including the Permanent WTC PATH Terminal. A portion of the approximately 70 foot high west slurry wall, with tieback caps exposed, is proposed to remain visible and accessible to the public (a separate undertaking), and another portion of the west wall would be pierced (in a location away from the proposed exposed section) for the east-west pedestrian concourse below Route 9A. The remainder of the west wall would be protectively lined as part of the Preferred Alternative. PANYNJ would also reinforce portions of the east bathtub wall abutting NYCT's 1 and 9 line that were not previously reinforced. If other development on the WTC site does not move forward according to current schedules or plans, it may also be necessary to reinforce portions of the north bathtub wall east of Freedom Tower and portions of the south bathtub wall above the existing PATH substation. Where liners are installed, existing tieback caps would remain although their projections would be subsumed within the concrete of the liners.

- ***Recovery and Construction Ramp*** (constructed post-September 11, 2001/temporary): The support foundation for the ramp would be relocated to allow for temporary relocation of an existing track. The ramp would remain during early construction of the Preferred Alternative and would then be removed.

- ***North and South Tunnel Projections from West Wall*** (constructed pre-September 11, 2001): Structural modifications would be made to the projections to accommodate the temporary Track 6.

- ***H&M Remnants*** (constructed pre-September 11, 2001): The cast-iron ring tubes in the east slurry wall of the bathtub would be removed for construction of the Preferred Alternative. On the eastern portion of the WTC site, all or portions of the remnants of the former H&M Terminal building and its powerhouse would be removed to construct a north-south concourse for the Preferred Alternative. Other remnants of these tubes (under the Hudson River) would still remain in service.
- ***Other Vehicular Ramps*** (constructed pre-September 11, 2001): Several of these ramps would be removed or sealed off, as they would have no function under the Preferred Alternative. This would also accommodate construction of new pedestrian concourses.
- ***PATH Tracks and Substation*** (reconstructed post-September 11, 2001): The PATH tracks that are part of the temporary WTC PATH station, would remain but would be further modified for permanent operation and to install a switch to the temporary Track 6. The wiring at the existing substation, also installed as part of the temporary PATH facility, would be modified for the permanent operation.
- ***Existing WTC PATH Station Main Entrance and Concourse, Sidewalks, Fencing, Existing PATH Platforms/Mezzanine*** (constructed post-September 11, 2001/temporary): Portions of these elements would be removed for construction of a permanent entry facility, main transit hall, concourses, PATH mezzanine, and platform levels.
- ***Passageway to the NYCT WTC Subway Station (E-Train)*** (constructed pre-September 11): The passageway between the Terminal and the MTA/NYCT E Subway would be designed to incorporate the existing E Subway entrance in its current location. Certain elements and materials of this passageway, which were retained as part of the construction of the temporary station, would be preserved as part of the Preferred Alternative. However, it may be necessary to remove the doors during construction for their protection. They would be stored until they could be returned to the reconstructed passageway.
- ***Steel Beams in Cross Form*** (post-September 11, 2001): The "steel cross" was moved from the area of 6 WTC to its current location in the eastern portion of the WTC site near the intersection of Church and Cortlandt Streets for public viewing. The cross structure would be removed from this location to accommodate the new north-south pedestrian concourse construction at-grade. The steel beam in cross form would remain in the custody of PANYNJ pending its disposition in accordance with the right of its respective owners.
- ***Plaza and Subway Access from Vesey Street*** (constructed pre-September 11, 2001): The structural remnants of this access from Vesey Street are not permanently stable or functional. However, construction of the Preferred Alternative would not directly impact these elements. Furthermore, as described in the Project's Memorandum of Agreement, PANYNJ would prepare a Resource Protection Plan for the WTC site. This plan would include measures to avoid potential indirect effects on this structure during the Terminal's construction.
- ***Cooling Water Pipes*** (constructed pre-September 11, 2001): The Preferred Alternative would have no impact on the cooling water pipes. However, sections of the existing cooling water pipes may be reconstructed and/or rerouted under a separate undertaking.

These effects to the WTC site would constitute a use of a Section 4(f) resource.

Figure 4(f)-3
Avoidance Alternatives

AVOIDANCE ALTERNATIVES

Four alternatives were considered to avoid the potential adverse effect to the use of the WTC site that would result from the construction of the Preferred Alternative, as shown in Figure 4(f)-3 and as described below:

- Avoidance Alternative 1, No PATH Service to Lower Manhattan;
- Avoidance Alternative 2, Relocate PATH Projections;
- Avoidance Alternative 3, Relocate Terminal Off-site; and
- Avoidance Alternative 4, Relocate Terminal On-site.

As described below, two alternatives that would fully avoid the resource would be feasible but not prudent. The other alternatives may reduce the potential adverse effect to certain contributing elements of the resource, but they would not wholly avoid the use of the Section 4(f) resource. No feasible and prudent alternative could avoid the use of the Section 4(f) resource. Thus, measures to minimize harm were considered.

Avoidance Alternative 1, No PATH Service to Lower Manhattan

The suspension of PATH service to Lower Manhattan would avoid the use of the Section 4(f) property. Under this alternative, PATH would no longer operate between New Jersey and Lower Manhattan but all associated PATH infrastructure would be retained in its current state and service on PATH's Uptown line would be maintained. It is assumed that PATH would operate similar to the six months before the opening of the temporary WTC PATH station with service to Exchange Place. Materials remaining on the WTC site would not be physically altered or removed as a direct result of this alternative.

As was described for the No Action Alternative in this EIS, the full suspension of PATH service to Lower Manhattan would not meet the goals and objectives of this Project as follows:

- *Effectively restore long-term PATH service between New Jersey and Lower Manhattan:* This goal would not be achieved under this avoidance alternative. This alternative would not enhance Lower Manhattan's transportation infrastructure nor would it benefit PATH operations.
- *Establish an intermodal transportation facility in Lower Manhattan:* Because this alternative would not result in construction of a Permanent Terminal for PATH, intermodal connections in Lower Manhattan would not be enhanced as part of this Project. Therefore, this avoidance alternative fails to meet this goal and its objectives.
- *Plan and construct a terminal that would support the redevelopment of Lower Manhattan:* Since this avoidance alternative would not result in a Permanent PATH Terminal in Lower Manhattan, this Project would not directly support the redevelopment of Lower Manhattan. Although other independent actions (e.g., WTC Memorial and Redevelopment Plan; Route 9A Project; Fulton Street Transit Center, etc.) may be pursued as planned, the long-term success of these projects may be jeopardized by the absence of PATH and the transit connections that are part of the Terminal Alternatives. Without a convenient, cost effective transit connection between New Jersey and Lower Manhattan, Lower Manhattan's commercial recovery may never be fully realized.
- *Minimize adverse impacts to the environment:* Although this avoidance alternative would not result in short-term, construction period impacts, it would have long-term adverse effects to the environment as follows:

- The elimination of PATH service to Lower Manhattan and the failure to construct a Permanent Terminal is inconsistent with current, publicly-supported plans and policies for redevelopment of the WTC site and Lower Manhattan as a whole.
- The economic recovery of Lower Manhattan is dependent on the provision of reliable, convenient, and cost effective transit service. The absence of PATH service may reduce the desirability and marketability of Lower Manhattan and could result in the relocation of existing businesses. Thus, this avoidance alternative may have a lasting, negative effect on the economy of Lower Manhattan.
- Assuming that the economic recovery of Lower Manhattan is achieved as planned, the absence of PATH service would result in substantial increases in vehicular traffic and diversions to other modes of transit. As described in Chapter 8, "Transportation," full disruption of PATH service to Lower Manhattan would generate: approximately 1,200 new vehicles (autos, buses, and commuter vans); 6,200 new bus passengers; 8,400 new ferry passengers; 3,600 new passengers on Uptown PATH service; and 9,350 new subway passengers in the AM peak hour. The diversion of passengers from PATH to these other modes would constrain the major roadways and vehicular access points to, from, and within Lower Manhattan and would increase peak hour congestion on commuter buses, commuter rail, uptown PATH service, and city subways.
- The new vehicle trips that would be generated by this alternative would also adversely affect air quality in the New York and New Jersey metropolitan area. In 2025, this avoidance alternative would generate an estimated additional 15.7, 18.0, 1.5, and 236.0 tons per year of volatile organic compounds (VOC), nitrous oxides (NO_x), fine particulates ($PM_{2.5}$), and carbon monoxide (CO), respectively.

Although this alternative is feasible and would avoid the Section 4(f) resources, it is not prudent because it would fail to meet any of goals of this Project.

Avoidance Alternative 2, Relocate PATH Projections

New tunnel projections at a location south of Liberty Street or north of Vesey Street would allow for the construction of PATH tracks and a terminal that would avoid the use of the Section 4(f) resource. To achieve this alternative, new structures would be constructed within the Hudson River between New Jersey and New York. Within New Jersey, new track and tunnels would be necessary to link the new Hudson River tunnels with the remainder of the PATH system. It is assumed that the PATH infrastructure on the WTC site would be retained in its current state and that the other remaining materials would not be physically altered or removed.

The construction of new tunnels under the Hudson River and upland infrastructure in both New York and New Jersey would be very costly (approximately $3 billion) and would take three to four years longer to plan and construct than any of the Terminal Alternatives. Furthermore, this avoidance alternative would not meet some of the goals of this Project as described below:

- *Effectively restore long-term PATH service between New Jersey and Lower Manhattan:* Generally, this goal may be achieved by this avoidance alternative. However, depending upon the selected location for new tunnels and the infrastructure needed to support new track connections, not all of its objectives may be met. Waterfront sites in Lower Manhattan and New Jersey are mostly developed, which limits the location and construction of new PATH infrastructure. Furthermore, since new track connections would be required within New

Jersey, it is assumed that temporary PATH service would have to be disrupted for a period during construction.

- *Establish an intermodal transportation facility in Lower Manhattan:* Although extensive planning would be needed to locate new tracks and a terminal within Lower Manhattan, it may be possible to provide for some intermodal connections. However, it is expected that this alternative would not achieve all of the connections that are proposed as part of the Preferred Alternative.
- *Plan and construct a terminal that would support the redevelopment of Lower Manhattan:* This alternative would allow for the redevelopment of the WTC site, but it may not provide for direct connections to future uses on the site. Furthermore, because Lower Manhattan is fully developed, construction activities outside the WTC site may impact existing structures or may inhibit plans for other sites. Thus, this avoidance alternative may not allow for the redevelopment of Lower Manhattan as currently planned.
- *Minimize adverse impacts to the environment:* This avoidance alternative would result in both short- and long-term adverse impacts to the environment. Depending on the location of the new tunnels and new PATH infrastructure in New Jersey and Lower Manhattan, this alternative has the potential environmental impacts:
  - As described above, the waterfront areas of Jersey City and most of Lower Manhattan are fully developed. Therefore, construction of new Hudson River tunnels and upland connections, including a Terminal building, would temporary disrupt or permanently alter existing land uses.
  - New right-of-way would be required to construct and operate new Hudson River tunnels and their supporting upland infrastructure. This may require the displacement of existing businesses and residents. Furthermore, new tunnels would take much longer to construct than the Preferred Alternative. Thus, this avoidance alternative has a greater likelihood for short-term disruption to businesses in Lower Manhattan as well as Jersey City during the construction period.
  - The construction of PATH infrastructure on new right-of-way has the potential to disturb known or potential historic and archaeological resources in both Lower Manhattan and New Jersey.
  - Because this alternative would physically alter the alignment of PATH, it has the potential to constrain operations both during construction and over the long-term.
  - A new alignment for PATH also has the potential to result in noise and vibration impacts from long-term train operations.
  - The construction of new tunnels within the Hudson River would disturb aquatic species in the Hudson River estuary and has the potential to adversely affect water quality.
  - The excavation of new tunnels for PATH may disturb contaminated soils present in both Jersey City and Lower Manhattan.

Although this alternative is feasible and would avoid the Section 4(f) resource, it is not considered prudent since it would have costs and other impacts of extraordinary magnitude such as a lengthy period of construction, and many adverse effects to the environment.

Avoidance Alternative 3, Relocate Terminal Off-site

Construction of a terminal within Lower Manhattan but outside the limits of the WTC site would reduce the amount of PATH infrastructure on the WTC site, but it would not avoid the use of the Section 4(f) resource. As described in Chapter 2, "Project Alternatives," the Port Authority of New York and New Jersey (PANYNJ) previously explored a terminal location near the intersection of Broadway, Dey Street, and John Street. Under this alternative, PATH tracks and certain supporting infrastructure would be constructed within the WTC site to allow trains to travel between the existing Hudson River tunnel projections and the terminal at Broadway. Given the land and infrastructure constraints east of Church Street, this off-site alternative would require that a stub-end terminal be constructed.

Although this alternative could reduce or eliminate the use of certain portions of the WTC site, it would not wholly avoid the Section 4(f) resource. Furthermore, it would not meet some of the goals of this Project as follows:

- *Effectively restore long-term PATH service between New Jersey and Lower Manhattan:* The stub-end configuration of this terminal would allow for a maximum operating capacity of 20 trains per hour, which would reduce the maximum throughput of the PATH system. Because the tracks leading to the terminal would cross those of the temporary station, the temporary tracks would need to be removed, resulting in the full disruption of PATH service for several months. Thus, this avoidance alternative would result in both short-term and long-term operational constraints for the PATH system.
- *Establish an intermodal transportation facility in Lower Manhattan:* Because this avoidance alternative could result in a new terminal in close proximity to the proposed Fulton Street Transit Center, it would provide for certain intermodal connections in Lower Manhattan. However, since it would be further from the WTC site, the World Financial Center, and trans-Hudson ferry terminals than the Terminal Alternatives, it would not provide for all of the proposed intermodal connections.
- *Plan and construct a terminal that would support the redevelopment of Lower Manhattan:* This alternative would allow for the redevelopment of the WTC site, but it may not provide for direct connections to future uses on the site. Furthermore, because Lower Manhattan is fully developed except at the WTC site, construction activities outside the WTC site may impact existing structures or may inhibit plans for other sites. Thus, this avoidance alternative may not allow for the redevelopment of Lower Manhattan as currently planned.
- *Minimize adverse impacts to the environment:* This avoidance alternative would result in both short- and long-term adverse impacts to the environment as follows:
  - The construction of an above-grade terminal building and below-grade infrastructure for this avoidance alternative would likely require building demolition. Thus, there may be adverse impacts to existing and proposed land uses.
  - PANYNJ would need to acquire new right-of-way and property to construct and operate this alternative. This would likely require the displacement of existing business and possibly residents in order to provide permanent structures for the terminal. Furthermore, temporary displacement and or disruption of businesses would likely be necessary during construction to support staging and other activities.
  - Several historic structures such as the former East River Savings Bank Building, the former American Telephone & Telegraph (AT&T) Building, and the Corbin Building

are located east of the WTC site in the vicinity of the proposed location of this avoidance alternative. Furthermore, the area east of Broadway along John Street is part of the John Street-Maiden Lane Historic District. It is possible that one or more of these structures may be physically altered by construction of a PATH terminal under this alternative. Thus, although this alternative may reduce the effects to the WTC site, it may have impacts on other Section 4(f) resources.

- Construction activities and staging would require temporary street, sidewalk, and lane closures in the vicinity of Dey Street, John Street, and Broadway. This would disrupt vehicular and pedestrian access to businesses and existing transit services and may result in increased congestion at other nearby locations.
- The construction of a terminal in the vicinity of Dey Street and Broadway has the potential to disrupt New York City Transit subway service on the R and W; 4 and 5; J, M and Z; and possibly the 2 and 3 lines when underpinning of subway structures is required. Although this work would be carried out according to New York City Transit guidelines, it may cause off-peak and weekend service disruptions throughout the construction process.
- Because the terminal would be located in any area having many older buildings, there is potential for both short- and long-term adverse noise and vibration impacts. These impacts may result both from the terminal's construction and from train operations.

Thus, while this alternative is considered feasible, it is not prudent. Not only would this alternative not avoid the use of the Section 4(f) resources, but it would also not meet the goals of this Project.

The selection of an off-site location to the north or south of the WTC site would have similar environmental impacts and operational constraints as the Broadway location. Furthermore, because any off-site alternative would require some PATH infrastructure within the WTC site, it would not avoid the use of Section 4(f) resource.

Avoidance Alternative 4, Relocate Terminal On-site

Construction of a terminal at an alternative location on the WTC site would not avoid the use of the Section 4(f) resource. As described in Chapter 2, "Project Alternatives," PANYNJ previously explored two alternative terminal locations within the WTC site—Church Street and Vesey Street.

Avoidance Alternative 4A, Church Street Location

The Church Street location would result in a new terminal on the eastern portion of the WTC site in the approximate location of the former H&M Terminal. The terminal itself would occupy much of the sub-grade levels between Church, Fulton, and Cortlandt Streets, and the 1 and 9 subway line, which are currently programmed for elements of the WTC Memorial and Redevelopment Plan. The track connections between the terminal and the Hudson River tunnels as well as certain ancillary facilities would be located on the western portion of the WTC site.

Not only would this alternative fail to avoid the use of the Section 4(f) resource, it would not meet some of the goals of this Project as follows:

- *Effectively restore long-term PATH service between New Jersey and Lower Manhattan:* This alternative would meet the long-term operational goals of PATH and would allow for temporary service during construction.

- *Establish an intermodal transportation facility in Lower Manhattan:* This avoidance alternative would provide for the intermodal connections to NYCT subways and the Fulton Street Transit Center in the same manner as the Preferred Alternative. However, it would locate PATH further from the World Financial Center and trans-Hudson ferries than would the Preferred Alternative. Furthermore, the vertical circulation within the Church Street option would require a less convenient ascent to street level than the Preferred Alternative since passengers would need to double back several times. Thus, the Church Street option may increase the travel time and level of congestion within the Terminal as compared to the Preferred Alternative.

- *Plan and construct a terminal that would support the redevelopment of Lower Manhattan:* The Church Street location would require the use of sub-grade spaces that are programmed for elements of the WTC Memorial and Redevelopment Plan. As was described in Chapter 2, "Project Alternatives," the use of these spaces may not only reduce the quantity of offices and retail that could be developed on the WTC site, but it would also locate certain building functions such as security and loading at street level. This would be inconsistent with the planning goals for the redevelopment of the site, which seek to centralize building services and security in order to reduce the potential for future incidents on the WTC site. Furthermore, the location of truck docks and other building services at street level would increase noise at the memorial site.

- *Minimize adverse impacts to the environment:* This avoidance alternative would result in nearly the same environmental impacts as the Preferred Alternative.

Although this alternative is considered feasible, it is not prudent. This alternative would not avoid the use of the Section 4(f) resource. Furthermore, it would constrain future development of the WTC site, would have adverse noise and visual impacts on the planned WTC Memorial, and it would degrade the level of customer convenience as compared to the Preferred Alternative. Therefore, this alternative is inconsistent with the goals of this Project.

Avoidance Alternative 4B, Vesey Street Location

The Vesey Street location would result in a new terminal along the north periphery of the WTC site. The terminal itself would extend east-west beneath the 1 and 9 subway line and would occupy much of the sub-grade levels in the northern portion of the site between Vesey and Fulton Streets. The tracks connections to the Hudson River tunnels, certain ancillary facilities, and portions of the terminal would be within the bathtub. The remaining portions of the terminal and its tracks would be located east of the 1 and 9 subway line.

Similar to the Church Street location, this alternative would fail to avoid the use of the Section 4(f) resource. It would also not meet some of the goals of this Project as follows:

- *Effectively restore long-term PATH service between New Jersey and Lower Manhattan:* This alternative would meet the long-term operational goals of PATH, but it would require the full disruption of temporary service during construction. As a result, those commuting between New Jersey and Lower Manhattan would need to pursue alternative modes of travel for several months.

- *Establish an intermodal transportation facility in Lower Manhattan:* This avoidance alternative would provide for the intermodal connections to NYCT subways, the Fulton Street Transit Center, the World Financial Center, and trans-Hudson ferries in a similar manner as the Preferred Alternative.

- *Plan and construct a terminal that would support the redevelopment of Lower Manhattan:* The Vesey Street location would require the use of sub-grade spaces that are programmed for elements of the WTC Memorial and Redevelopment Plan. This may result in the location of building serving and security to street level. Similar to the Church Street location, the location of truck docks and other building services at street level would increase noise at the memorial site and would have adverse visual impacts.
- *Minimize adverse impacts to the environment:* This avoidance alternative would result in nearly the same environmental impacts as the Preferred Alternative.

Although this alternative is considered feasible, it is not prudent. This alternative would not avoid the use of the Section 4(f) resource. Furthermore, it would fully suspend temporary PATH service during construction and would have long-term adverse noise and visual impacts on the planned WTC Memorial. Therefore, this alternative is inconsistent with the goals of this Project.

MEASURES TO MINIMIZE HARM

Absent an avoidance alternative, FTA and PANYNJ would implement measures to minimize harm to this Section 4(f) resource.

Subsequent to the publication of the DEIS, FTA, PANYNJ, SHPO, the Advisory Council on Historic Preservation (ACHP), and the Project's Section 106 consulting parties consulted to develop the Project's Memorandum of Agreement (MOA), which provides for specific commitments to minimize harm to remaining remnants and structures on the WTC site.

The MOA also details the process for documenting all remaining features on the WTC site as well as any artifacts that would be moved from the site during construction of the Permanent WTC PATH Terminal.

Concurrent with the development of the MOA, FTA and PANYNJ have considered alternatives and design modifications for the Preferred Alternative's track and platform level. The intent of this process was to reduce the physical area of the WTC tower footprints that would be obscured by the Preferred Alternative. FTA and PANYNJ have concluded that 5 tracks and 4 platforms are needed within the Terminal to meet the project's goals and objectives, but that a portion of one of the 4 platforms (Platform D) could be narrowed.

The following describes these measures to minimize harm to the Section 4(f) property. The full text of the executed MOA and other supporting materials appear in Appendix B of the FEIS. The process for developing these measures and the MOA itself is described in Section C, "Coordination," of this Final Section 4(f) Evaluation.

WTC Site Documentation

As stated in the MOA, PANYNJ would document the WTC site and its historic features to Level II standards of the Historic American Buildings Survey/Historic American Engineering Record (HABS/HAER) prior to the removal or alteration of any historic features from the WTC site in connection with the undertaking of the Permanent WTC PATH Terminal. This documentation would consist of large-format, black-and-white photography of the site and its historic features as they currently exist; large-format photographic reproduction of selected existing drawings of current conditions and of pre-September 11, 2001 conditions; and a written history and description of the site and its historic features using information previously generated for the

Coordinated DOE for the WTC site as well as the Permanent WTC PATH Terminal's DEIS and FEIS.

PANYNJ would consult with SHPO and HABS/HAER to determine whether particular features warrant measured drawings, and any such drawings would be prepared by an individual with demonstrated experience in the preparation of measured drawings to HABS/HAER standards.

The completed documentation would be submitted to SHPO and HABS/HAER for consideration. The large-format photographs prepared to HABS/HAER standards would consist of the views itemized in Exhibit H, "Schedule of Photographs" of the Project's MOA (see Appendix B of the FEIS).

Tower Perimeter Column Base Remnants

Up to a total of 5 column bases in the North Tower and up to a total of 3 column bases in the South Tower may be temporarily or permanently removed to construct PATH Platform D. Where Platform D would intersect the northeast corner of the North Tower footprint, the platform would be clear of vertical obstructions and architectural treatments would be used to symbolically represent the location of the footprint. A minimum of 5 to a maximum of 7 column bases of the east column line of the North Tower would be visible from Platform D. The viewing area would consist of a glass wall tilted inward from the platform combined with a mirrored wall to the west to provide a view of the column bases from this area of the platform. Appropriate signage, graphics, and lighting would complete the viewing area.

The locations of column remnants of the South Tower that may be permanently obscured by PATH platforms would be symbolically represented on these platforms through architectural treatments that define and differentiate the portions of the infrastructure that are within the Tower footprint areas. These treatments may include color differentiation, texture differentiation, symbolic representation of Tower perimeter column remnants, and/or an emblematic marker designating the location of the historic resource.

In addition to the column bases described above, up to 4 column bases in the North Tower could be temporarily removed by work to install other Project structures and infrastructure. Of the 4 column bases that could be affected by the Project foundation, those column bases that remain in situ undisturbed or are temporarily removed and returned to their original locations would be accessible following the completion of these foundations.

Removing column bases, on either a temporary or permanent basis, would be considered only after practical engineering design options pursuant to Stipulations I.B., 2a, and 2b, to preserve column bases in place have been exhausted. Column bases that are removed would be returned to their original locations if practical engineering design permits. Permanent removal of column bases would only take place as a last resort, and these column bases would be removed and stored in accordance with the stipulations of the MOA.

The east-west pedestrian concourse to the World Financial Center would be designed and built in a manner that avoids the column remnants projecting above the concrete slab that outline the north perimeter of the North Tower and places this corridor at least five (5) feet outside the North Tower footprint as measured from the center line of each projecting column base to the face of the nearest structural support wall.

The temporary PATH track (in addition to the existing 5 tracks) and associated ballast that would be installed on a temporary basis during construction of the Project tracks and platforms and would be removed upon completion of the permanent tracks and platforms to re-expose the

North and South Tower perimeter column remnants and portions of the North and South Tower footprints that may be covered by the temporary track and ballast.

The construction fill currently on the footprints has been temporarily removed for the purposes of documentation of the footprints pursuant to Stipulation I.A. of the MOA, and would be replaced with clean rounded gravel as required after the documentation in order to protect the footprints and column remnants from ongoing construction. Further treatments may be specified in the Project's Resource Protection Plan.

Passageway to the NYCT Subway Station (E Train)

The new pedestrian connection between the Permanent WTC PATH Terminal and the MTA/NYCT WTC E Subway Station would incorporate the existing E subway entrance, in its current location, in a manner that retains existing materials and features of this entrance, including, but not limited to, the handrails, the travertine flooring, the steps and doors separating the E train from the pedestrian connection, and overhead signage, to the extent possible and in accordance with current building codes and Americans with Disabilities Act requirements. The design would include, at a minimum, a plaque identifying the historic features of the E subway entrance. During construction of the new pedestrian connection between the Permanent WTC PATH Terminal and the E Subway Entrance, doors may need to be carefully removed and stored until they can be reinstalled within the new connection.

East and West Slurry Walls

The design for the Project would provide visibility from within the Terminal to a portion of the east or west slurry wall if the following criteria are met: the condition of the slurry wall evokes the image now understood to represent the historic nature of the wall (e.g. tiebacks are part of the area to be exposed, tiebacks project beyond the re-stabilized slurry wall); the exposure which is provided would enable a view of the slurry wall which is clear, recognizable, and respectful of the slurry wall; and the exposure would not pose a safety hazard to the public from exposed finishes of the wall or its components. The design for the east-west pedestrian concourse shall include a location from which the members of the public may view a plaque and photograph of the west slurry wall.

Steel Beams in Cross Form

PANYNJ would relocate the steel column and crossbeam mounted on a concrete pedestal and currently situated within the WTC site near Church Street in accordance with Stipulation VI of the MOA (see Appendix B). The object would remain in the custody and control of PANYNJ, pending final disposition of these artifacts in accordance with the rights of the respective owners.

Resource Protection Plan for the WTC Site

PANYNJ, in consultation with SHPO and in coordination with LMDC and MTA/NYCT, as appropriate, shall develop a WTC Resource Protection Plan for the Permanent WTC PATH Terminal. The plan would be prepared to protect elements of the WTC site that are to remain in situ from inadvertent damage during the Terminal's construction. It would detail the Project's construction procedures and other construction plans for the site. It would provide for an inspection and reporting of the existing condition of elements, establish protection procedures, establish a monitoring program, and establish methods and materials to be used for any repairs. A historic architect who meets the Secretary of the Interior's professional qualifications standards (48 FR 44716) in historic preservation would be part of the design/construction team

and would have the opportunity to review design drawings and specifications prior to construction. The plan would empower the Project's historic architect in consultation with the Chief Engineer of PANYNJ to issue "stop work" orders to prevent any unanticipated damage to historic properties. Recommencement of work would only be permitted once the Chief Engineer of PANYNJ and the historic architect are assured that appropriate modifications have been made to construction techniques to assure that no further damage would occur.

PANYNJ will furnish copies of the Plan to SHPO, ACHP, the National Park Service, and the Section 106 consulting parties for review and comment prior to its implementation.

HUDSON RIVER BULKHEAD

DESCRIPTION OF THE SECTION 4(f) PROPERTY

There is one known archaeological resource in the area where the Preferred Alternative's pedestrian concourse to the World Financial Center would be located—the Hudson River Bulkhead (S/NR-eligible). The bulkhead and its associated structural systems were built between 1871 and 1936 by the New York City Department of Docks. The majority of the construction consisted of masonry walls on a variety of foundation systems, with quarry-faced ashlar granite block forming the visible face along most of the armored frontage. Design of the bulkhead was the responsibility of George B. McClellan, a Civil War general, who became the first Engineer-in-Chief of the Department of Docks. McClellan's plans contemplated the creation of a 250-foot-wide marginal street, from which 60- to 100-foot-wide piers with cargo sheds would project 400 to 500 feet around 150- to 200-foot-wide slips. Initiated to respond to the deteriorated, congested, and silt-filled condition of the waterfront, the carefully built granite walls created a consistent monumental surface to the waterfront that reinforced an image of New York City's commercial prominence. As property was acquired and as commerce warranted, the city built the bulkheads, built or rebuilt pier substructures, and leased redeveloped areas to private companies, which were usually responsible for piershed and headhouse construction. The bulkhead runs from the Battery to West 59th Street. The portion of the bulkhead located within the study area is below-grade along the western edge of Route 9A (see Figure 4(f)-1).

PROBABLE USE OF THE SECTION 4(f) PROPERTY

No Action Alternative

The No Action Alternative may involve minor construction activities to extend the service life of the temporary WTC PATH station, to the extent possible. Most of these activities would be undertaken within the limits of the WTC site and there would be no disturbance to the Hudson River Bulkhead.

Preferred Alternative

Tunneling for a pedestrian concourse under Route 9A would require piercing the Hudson River Bulkhead, which is buried below ground along the western edge of Route 9A. This would constitute a use of this Section 4(f) resource.

AVOIDANCE ALTERNATIVES

Since a pedestrian concourse below Route 9A would not avoid adverse effects to the Hudson River Bulkhead, alternatives were considered to eliminate this potential adverse impact.

Avoidance Alternative 1: At-grade Crossing

Since subsurface construction would not be required for an at-grade crossing, this alternative would not result in adverse impacts to the Hudson River Bulkhead. However, an at-grade crossing would not meet the goals of this Project as follows:

- *Effectively restore long-term PATH service between New Jersey and Lower Manhattan:* The absence of a grade separated crossing at Route 9A would not restore the facilities that existed prior to September 11, 2001. Previously, two pedestrian bridges crossed Route 9A, providing access between the World Financial Center, the World Trade Center, and PATH. Thus, the at-grade crossing would be inconsistent with this goal for the Project.
- *Establish an intermodal transportation facility in Lower Manhattan:* Because the at-grade crossing would not provide for a convenient connection between the World Financial Center and its ferry terminal, which is west of Route 9A, and the multiple transit facilities, including PATH that would be east of Route 9A. This alternative would not be consistent with this goal for the Project.
- *Plan and construct a terminal that would support the redevelopment of Lower Manhattan:* This alternative would allow for the redevelopment of the WTC site, but it may not provide for a convenient connection between the WTC site and PATH and the World Financial Center and Battery Park City. Although the at-grade alternative is not fully inconsistent with this goal, it does not provide for the enhanced pedestrian connections that would be achieved with a pedestrian concourse under or bridge over Route 9A.
- *Minimize adverse impacts to the environment:* This avoidance alternative would result in long-term adverse impacts to the environment as follows:
  - Since all pedestrians traveling between the WTC site and the World Financial Center would cross at grade, this alternative would likely result in adverse impacts to vehicle traffic on Route 9A as well as to pedestrian levels-of-service. Furthermore, the substantial number of trips that would cross at grade would increase the potential for vehicle/pedestrian conflicts, which would degrade the safety of both vehicular and pedestrian travel in Lower Manhattan.

Thus, while this alternative is considered feasible, it is not prudent. Although an at-grade crossing would avoid the use of the Section 4(f) resources, it would not meet the goals of this Project.

Avoidance Alternative 2: Pedestrian Bridge

The DEIS identified a design option that would result in a pedestrian bridge over Route 9A rather than a sub-grade concourse. Subsequent to publication of the DEIS, the pedestrian bridge was removed as a design option for the Preferred Alternative, but it is considered as part of this Final Section 4(f) Evaluation to avoid the use of the Section 4(f) property.

Subsequent to publication of the DEIS, it was determined that a pedestrian bridge would fail to meet some of the project's goals and objectives as follows:

- *Effectively restore long-term PATH service between New Jersey and Lower Manhattan:* This alternative would provide for the same type of connection that was provided between the WTC site and the World Financial Center as existed prior to September 11, 2001. However, a pedestrian bridge does not provide for the same level of service or convenience as a sub-grade concourse. Under the bridge option, pedestrians wishing to travel between the

Permanent WTC PATH Terminal and Battery Park City would need to ascend from the track/platform level to the second level of Freedom Tower, then cross Route 9A via the bridge and descend to street level through the World Financial Center. This results in two additional sets of stairs/escalators as compared to the subgrade concourse, which increases travel time. Furthermore, the bridge necessitates security measures within the Freedom Tower and the Winter Garden that would not be needed for a subgrade concourse since the bridge diverts greater volumes of pedestrian traffic through these facilities than would the subgrade concourse.

- *Establish an intermodal transportation facility in Lower Manhattan:* Although it may be less convenient for some customers than would be a sub-grade concourse, the pedestrian bridge would provide for connections between the World Financial Center and its ferry terminal, which is west of Route 9A, and the multiple transit facilities, including PATH that would be east of Route 9A. Thus, this alternative would be consistent with this goal for the Project.
- *Plan and construct a terminal that would support the redevelopment of Lower Manhattan:* This alternative would allow for the redevelopment of the WTC site, but it may provide a less convenient connection between the WTC site and PATH and the World Financial Center and Battery Park City than would a sub-grade concourse. Although the pedestrian bridge is not fully inconsistent with this goal, it does not provide for the enhanced pedestrian connections that would be achieved with a pedestrian concourse under Route 9A.
- *Minimize adverse impacts to the environment:* This avoidance alternative would result in long-term adverse impacts to the environment as follows:
  - The construction of the bridge's foundations could result in the disturbance or removal of portions of the Hudson River Bulkhead. The bridge's construction could also affect historic resources located within 90 feet of construction limits, which may result in adverse impacts to other structures within the APE for the Permanent WTC PATH Terminal.

Thus, while this alternative is considered feasible, it is not prudent since it results in reduced levels of service for pedestrians and may necessitate additional security measures for Freedom Tower and the Winter Garden.

MEASURES TO MINIMIZE HARM

Absent an avoidance alternative, FTA and PANYNJ would implement measures to minimize harm to this Section 4(f) resource. The project's executed MOA (see Appendix B) details a process to follow to identify and mitigate any adverse impacts on the Hudson River Bulkhead. Because the Hudson River Bulkhead is also located within the APE for the Route 9A Project, PANYNJ would coordinate its treatment plan with NYSDOT. In consultation with SHPO, and as appropriate, NYSDOT, PANYNJ would develop and implement a plan to locate and identify intact portions of the Hudson River Bulkhead that would be affected by construction of the Permanent WTC PATH Terminal's east-west pedestrian connection. In the event that the intact portions of the Hudson River Bulkhead are identified, PANYNJ would, in consultation with the SHPO and NYSDOT, prepare a treatment plan for those portions of the Hudson River Bulkhead to be affected by the Project. The plan would be submitted to SHPO and Section 106 consulting parties for their review and comment prior to implementation.

WTC SITE ARCHAEOLOGY

A Phase IA Archaeological Assessment and a subsequent Topic Intensive Study for the WTC site found former Block 85 (Lots 8-17) at the northeast corner of the site and former Block 60 (Lots 5, 6, and 10) near the southeast corner of the site to be sensitive and to warrant further consideration (see Figure 4[f]-4.) These areas are located outside the former WTC construction footprint and have the potential to contain shaft features (such as privies, cisterns, wells, and cesspools) predating the 1850s that may have survived under former basements. Lots with basements 20 feet or more below grade have a lesser likelihood of shaft feature preservation.

PROBABLE USE OF THE SECTION 4(f) PROPERTY

No Action Alternative

The No Action Alternative may involve minor construction activities to extend the service life of the temporary WTC PATH station, to the extent possible. Most of these activities would be undertaken within the limits of the temporary WTC PATH station. Therefore, this alternative would not disturb or alter the potential archaeological resources within the northeast and southeast portion of the WTC site.

Preferred Alternative

Construction of the Preferred Alternative would impact portions of the WTC site, which has been identified as potentially sensitive for archaeological resources. If National Register-eligible archaeological resources were found to exist, activities that damaged or destroyed those resources would constitute a use of this historic resource.

The regulations specify that Section 4(f) is not applicable for archaeological resources if it is determined that such resources are important because of what can be learned through data recovery rather than through preservation in place. However, the project's MOA provides for stipulations to address potential impacts to these archaeologically sensitive areas pursuant to the project's compliance with Section 106 of the NHPA.

Prior to any Project-related subsurface disturbance at any of the locations that have been determined to be sensitive for historic archaeological resources, PANYNJ will, in consultation with the SHPO, and LMDC as appropriate identify and evaluate the National Register eligibility of any archaeological resources at these locations in accordance with 36 CFR 800.4.

In the event that FTA, in consultation with SHPO, determines that National Register-eligible archaeological resources will be adversely affected by construction of the Preferred Alternative, PANYNJ would, in consultation with FTA, SHPO, and LMDC as appropriate, and the Section 106 consulting parties, develop and implement an Archaeological Resource Treatment Plan for the Project. The Archaeological Resources Treatment Plan and documentation will adhere to the standards established by the Secretary of the Interior's Standards and Guidelines for Archaeology and Historic Preservation (48 FR 44716), including the standards therein for professional qualifications The plan will be submitted to SHPO and Section 106 consulting parties for their review and comment prior to implementation.

At this time, it is not anticipated that the archaeological resources that could be disturbed with the construction of the Preferred Alternative are important for preservation in place. Therefore, Section 4(f) would not apply to these archaeological resources. However, should it be

determined that these resources should be retained in place, PANYNJ and FTA would prepare a separate Section 4(f) evaluation.

OFF-SITE HISTORIC STRUCTURES

DESCRIPTION OF THE SECTION 4(F) PROPERTIES

An area of Potential Effect (APE) for the Permanent WTC PATH Terminal was established to consider the potential short- and long-term impacts to historic structures. This APE was approved by SHPO in March 2004, and includes 21 known historic or archaeological resources as shown in Table 4(f)-1 and Figure 4(f)-1.

The potential effects of the Preferred Alternative on the WTC site and the Hudson River Bulkhead were described above. This section focuses on the other structures within the Permanent WTC PATH Terminal's APE.

PROBABLE USE OF THE SECTION 4(f) PROPERTIES

No Action Alternative

The No Action Alternative is not expected to result in a direct or constructive use of off-site historic resources.

Preferred Alternative

The long-term operation of the Preferred Alternative is not anticipated to result in any use of off-site historic structures. However, the Terminal's construction may result in vibrations that may impact historic structures in close proximity to construction activities.

Per the guidance of the New York City Department of Buildings, historic structures within 90 feet of the Permanent WTC PATH Terminal's project limits were considered to be potentially impacted by construction activities. Based on these guidelines, the Terminal's construction has the potential to adversely impact 5 Section 4(f) properties within its APE as follows:

- Former East River Savings Bank, 26 Cortlandt Street;
- Barcley-Vesey Building, 140 West Street;
- Beard Building, 125 Cedar Street;
- 114-118 Liberty Street; and
- St. Paul's Chapel and Cemetery.

The other off-site structures listed in Table 4(f)-1 are beyond the 90-foot threshold for construction impacts and would not be subject to use of any sort under Section 4(f).

The executed MOA for the Permanent WTC PATH Terminal provides the following stipulations pursuant to potential impacts to the Barclay-Vesey Building, Former East River Savings Bank, Beard Building, St. Paul's Chapel and Graveyard, and 114-118 Liberty Street.

PANYNJ, in consultation with SHPO and Section 106 consulting parties, and in coordination with LMDC and MTA/NYCT, where appropriate, shall develop a Construction Protection Plan (CPP) for the Project. The CPP would set forth measures for the protection and avoidance of structural and architectural damage to these historic properties that may result from construction vibration. The CPP would be based on requirements in the "New York City Department of

PERMANENT WTC PATH TERMINAL
Final Environmental Impact Statement

Notes: Corresponds to Figure 4(f)-1.
NHL: National Historic Landmark.
SR: New York State Register of Historic Places.
NR: National Register of Historic Places.
S/NR-eligible: Site has been found eligible for listing on the New York State and National Registers of Historic Places.
NYCL: New York City Landmark.
NYCL-eligible: LPC has determined that the site appears eligible for NYCL designation.
* The United States Realty Building is listed on the SR only. It is eligible for listing on the NR.

Buildings Technical Policy and Procedure Notice (PPN) #10/88" regarding procedures for the avoidance of damage to historic structures resulting from adjacent construction. The PPN defines adjacent historic structures as being contiguous or within a lateral disturbance of 90 feet from a lot under development or alteration.

The CPP would describe in detail the construction procedures of the Project, as well as the construction procedures associated with other projects under construction in the vicinity of each of these historic properties. It would also provide for the inspecting and reporting of existing conditions at these properties, establish protection procedures, establish a monitoring program to measure vertical and lateral movement and vibration, establish and monitor construction methods to limit vibration; and establish methods and materials to be used for any repairs. The plan shall also specify the implementation of special vibration protection measures to protect

these historic properties from increased vibration levels associated with construction activities. The CPP would provide for a historical architect meeting the Secretary of Interior Standards to supervise implementation of the CPP.

The CPP would empower the historical architect, in consultation with the Chief Engineer of PANYNJ ("The Engineer") to issue "stop work" orders to prevent any damage to historic properties, and any recommencement of work shall only be permitted at such time that the Chief Engineer and historical architect have assurance that the appropriate modifications have been made to the construction technique to assure that no damage would occur to historic properties.

Since measures to avoid substantial impairment of the historic quality of off-site structures protected by Section 4(f) have been incorporated into the Project, this alternative would not require either a direct or constructive use of these structures. The potential impacts to these off-site historic structures under this alternative would be temporary, minor, and repairable.

C. COORDINATION

The FTA is serving as the federal lead agency for this Project under the National Environmental Policy Act (NEPA). PANYNJ a municipal corporate instrumentality and political subdivision of the States of New York and New Jersey, is acting as the Project sponsor.

The NHPA Section 106 review process for the Permanent WTC PATH Terminal began concurrent with its public scoping under NEPA in September 2003. In order to streamline the process for three of the Lower Manhattan Recovery Projects, FTA entered into a coordinated Section 106 review process with the USDOT, Federal Highway Administration (FHWA), lead agency for the Route 9A Project, and the Lower Manhattan Development Corporation (LMDC), lead agency under the U.S. Department of Housing and Urban Development for WTC Memorial and Redevelopment Plan, in December 2003. The three lead agencies jointly notified the SHPO and Advisory Council on Historic Preservation (ACHP) concerning these three Lower Manhattan undertakings and identified potential consulting parties to the Section 106 process. In January and February 2004, FTA, FHWA and LMDC hosted two meetings with consulting parties to discuss the projects and in particular the evaluation of the WTC site for eligibility for inclusion in the National Register of Historic Places. Consulting parties were also offered opportunities to comment on draft versions of the Coordinated DOE for the WTC site, which was issued in final form on March 31, 2004. Upon completion of the Coordinated Determination of Eligibility, the agencies proceeded with their respective projects' Section 106 responsibilities separately.

Subsequently, the FTA determined that the Permanent WTC PATH Terminal would have an adverse effect on the National Register-eligible WTC site and the National and State Register-eligible Hudson River Bulkhead. The FTA also determined that the Permanent WTC PATH Terminal may have adverse effects to off-site historic resources during its construction. As such, PANYNJ and FTA prepared a draft Permanent WTC PATH Terminal Finding of Effects pursuant to Section 106 of the National Historic Preservation Act, which was published as part of the Permanent WTC PATH Terminal's DEIS.

Consulting parties and the general public had the opportunity to comment on this draft Finding of Effects concurrent with the public comment period for this DEIS. FTA and PANYNJ hosted two Section 106 consulting parties meetings, one on June 14, 2004, and one on July 20, 2004. FTA and PANYNJ provided information at these meetings to further clarify the project's effects

on historic resources. The consulting parties commented on the Finding of Effects and provided discussion on measures to avoid, minimize or mitigate these effects.

Following the close of the public comment period on the DEIS, FTA and PANYNJ continued coordination with the Advisory Council on Historic Preservation (ACHP), SHPO, and the other Section 106 consulting parties to develop measures to avoid, minimize, or mitigate adverse effects on the resources identified in the Finding of Effects. One consulting party meeting was held on August 19, 2004, one on November 4, 2004, and one on November 15, 2004 to solicit comments on the draft Memorandum of Agreement (MOA). Another draft version of the MOA was distributed to the consulting parties on December 16, 2004, and the consulting parties were invited to comment in writing.

The consulting parties provided input on the Draft MOA both at the meetings and in writing. The full transcripts of the meetings and the written comment letters appear in Appendix H of the FEIS. The following is a summary of the major issues raised by the consulting parties and how they are addressed in the executed MOA.

- ***Perimeter Column Remnants Outlining North Tower and South Tower Footprints and the Tower Footprint Areas:*** The treatment and accessibility of the perimeter column remnants and footprint areas in the context of the Permanent WTC PATH Terminal was raised at each of the meetings. In response, the MOA contains a set of stipulations regarding FTA and PANYNJ's commitment that, to the maximum extent feasible given project implementation requirements, the design of the Terminal will preserve in place 84 column base remnants in the North Tower and 39 column base remnants in the South Tower at the existing floor at elevation 242 (58' below Sea Level) that outline the footprints of the former Twin Towers at the WTC site and are not located in the PATH right-of-way. The MOA also sets forth the total, not-to-exceed, extent of each of the tower footprints that will be permanently occupied by any portion of the project, and specifies that the east-west pedestrian corridor will be constructed outside the North Tower footprint. The tower perimeter column bases that would remain in place but may be covered by the platform will have symbolic representation, through architectural treatments, of column remnants that may be obscured or permanently removed by the Terminal's platforms.

- ***Cumulative Effects:*** Consulting parties expressed concern about the cumulative effects of multiple undertakings in this area of Lower Manhattan on the WTC site and on other historic properties in the vicinity. Initial drafts of the MOA, as well as the DEIS and FEIS, specified that Construction Protection Plans (CPPs) would be prepared in advance of construction to ensure that buildings adjacent to areas of construction for the Permanent WTC PATH Terminal would not be inadvertently harmed by a variety of factors, including ground-borne vibration. The final MOA takes into account the need to coordinate development and implementation of the CPPs with LMDC, MTA/NYCT and NYSDOT. It also specifically provides for development and implementation of a plan for protection of historic elements of the WTC site during construction activities within the Site, including construction associated with the WTC Memorial and Redevelopment Plan and, as necessary, with the Fulton Street Transit Center and Route 9A. The MOA also sets forth a detailed process for PANYNJ to address cumulative effects on the WTC site during design, and through the first six months of the Terminal's operation.

- ***WTC Site Artifacts:*** A number of consulting parties were concerned about "off-site" artifacts from the WTC site, many of which are in the interim care and custody of PANYNJ at Hangar 17 at JFK International Airport. The inventory and treatment of these off-site

artifacts is not a part of the Permanent WTC PATH station, and their possible use in the WTC Memorial will be coordinated by LMDC. However, the MOA for the WTC PATH station provides a process to be followed in the event that elements now on the WTC site must be removed during construction of the Permanent WTC PATH Terminal.

- ***E-Train Subway Entrance:*** Responding to a number of comments regarding the E-train subway entrance, the MOA specifies that the remains of the pre-September 11, 2001 entrance to the E subway line from the WTC site will be incorporated, to the greatest extent possible consistent with current building codes and Americans with Disabilities Act requirements, into the new pedestrian connection between the Terminal and the subway.
- ***Recordation of the WTC site:*** Consulting parties were very interested in a comprehensive documentation of current conditions on the WTC site prior to construction, As such, recordation of the WTC site is a stipulation of the Permanent WTC PATH Terminal MOA.
- ***Continued Participation of Consulting Parties:*** Consulting parties raised concerns regarding their continued involvement following the execution of the MOA. Consistent with the regulations implementing Section 106 of NHPA, the MOA explicitly provides for continued participation of consulting parties throughout the design process and treatment plans development following the execution of the MOA.

The MOA among the FTA, ACHP, SHPO, PANYNJ, and concurring consulting parties was executed in April 2005.

FTA solicited U.S. Department of the Interior (DOI) review of the Draft Section 4(f) Evaluation, which was published concurrent with the DEIS. In a letter dated, July 30, 2004, DOI agreed with the findings that there are no feasible and prudent alternatives to the proposed project, if project objectives are to be met (see Appendix H). However, DOI could not agree that all planning for measures to minimize harm had been undertaken. DOI recognized that the Project's Section 106 review process was ongoing and that a MOA would be executed prior to publication of the FEIS. DOI has and will continue to have involvement in the Project's Section 106 review process, including the measures developed pursuant to the MOA in order to minimize harm to the Section 4(f) resources.

The executed MOA provides for ongoing coordination with ACHP, SHPO, and the Project's Section 106 Consulting Parties during the design and construction of the Preferred Alternative. This includes review of a Resource Protection Plan, Construction Protection Plans, and HABS/HAER documentation. Design review for the treatment of the Terminal's platforms, the E subway entrance, and the east and west slurry walls will involve SHPO, ACHP, and the Project's Section 106 Consulting Parties. Furthermore, the MOA provides for a process to communicate project information with the Section 106 Consulting Parties as the design moves forward. ✳

B. LAWS, RULES, AND REGULATIONS

FEDERAL

Americans with Disabilities Act of 1990 as amended (ADA; 24 USC §§12101 et seq.).

Clean Air Act of 1970 as amended (CAA; 42 USC §§7401 et seq.).

Clean Water Act of 1977 as amended (33 USC §§1251 et seq.).

Coastal Zone Management Act of 1972 as amended (16 USC §§1451 to 1465).

Endangered Species Act of 1973 as amended (7 USC §136; 16 USC §§460 et seq.)

Executive Order 11988, "Floodplain Management." President James E. Carter, Jr. 24 May 1977.

Executive Order 11900, "Protection of Wetlands." President James E. Carter, Jr. 24 May 1977.

Executive Order 12898, "Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations." President William J. Clinton. 11 February 1994

Executive Order 13274, "Environmental Stewardship and Transportation Infrastructure Project Reviews." President George W. Bush. 18 September 2002.

Magnuson-Stevens Fishery Conservation and Management Act of 1976 as amended (16 USC §§1801 to 1883).

Migratory Bird Treaty Act of 1918 as amended (16 USC §§703 to 712).

National Environmental Policy Act of 1969 as amended (NEPA, 42 USC §§4321 et seq.).

National Historic Preservation Act of 1966 as amended (NHPA; 16 USC §§470 et seq.).

Noise Control Act of 1972 (49 USC §§4901 et. seq.)

Resource Conservation and Recovery Act of 1976 as amended (42 USC §§6901 et seq.).

Section 4(f) of the U.S. Department of Transportation Act of 1966 as amended (49 USC §303).

STATE AND LOCAL

Air Pollution Control Act (ECL §§19-0101 et seq.).

New York State Historic Preservation Act of 1980 (Recreation and Historic Preservation Law §§14.01 et seq.).

State Environmental Quality Review Act of 1975 as ameneded (ECL §§8-0101 et seq.).

State Pollution Discharge Elimination System Act of 1975 as amended (ECL §§17-0801 et seq.).

Governor George E. Pataki State of New YOrk Executive Order 133, "Establishing the Lower Manhattan Construction Center." November 22, 2004.

Waterfront Revitalization of Coastal Areas and Inland Waterways Act of 1982 (Executive Laws §§42-0910 et seq.).

Mayor Abraham D. Beame, New York City Executive Order No. 91 as amended, "City Environmental Quality Review," 1977 as amended.

New York City Landmarks Preservation Code, (Administrative Code of the City of New York §25-301 et seq.).

New York City Noise Control Code (Administrative Code of the City of New York §24-201 et seq.)

C. SUPPORTING DOCUMENTATION

Lower Manhattan Development Corporation, Metropolitan Transportation Authority, New York State Department of Transportation, and Port Authority of New York and New Jersey. "Environmental Analysis Framework for Transportation Recovery Projects in Lower Manhattan." September 2003.

_____. "Lower Manhattan Transportation Recovery Projects Common Environmental Performance Commitments." September 2003.

U.S. Department of Transportation Federal Transit Administration and Port Authority of New York and New Jersey. "Draft Scope: Permanent World Trade Center PATH Terminal Environmental Impact Statement." September 2003.

_____. "Locations Feasibility Analysis." February 2004.

_____. *"Memorandum of Agreement Among the Federal Transit Administration, the New York State Historic Preservation Office, the Advisory Council on Historic Preservation, and the Port Authority of New York and New Jersey Regarding the World Trade Center Transportation Hub (WTC PATH Terminal and Pedestrian Connections) in New York, New York."* April 2005. ✳

This Final Environmental Impact Statement (FEIS) has been widely distributed and is available for review at libraries, community boards, and other locations. Compact disc and/or bound hard copies of the document were distributed to the federal agencies, New York and New Jersey state agencies, New York City agencies, elected officials, and Section 106 consulting parties listed below. A notice of the document's availability was mailed to the major institutions, community groups, interest groups, local businesses, property owners, property managers, and utility companies listed below.

A. LIST OF NOTIFIED PARTIES

FEDERAL AGENCIES

Advisory Council on Historic Preservation (ACHP)*
U.S. Army Corps of Engineers (ACE)
U.S. Department of Commerce, National Marine Fisheries Service (NMFS)
U.S. Department of Homeland Security, Coast Guard (USCG)

New York City Planning Commission (CPC)
New York City Police Department (NYPD)

ELECTED OFFICIALS

CONNECTICUT

U.S. Representative Christopher Shays, District 4**

NEW JERSEY

U.S. Senator Jon Corzine**
U.S. Senator Frank Lautenberg
U.S. Representative Michael Ferguson, District 7

U.S. Representative Rodney Frelinghuysen, District 11
U.S. Representative Robert Menendez, District 13
U.S. Representative William Pascrell, District 8
U.S. Representative Donald A. Payne, District 10
U.S. Representative Steven Rothman, District 9

New Jersey State Governor, Richard J. Codey (Acting)

New Jersey State Assemblymember Donald Kofi Tucker, District 28
New Jersey State Assemblymember Wilfredo Caraballo, District 29
New Jersey State Assemblymember Anthony Chappone, District 31
New Jersey State Assemblymember Mims Hackett, District 27
New Jersey State Assemblymember Vincent Prieto, District 32
New Jersey State Assemblymember Louis Manzo, District 31
New Jersey State Assemblymember John F. McKeon, District 27
New Jersey State Assemblymember William D. Payne, District 29
New Jersey State Assemblymember Joan M. Quigley, District 32
New Jersey State Assemblymember Craig A. Stanley, District 28
New Jersey State Assemblymember Albio Sires, District 33
New Jersey State Assemblymember Brian P. Stack, District 33
New Jersey State Senator Richard J. Codey, District 27
New Jersey State Senator Joseph V. Doria, Jr., District 31
New Jersey State Senator Sharpe James, District 29
New Jersey State Senator Bernard F. Kenny, District 33
New Jersey State Senator Ronald L. Rice, District 28
New Jersey State Senator Nicholas J. Sacco, District 32

Mayor Jerramiah Healy, City of Jersey City
Mayor Joseph V. Doria, Jr., City of Bayonne
Mayor Sharpe James, City of Newark
Mayor Raymond J. McDonough, City of Harrison
Mayor David Roberts, City of Hoboken

NEW YORK

U.S. Senator Hillary Rodham Clinton
U.S. Senator Charles Schumer
U.S. Representative Carolyn Maloney, District 14**
U.S. Representative Jerrold Nadler, District 8**
U.S. Representative Nydia M. Velazquez, District 12
U.S. Representative Susan W. Kelly, District 19
U.S. Representative Brian Higgins, District 27

New York State Governor, George E. Pataki**
New York State Comptroller, Alan G. Hevesi
New York State Attorney General Eliot Spitzer
New York State Senator Diane J. Savino, District 23
New York State Senator Martin Connor, District 25**
New York State Senator Thomas Duane, District 29
New York State Assemblymember Deborah J. Glick, District 66
New York State Assemblymember Sheldon Silver, District 64**

Mayor Michael R. Bloomberg, City of New York, New York**
New York City Comptroller, William Thompson, Jr.
New York City Public Advocate, Betsy Gotbaum
Manhattan Borough President, C. Virginia Fields**
New York City Councilmember Alan J. Gerson, District 1**
New York City Councilmember A. Gifford Miller, District 5
New York City Councilmember Margarita Lopez, District 2
New York City Councilmember Christine Quinn, District 3

SECTION 106 CONSULTING PARTIES

The following reflects groups and organizations involved in the Section 106 process for the Permanent WTC PATH Terminal in addition to the agencies and elected officials identified above by an asterisk (*). The Section 106 Consulting Parties have been notified of the project's NEPA documentation. Certain consulting parties also serve as community interest groups, public interest groups, and local utility owners. However, these groups are listed within this section rather than under subsequent sections of this chapter.

Alliance for Downtown New York, Inc.
American Institute of Architects, New York Chapter
American Planning Association, New York Metro Chapter
Architectural League of New York
Association for a Better New York
BCRE-90 West Street Corp.
BPC United
Cantor Fitzgerald Relief Fund
Community Board 1-Landmarks Committee
Community Board 1-WTC Redevelopment Committee
Coalition of 9/11 Families
Coalition to Save West Street
Consolidated Edison
Families of September 11th
Give Your Voice
Greek Orthodox in America
Historic Districts Council
Imagine New York
Lower Manhattan Cultural Council
Lower Manhattan Emergency Preservation Fund
Municipal Art Society
National Trust for Historic Preservation
New York Historical Society
New York Landmarks Conservancy
New York New Visions
Pace University – Center for Downtown New York
Partnership for New York City
Preservation League of New York State
Rebuild Downtown Our Town (R.dot)
Regional Plan Association/Civic Alliance
September's Mission

Silverstein Properties, Inc.
Skyscraper Safety Campaign
St. Paul's Church
Team Twin Towers
Tribeca Organization
Tribeca Partnership
Van Alen Institute
Verizon Communications
Voices of September 11th
Wall Street Rising
World Monuments Fund
WTC Families for a Proper Burial
WTC Residents Coalition
WTC Survivors' Network

MAJOR INSTITUTIONS, COMMUNITY GROUPS, AND INTEREST GROUPS

Access to the Region's Core Study
AFL-CIO

Glossary of Abbreviations

ACHP	Advisory Council on Historic Preservation (U.S.).
ACE	U.S. Army Corps of Engineers.
ADA	Americans with Disabilities Act of 1990 (42 USC §§12101 et seq).
APE	Area of Potential Effect.
AQI	Air Quality Index.
AQNMP	Air Quality and Noise Management Plan.
ASHRAE	American Society of Heating, Refrigeration, and Air Conditioning Engineers.
AST	Above-ground storage tank.
BBT	Brooklyn-Battery Tunnel.
BID	Business Improvement District.
BMCC	Borough of Manhattan Community College.
BPC	Battery Park City.
BPCA	Battery Park City Authority.
BUD	Beneficial Use Determination.
CAAA	Clean Air Act Amendments of 1990.
CBD	Central Business District.
CDC	Centers for Disease Control and Prevention.
CEPP	Construction Environmental Protection Program (see below).
CEQ	Council on Environmental Quality.
CEQR	City Environmental Quality Review, (Executive Order No. 91 of 1977)
CFR	Code of Federal Regulations.
CMP	Construction Management Plan.
CO	Carbon monoxide.
Con Edison	Consolidated Edison of New York, Inc.
CPC	New York City Planning Commission.
CSO	Combined sewer outfall.
CZMA	Federal Coastal Zone Management Act of 1972 (16 USC §1456).

dB	Decibel, a unit of sound level.
dBA	A weighted decibel. A sound pressure level that incorporates the human ear's sensitivity to pitch.
Decibel (dB)	The unit for measuring noise, which is 10 times the logarithm of the ratio of the sound pressure squared to a standard reference pressure squared.
DEIS	Draft Environmental Impact Statement.
DOHMH	New York City Department of Health and Mental Hygiene.
DOC	Diesel Oxidation Catalyst.
DOE	Determination of Eligibility
DPF	Diesel Particulate Filter.
Downtown Alliance	Alliance for Downtown New York, Inc.
DU	Dwelling unit.
EFH	Essential Fish Habitat.
EDR	Environmental Data Resources.
EIS	Environmental Impact Statement.
EPA	U.S. Environmental Protection Agency.
EPC	Environmental Performance Commitment.
ESDC	Empire State Development Corporation.
FAR	Floor area ratio, the ratio of a building's floor area to its lot size.
FDNY	New York City Fire Department.
FDR	Franklin D. Roosevelt (refers to FDR Drive, the elevated expressway along the East River waterfront of Manhattan).
FEIS	Final Environmental Impact Statement.
FEMA	U.S. Department of Homeland Security, Federal Emergency Management Agency.
FEMP	Federal Energy Management Program.
FHWA	U.S. Department of Transportation, Federal Highway Administration.
FIRE	Finance, Insurance, and Real Estate.
FRA	U.S. Department of Transportation, Federal Railroad Administration.
FSTC	Fulton Street Transit Center.
FTA	U.S. Department of Transportation, Federal Transit Administration.
GAFO	General merchandise, apparel and accessories, furniture and home furnishings, and other comparison goods.
GEIS	Generic Environmental Impact Statement.

gpd	Gallons per day.
GSA	U.S. General Services Administration.
H&M	Hudson and Manhattan (refers to the railroad that operated the Hudson Tubes between New Jersey and New York).
HASP	Health and Safety Plan.
HCM	Highway Capacity Manual.
HDC	New York City Housing Development Corporation.
HEP	Harbor Estuary Program.
HP	Horsepower.
HRPT	Hudson River Park Trust.
HUD	U.S. Department of Housing and Urban Development.
HVAC	Heating, ventilation, and air conditioning.
ICG	Interagency Consultation Group.
IRT	Interagency Review Team.
L_{dn}	An average sound level over the entire day where the nighttime hours are weighted more than those during the daytime.
L_{eq}	Equivalent sound level, or an energy average sound level, usually specified over a period of time. This is the constant sound level that, in a given period, conveys the same sound energy as the actual time-varying sound.
JFK	John F. Kennedy (refers to John F. Kennedy Airport).
LEED	U.S. Green Building Council, Leadership in Energy Efficiency.
LM	Lower Manhattan (refers to Special New York City Zoning District).
LMDC	Lower Manhattan Development Corporation.
LMEPF	Lower Manhattan Emergency Preservation Fund.
LOS	Level of service (see above).
LPC	New York City Landmarks Preservation Commission.
LRTPs	Long-range transportation plans.
LWRP	Local Waterfront Revitalization Program.
mgd	Million gallons per day.
MOA	Memorandum of Agreement.
MOBILE6.2	The latest emissions model developed by the Environmental Protection Agency to compute vehicular exhaust emission factors.
MOU	Memorandum of Understanding.
MPO	Metropolitan Planning Organization.

MPT	Maintenance and Protection of Traffic.
msf	Million square feet.
MSHA	U.S. Department of Labor, Mining Safety and Health Administration.
MTA	Metropolitan Transportation Authority.
NAAQS	National Ambient Air Quality Standards (see below).
NCWPCP	Newtown Creek Water Pollution Control Plant.
NEPA	National Environmental Policy Act of 1969 (42 USC §§4231 et seq).
NJDEP	New Jersey Department of Environmental Protection.
NJ Transit	New Jersey Transit.
NFPA	National Fire Protection Association.
NHL	National Historic Landmark.
NHPA	National Historic Preservation Act of 1966 (16 USC §470).
NJDOT	New Jersey Department of Transportation.
NJTPA	North Jersey Transportation Planning Authority.
NMFS	U.S. Department of Commerce, National Marine Fisheries Service.
NO_2	Nitrogen dioxide; an air pollutant and precursor to ozone.
NO_X	Nitrogen oxides.
NPS	U.S. Department of the Interior, National Park Service.
NR	National Register of Historic Places.
NRDC	National Resources Defense Council.
NYC	New York City.
NYCAS	New York City Audubon Society.
NYCDCP	New York City Department of Planning.
NYCDDC	New York City Department of Design and Construction.
NYCDEP	New York City Department of Environmental Protection.
NYCDOS	New York City Department of Sanitation.
NYCDOT	New York City Department of Transportation.
NYCDPR	New York City Department of Parks and Recreation.
NYCEDC	New York City Economic Development Corporation.
NYCHPD	New York City Department of Housing Preservation and Development.
NYCL	New York City Landmarks and Historic Districts.
NYCRR	New York Codes, Rules and Regulations.
NYCT	Metropolitan Transportation Authority, New York City Transit.

NYDOH	New York City Department of Health.
NYMA	New York Metropolitan Area.
NYMTC	New York Metropolitan Transportation Council.
NYPD	New York Police Department.
NYS	New York State.
NYSDEC	New York State Department of Environmental Conservation.
NYSDOL	New York State Department of Labor.
NYSDOS	New York State Department of State.
NYSDOT	New York State Department of Transportation.
NYSE	New York Stock Exchange.
NYSOGS	New York State Office of General Services.
NYSOPRHP	New York State Office of Parks, Recreation and Historic Preservation.
NYNHP	New York State Natural Heritage Program.
NYU	New York University.
OEM	New York City Office of Emergency Management.
OMB	New York City Office of Management and Budget.
OIG	Office of Inspector General.
OSHA	U.S. Department of Labor, Occupational Safety and Health Administration.
PABT	Port Authority Bus Terminal.
PAC	Public Advisory Committee.
PAHs	Polycyclic aromatic hydrocarbons.
PANYNJ	Port Authority of New York and New Jersey.
PATH	Port Authority Trans-Hudson.
PCBs	Polychlorinated biphenyls.
PM_{10}	Particulate matter of 10 microns or less.
$PM_{2.5}$	Particulate matter of 2.5 microns or less.
PPE	Personal protection equipment.
P.S.	New York City Primary School.
PSE&G	Public Service Energy & Gas.
psf	Per square foot.
REBNY	Real Estate Board of New York.

Route 9A	New York State Highway 9A (refers to the roadway that runs along the western periphery of the World Trade Center site. Route 9A is also referred to as West Street. West Street is used for building addresses along Route 9A in the vicinity of the World Trade Center Site).
RIMS II	Regional Input-Output Modeling System.
RTK	Right-To-Know.
SAV	Submerged aquatic vegetation.
SBA	U.S. Small Business Administration.
SDEIS	Supplemental Draft Environmental Impact Statement.
Section 4(f)	Section 4(f) of the Department of Transportation Act of 1966 (49 USC §303).
Section 106	Section 106 of the National Historic Preservation Act of 1966 (16 USC §470(a)).
SEQRA	New York State Environmental Quality Review Act.
SFP	Square feet per Pedestrian
SHPA	New York State Historic Preservation Act of 1980.
SHPO	State Historic Preservation Officer, a division of the New York State Office of Parks, Recreation, and Historic Preservation.
SIC	Standard Industrial Code.
SIP	State Implementation Plan.
SLM	Sound Level Meter.
S/NR	State and National Registers of Historic Places.
SO_2	Sulfur dioxide; an air pollutant mainly associated with the combustion of sulfur-containing fuels such as diesel and fuel oil.
SPDES	New York State Pollutant Discharge Elimination System (Article 17, Title 8, of the New York State Environmental Conservation Law).
SR	New York State Register of Historic Places.
SWPPP	Stormwater Pollution Prevention Plan.
TAC	Technical Advisory Committee.
TIP	Transportation Improvement Program.
TMP	Traffic Management Plan.
TMU	Tribeca Mixed-Use.
UDC	New York State Urban Development Corporation.
USC	U.S. Code.
USCG	U.S. Department of Homeland Security, Coast Guard.

USDOT	U.S. Department of Transportation.
USGBC	U.S. Green Building Council.
USGS	U.S. Geological Survey.
USFWS	U.S. Department of the Interior, Fish and Wildlife Service.
UST	Underground storage tank.
ULSD	Ultra low-sulfur diesel.
v/c	Volume-to-capacity ratio.
VdB	A unit of measure of vibration in decibels, which are distinct from noise decibels.
VOC	Volatile organic compound.
vph	Vehicles per hour.
WFC	World Financial Center.
WRP	Waterfront Revitalization Program.
WSURA	Washington Street Urban Renewal Area.
WTC	World Trade Center.

Re: *Coordinated Determination of National Register Eligibility—World Trade Center Site*

Dear Consulting Party:

Following review of comments on the February 6, 2004 coordinated determination of eligibility, Lower Manhattan Development Corporation, Federal Highway Administration, and Federal Transit Administration have prepared a revised Coordinated Determination of National Register Eligibility, dated March 31, 2004. A copy of that document is enclosed.

We thank you for your participation in the Section 106 process thus far and the coordinated determination of eligibility. We look forward to continuing consultation in the next steps of the Section 106 process as our respective projects proceed.

Sincerely,

Kevin M. Rampe

COORDINATED DETERMINATION OF NATIONAL REGISTER ELIGIBILITY—WORLD TRADE CENTER SITE NEW YORK CITY, NEW YORK, MARCH 31, 2004

I. INTRODUCTION

This document has been prepared pursuant to Section 106 of the National Historic Preservation Act in association with proposed reconstruction and redevelopment in the area of the approximately 16-acre World Trade Center superblock (WTC Site), bounded generally by Vesey Street on the north, Liberty Street on the south, Route 9A/West Street on the west and Church Street on the east.

The Federal Transit Administration (FTA), Federal Highway Administration (FHWA), and Lower Manhattan Development Corporation (LMDC), as a recipient of funds from U.S. Department of Housing and Urban Development (HUD), are coordinating the Section 106 processes for several proposed undertakings on or adjacent to the WTC Site: Permanent World Trade Center PATH Terminal (FTA with the Port Authority of New York and New Jersey [Port Authority]), World Trade Center Memorial and Redevelopment Plan (LMDC with HUD funding), and Route 9A Reconstruction (FHWA with New York State Department of Transportation [NYSDOT]). The substance of this document will be incorporated by each of the agencies into their respective environmental review documents.

Section 106 requires federal agencies to identify historic properties (e.g. buildings, structures, sites, objects and districts listed in or eligible for inclusion in the National Register of Historic Places) that may be affected by a proposed undertaking. This document focuses on the WTC Site.

Each of these undertakings is subject to environmental review under the National Environmental Policy Act (NEPA) and to review under Section 106. Environmental impact statements are being prepared for each of these independent undertakings. Because each of the undertakings is different and may have different effects, different Areas of Potential Effect (APEs) have been or will be defined for each undertaking. Identification of historic properties elsewhere in the various projects' APEs and the analysis of potential effects on those properties are being conducted separately.

This document includes information gathered in the NEPA scoping processes for the projects and in meetings with the consulting parties held in the offices of the LMDC at One Liberty Plaza, New York, New York, on January 6, 2004, and on February 2, 2004, as well as written comments received by the coordinating agencies through March 8, 2004.

This document is not intended to be an exhaustive history of the development of Lower Manhattan, the WTC, the events that lead up to September 11, 2001, the horrific events of September 11, or the rescue and recovery operations in the wake of those events. There is substantial and ongoing documentation of those events elsewhere in the numerous articles, books, films, and television reports and productions. This document is intended to express why the coordinating agencies have made a determination that the WTC Site is eligible for listing on the National Register of Historic Places. Each agency's environmental review document will include information relating to its specific project site and additional historical information relating to each project.

The coordinating agencies recognize however, that the WTC Site has been substantially altered since the attacks and collapses on September 11 and include an Appendix relating to artifacts removed from the WTC Site and a discussion regarding the current state of the WTC Site.

II. HISTORICAL INFORMATION

A. BACKGROUND

Prior to European contact in the early 17th century, Native Americans speaking a Munsee dialect of the Eastern Algonquin language inhabited Manhattan Island. Native Americans referred to the island of Manhattan as "Minna-atn" which meant "Island of Hills." The first contacts between Native Americans and Europeans occurred when early explorers began to trade with the native population. Dutch trading expeditions had been visiting the Hudson River for many years prior to the founding of New Amsterdam at the southern tip of Manhattan in 1626. These groups made contact with the native population; Robert Juet, who traveled with Henry Hudson on his 1609 voyage, provides in his journal a description of the native population and their trading practices. Dutch colonization in Manhattan began in earnest in 1625 when an expedition of farmers from the Dutch West India Company arrived at the southern tip of Manhattan with the purpose of building a fort and laying out nine Company farms.

Wall Street was once the northern line of land fortification for the settlement and Pearl Street, to the east of the WTC Site, formed the eastern edge of the island. The Hudson River waterfront ran along the approximate location of Greenwich Street today. Because it was a high bluff, shipping and piers were located along the East River. Blocks were largely formed in an irregular pattern as former farms were developed, giving the area its characteristically winding and narrow system of streets. By the end of the 18th century, the island's shoreline had been extended with new land created on fill. The city's waterfront, particularly around the southern portion of the island, was its important trade and business area. Residential areas, concentrated both inland and farther north including Tribeca, were located away from the commercial and industrial uses.

Tribeca is a neighborhood in Lower Manhattan, generally bounded by Canal Street to the north, Broadway to the east, Barclay Street to the south and the Hudson River to the west. The area's name was adopted by real-estate developers in the mid-1970s and stands for "triangle below Canal." Originally farmland, Tribeca was transformed into a residential neighborhood in the early 1800s, including an enclave of stately brick residences surrounding St. John's Park (subsequently redeveloped with a freight depot and now the site of St. John's Rotary and the exit of the Holland Tunnel) on Hudson Street. Bear Market, a fruit and produce market (which became known as Washington Market), opened at the western end of the neighborhood in 1813, and became one of the city's key food suppliers. It came to occupy a full block along Washington Street between Fulton, Vesey, and West Streets, now part of the WTC Site. However, the neighborhood remained primarily residential until the 1840s, when shipping and commerce in Lower Manhattan intensified, attracting business and making the area a major point of transfer. By the 1860s, the area had become a commercial district as the city's commercial core stretched north. The western portion, containing the Washington Market district, became New York's wholesale food center, covering roughly the western half of what is Tribeca today. In 1872, the New York Mercantile Exchange, known first as the Butter and Cheese Exchange of New York, was founded by dairy merchants seeking to standardize the wholesale business. Booming business necessitated the construction of a new structure for the Exchange at the corner of Hudson and Harrison Streets in 1882; the Exchange occupied this location until its move to a larger space in the WTC in 1977 and then again to Battery Park City (BPC). During the 1880s, new warehouses were built to house mercantile exchanges dealing in butter, cheese, and eggs. At the time of construction of the 1884 Washington Market building, a time capsule containing business cards and a note in remembrance of the construction of the market signed by 32 businessmen was buried; this was discovered at the excavation for the WTC. The eastern portion of Tribeca became a central transfer point for textiles and dry goods by the middle of the century, with new stores, factories, and storage houses built to house those uses.

The development of Lower Manhattan as a shipping and mercantile district continued through the late 19th century. At the same time, banks, investment companies, and brokerage firms built corporate offices in Lower Manhattan to be near the trading activity of the New York Stock Exchange (NYSE) and other

financial and trading institutions, creating what is known to this day as New York City's Financial District. Construction of the Brooklyn Bridge was completed in 1883 to link the cities of Brooklyn and New York and to serve a growing Brooklyn population which until then could only travel to Manhattan by ferry. In addition, the bridge opened up trade routes to Brooklyn, Queens, and the remainder of Long Island, which were primarily farmland. At the turn of the century, tall towers began to appear on the Lower Manhattan skyline. In 1898, 15 Park Row became the world's tallest office tower. Subsequently, other large buildings were erected during the first half of the 20th century—among them the Equitable Building, the Woolworth Building, 70 Pine Street, and 40 Wall Street.

During the first half of the 20th century, Tribeca, including the Washington Market, remained a vital commercial district. However, in the 1950s and 1960s, the Tribeca area underwent yet another transformation. Shifts in market and economic trends resulted in the moving away and/or closure of wholesale business, leaving the many warehouses in the area empty. In the 1960s, the city established the Washington Street Urban Renewal Area (WSURA), which transformed Tribeca and adjacent neighborhoods from failing wholesale and industrial uses to new residential and office uses with schools to serve the new community. Artists were the first to make use of the available spacious and lit buildings, with many factories and warehouses converted to residential lofts. Today Tribeca is a fashionable residential district that includes art galleries, upscale shops, and restaurants.

B. THE WORLD TRADE CENTER

The WTC was originally conceived in the early 1960s by the Downtown-Lower Manhattan Development Association. Chase Manhattan Bank chairman David Rockefeller, founder of the development association, and his brother, New York governor Nelson Rockefeller, pushed hard for the project, insisting it would benefit the entire city. In 1962, the States of New York and New Jersey authorized and directed the Port of New York Authority, now known as the Port Authority of New York and New Jersey (the Port Authority), to acquire the Hudson & Manhattan (H&M) Railroad, an interstate public transit system (now known as PATH). That same year, the Port Authority began plans to build the WTC, and selected architect Minoru Yamasaki to design the project, architects Emery Roth & Sons to handle production work, and, at the request of Yamasaki, the firm of Skilling, Helle, Christiansen and Robertson to serve as engineers. The Port Authority envisioned a project with a total of 10 million square feet of office space. To achieve this, Yamasaki considered more than a hundred different building configurations before settling on the concept of twin towers and three lower-rise structures.

A 12-block area was cleared to create the WTC Site. Five city streets were closed, buildings on the site were demolished, and the site was extensively excavated, especially the area west of the No. 1/9 IRT subway line where the "bathtub" that became the base for the Twin Towers was created. The WTC Site, including the Twin Towers, was built around the Hudson Tubes of the H&M Railroad, which traversed the bathtub, without any interruption of train service. A new PATH Terminal and tracks were constructed at a lower level in the bathtub, replacing the Hudson Terminal of the H&M Railroad on Church Street.

STRUCTURAL AND BUILDING FEATURES

Several structural and building features made the construction of the WTC possible. These features are described below and involved the foundations, elevators and structural system.

Foundations

Much of the ground on which the WTC would be located lay on landfill, which had extended the west side of Lower Manhattan into the Hudson River. Roughly half of the WTC would be located where the Hudson River once flowed. As over a million cubic yards of fill would need to be excavated to set the WTC on bedrock, at issue was how to keep the waters of the Hudson River out. John M. Kyle Jr., chief engineer at the Port Authority, is credited with developing a solution by suggesting the use of the slurry trench method. With this method, excavating machines dug a three-foot-wide trench down to bedrock,

roughly 70 feet below street level. These trenches were dug in 22-foot-wide sections. As fill was removed from each section, a slurry of water and bentonite (an expansive clay) was pumped in. The clay naturally plugged any holes in the sides of the dirt walls. A giant reinforcing steel cage was then lowered into the trench with attachment points for reinforcing tiebacks that were later anchored to bedrock outside the wall. Then, concrete was poured into the trench which forced out the temporary slurry as it rose from the bottom up. These three-foot-thick wall sections became known as the bathtub, although it was meant to keep water out, not in. Once the wall was complete, earth from within the bathtub was removed, and was used as fill on which BPC was later built. When the infrastructure inside the bathtub was complete, the tiebacks were severed.

Elevators

A second feature associated with the Twin Towers was the design of express and local elevators. Although the invention of elevators made skyscrapers possible, elevators were thought to limit how high skyscrapers could go—the higher the building, the more people in the building and, therefore, a greater number of elevators would be needed. Additional elevators would occupy more floor space, thus leaving less floor space available to rent. This dilemma was a limiting factor in the development of skyscrapers and is why most skyscrapers seldom climbed beyond 80 stories. In order to maximize floor space and provide enough elevators to support all the office workers, the Twin Towers were divided into three zones for vertical transportation needs. Local elevators for each of these zones were stacked vertically in the core of the building serving the floors within the zone. Large express elevators traveled up to "skylobbies" on the 44th and 78th floors. At these floors passengers would exit the elevators on the side opposite from where they had entered and would cross the lobby to utilize local elevators. Each tower also had two express elevators that went all the way to the top from street level, and a freight elevator that went all the way to the top from the bottom subgrade level. This skylobby system, by separating express and local elevators, maximized efficiency of transport and economy of space.

Structural System

Tube-style construction was used for the Twin Towers whereby structural steel columns were located only along the exterior wall and around the central core of elevator shafts, stairwells and bathrooms. Thus, the exterior walls would carry the vertical loads as well as resisting all lateral winds. This construction method was made possible by the use of high-strength steels that had not been available previously. The vertical load bearing columns were closely spaced and also served as frames for the narrow floor-to-ceiling windows.

The perimeter columns of the Twin Towers extended vertically into the concrete floor of the bathtub, although in certain areas the perimeter column loads were transferred to span over bottom level infrastructure, including the PATH tracks. Therefore, not all of the perimeter columns in the concrete floor of the bathtub were aligned with the actual façade perimeters of the Twin Towers that were visible at grade.

COMPLETION OF WTC

The WTC represented major urban renewal planning of the 1960s. It comprised six buildings, including the 110-story Twin Towers (1 and 2 WTC). These buildings rose over 1,350 feet and were the two tallest buildings in the world when completed in December 1970 and April 1972. The roof of 1 WTC also had a 351.5-foot mast supporting television and FM radio antennae for major public and private broadcasters in New York City. Occupancy of the Twin Towers began in December 1970 at 1 WTC and in April 1972 at 2 WTC.

The WTC also included Four and Five World Trade Center (4 and 5 WTC), both of which were nine-story buildings; the eight-story United States Customs House (6 WTC); and a 22-story hotel (3 WTC), all of which surrounded the Austin J. Tobin Plaza (the Plaza). Directly below the Plaza was the Concourse,

which consisted of a retail mall and transportation hub that provided pedestrian connections to the PATH trains to New Jersey and several subway lines operated by MTA/NYCT. There were six below-grade floors in the bathtub and three below-grade levels on the east side of the WTC Site, providing parking for approximately 2,000 cars, a system of freight servicing and loading, and significant infrastructure and utilities supporting the operation of the WTC's buildings and transportation facilities, including PATH. The six below-grade floor slabs also provided critical lateral stability for the slurry wall of the bathtub. This subgrade area in the bathtub contained various central plant and services and a grid of columns (30-foot by 30-foot in most areas) to support these subgrade slabs and buildings. Certain structural columns, particularly those adjacent to the north and south slurry walls, were placed in accordance with the contours of the bathtub, the PATH tracks, and other infrastructure components. Thus, there were notable exceptions and an irregular pattern in the areas of the PATH tracks at the north and south ends of the WTC bathtub.

Historically, Lower Manhattan's skyline was developed with the most technologically advanced buildings of the time. As skyscraper technology allowed taller buildings to be built, many pioneering buildings were erected in Lower Manhattan, several of which were intended to be—and were—the tallest building in the world, such as the Woolworth Building. These modern skyscrapers were often constructed alongside older low buildings. By the mid 20th-century, the Lower Manhattan skyline was a mix of historic and modern, low and hi-rise structures, demonstrating the evolution of building technology, as well as New York City's changing and growing streetscapes. Although many skyscrapers were located in the immediate vicinity, the new WTC introduced structures of a much larger scale. When completed, the Twin Towers were the most prominent features of the new WTC and Lower Manhattan's skyline

The large volume of soil excavated for the WTC became fill that began the creation of BPC. BPC was originally conceived around the construction of a seven-story megastructure containing urban functions and amenities, including shops, restaurants, schools, parks, rapid transit, utilities, and public and recreational facilities. A partly glassed-in, partly open service spine was designed to run through the length of BPC connecting all the buildings. The BPC area of 23.5 acres was deeded to New York City.

POST WTC COMPLETION

Shortly after the WTC opened, the recession of the mid-1970s began, the local real estate market collapsed, and plans for BPC were halted. However, a movement to reuse old industrial and commercial buildings was well underway to the north in the newly named SoHo neighborhood, a trend which moved to other industrial and commercial districts, including Tribeca. Attracted by spacious floors, large windows, and low rents—and aided by tax abatement—artists led what became a strong trend of converting former industrial space to residential use.

In the late 1970s, the financial industry rebounded. As the real estate market recovered, space, so plentiful a few years earlier, became scarce. A new wave of office construction began. This activity was accompanied by a new Master Plan for BPC in 1979 that would create a mixed commercial and residential development. The 1979 plan introduced sidewalks and extended the street grid toward the Hudson River. The commercial center was moved from the southern end of the WTC Site up to the middle, tying it to the WTC, with residential developments planned to the north and south.

Pursuant to an agreement between the Port Authority and New York State's Battery Park City Authority (BPCA), a climate-controlled pedestrian bridge was built connecting the northern part of the WTC Site with the commercial core of BPC constructed by the BPCA west of the WTC. North of the 16-acre WTC Site proper was Seven World Trade Center (7 WTC), a 47-story office building completed in 1987 over two electrical substations occupied by Consolidated Edison Company of New York, Inc. (Con Edison). 7 WTC was connected to the WTC Site by a pedestrian bridge over Vesey Street.

South of the WTC Site the two blocks fronting Liberty Street between Greenwich Street and Route 9A were occupied by a 39-story office building at 130 Liberty Street, the Church of St. Nicholas at 155 Cedar Street and a parking lot surrounding the church.

On February 26, 1993, at 12:18 pm, a terrorist truck bomb was set off in the public parking garage underneath the WTC killing six individuals, including a pregnant woman, and causing extensive damage to subgrade infrastructure and the hotel (3 WTC). Following the bombing, public parking was eliminated and a security improvements (capital upgrade) program, as well as certain operational security measures were implemented. In 1995, the Port Authority erected a public "World Trade Center Memorial" on the plaza level of the WTC above the blast site and a private memorial area was established in a subgrade level.

By the turn of the 20th century, the WTC was more than 95 percent occupied and a major economic driver in Lower Manhattan and the Twin Towers were symbols of commercial vitality, representing the strength of the Financial District and New York City as a world leader in trade and finance. The WTC also was a symbol of the rebirth of the downtown. The Twin Towers were the most prominent buildings at the WTC and had become cultural icons and important symbols of the nation's global economic power. The sheer height and scale of the towers was a bold architectural statement. The Twin Towers were also one of the country's most widely recognized architectural symbols. Located at the heart of the nation's third-largest business district, the WTC employed over 42,000 workers, and contained approximately 12 million square feet of commercial office space within the Twin Towers and four adjacent office buildings, as well as hotel and conference facilities, open space, and one of the most successful enclosed specialty retail centers in the country.

C. SEPTEMBER 11, 2001

THE ATTACKS

On September 11, 2001, terrorists hijacked three commercial jetliners (two of which departed from Logan International Airport and one of which departed from Washington Dulles International Airport) and used them to destroy the WTC and damage the Pentagon, respectively. An additional commercial jetliner (which departed from Newark Liberty International Airport) was hijacked and subsequently crashed in Pennsylvania.

At 8:46 am, American Airlines Flight 11 carrying 92 people struck the north tower (1 WTC) between floors 94 and 98, with the impact roughly centered on the north face. Almost immediately, national and international media coverage began. At 9:03 am, United Airlines Flight 175 carrying 65 people struck the south tower (2 WTC) between floors 78 and 84 toward the east side of the south face. Each plane banked steeply as it was flown into a tower, causing damage across multiple floors. As the aircraft impacted the buildings, fireballs erupted and jet fuel spread across the impact floors and down interior shaftways, igniting fires.

As the resulting fires raged throughout the upper floors of the two towers, thousands attempted to evacuate the buildings. Anecdotes taken from survivors indicate heroic behavior was commonly displayed. Some mobility-impaired occupants were carried down many flights of stairs by other occupants. There were numerous reports of people frequently stepping aside and temporarily stopping their evacuation to let burned and badly injured occupants pass by. As the occupants evacuated down and out of the buildings, firefighters and first responders were working their way up the stairways toward the fires.

THE COLLAPSES, DESTRUCTION, AND LOSS OF LIFE

At 9:59 am, 56 minutes after it was struck, the south tower collapsed. The north tower continued to stand until 10:29 am when it, too, collapsed.

The collapses of the towers caused destruction of or extensive damage to all the other buildings on the WTC Site as well as several adjacent buildings. Portions of the south tower (2 WTC) fell on the hotel (3 WTC) at the corner of Liberty Street and Route 9A, on the building at the corner of Liberty and Church Streets (4 WTC), on the central plaza and on the surrounding streets and the area south of Liberty Street, including the building and plaza at 130 Liberty Street just to the south of the WTC. When the north tower (1 WTC) collapsed portions fell on 6 WTC, on 5 WTC, on the plaza, and on the surrounding streets and structures west of Route 9A and north of Vesey Street. All mass transit stations and facilities at the WTC Site were destroyed, and service on several lines was shut down until new connections could be established. The aftermath left victims, human remains, building materials and burning debris covering the entire WTC Site (see Photo 1).

Images of these events were broadcast and were recorded by the media as well as by eyewitnesses. These images were seared in the minds of those who survived the events as well as those who witnessed them in person or on television.

North of the WTC Site, damage to 7 WTC resulted in its collapse later that day. South of the WTC Site, the Church of St. Nicholas was destroyed; 130 Liberty Street was severely damaged, and its two-level plaza along Liberty Street was destroyed. Other buildings surrounding the WTC Site, including the Hilton Hotel, Century 21 Department Store and the Federal Office Building/U.S. Post Office on Church Street, Fiterman Hall on Barclay Street, 90 West Street and the Barclay-Vesey (Verizon) Building on Route 9A, and the Winter Garden, the World Financial Center, and Gateway Plaza in BPC were also severely damaged. Material covered a larger area, with the bulk in the immediate area extending north to Chambers Street, east to Nassau/Broad Streets, south to the Battery, and west to the Hudson River waterfront.

While an estimated 15,000 people were evacuated from the WTC Site, approximately 2,749 people in and around the WTC lost their lives including workers, commuters, residents, visitors, those on the hijacked airliners, and rescue personnel. This death toll number includes 343 New York City fire fighters, 23 New York City police officers, 37 members of the Port Authority Police Department, 92 passengers on American Airlines Flight 11 and 65 passengers on United Airlines Flight 175. Tens of thousands of others were evacuated from the immediate area. There was no loss of life in the PATH system, as PATH trains were directed to not offload passengers at the WTC, and service to the WTC was suspended.

THE AFTERMATH, RESCUE AND RECOVERY OPERATIONS

Shortly after the two attacks on the WTC, all flights in the United States were grounded by the order of the Federal Aviation Administration (FAA). The Port Authority of New York and New Jersey Police Department (PAPD) and other Port Authority employees, the New York City Police Department (NYPD), the Fire Department of the City of New York (FDNY), other emergency response personnel, and concerned citizens rushed to respond to these attacks.

In recognition of the disastrous impact of the terrorist attacks, President George W. Bush declared Lower Manhattan a national disaster area and $21 billion in aid was approved by the United States Congress for the repair, restoration, and recovery efforts. These funds were allocated to the Federal Emergency Management Agency (FEMA), FTA, and HUD for specific objectives and grants, to be separately administered by each of the agencies and local project sponsors.

In November 2001, the New York State Urban Development Corporation d/b/a Empire State Development Corporation (ESDC) established the LMDC, to oversee the revitalization and rebuilding of Lower Manhattan. Eight of the 16 members of the Board of Directors of LMDC are nominated by the Governor of the State of New York and eight are nominated by the Mayor of the City of New York. LMDC's activities, including the currently proposed WTC Memorial and Redevelopment Plan, are being funded through grants from HUD made possible under a $2.783 billion appropriation from the United States Congress for the purpose.

The effects of the terrorist attacks were felt throughout the region and the country, leading to an outpouring of support from local, national, and international levels for the physical, financial, and emotional recovery efforts that continue to this day. Roughly 1,600 FEMA workers were dispatched to Lower Manhattan to assist in the recovery effort. Thousands of volunteers came to the area to assist. In the aftermath, the image of the Twin Towers became a symbol of antiterrorist resolve and the collective determination of the city, the state, and the nation called for rebuilding to restore the iconic center of the Financial District and to honor those who died there on September 11, 2001 and on February 26, 1993.

Much of Lower Manhattan south of Houston Street became a restricted area and was cordoned off in the weeks following the attacks for security and recovery reasons. Large streets and parks, including Route 9A, Battery Park, and the Hudson River Park below Houston Street, were taken over by safety installations, emergency vehicles, recovery equipment, and rescue and recovery facilities for extended periods of time. Some streets remain closed or occupied by safety installations and construction equipment. Many of the businesses and residents in the surrounding area were temporarily displaced, and some have not returned. The building at 130 Liberty Street remains standing, damaged and vacant.

The WTC Site as it existed as of noon on September 11 was transformed yet again by the rescue and recovery operations that began immediately after the attacks under the direction of the FEMA and the New York City Department of Design and Construction (DDC). Work continued 24 hours a day, seven days a week. Initial efforts were tremendous and focused on human rescue operations; only eighteen people were rescued from the ruins of the WTC, two of them were injured police officers discovered in the underground retail concourse. The remaining sixteen were all found among the ruins of 1 WTC. Fourteen of them, twelve firefighters, one police officer and one civilian office worker, were found largely unscathed in an intact stairwell section between the second and fourth floors, sandwiched between collapses. The remaining two rescued were two Port Authority employees recovered in the rubble of the north Tower. The second of these two was rescued approximately 27 hours after the collapse and was the last person to emerge alive from the ruins. As the days passed, the likelihood of successful rescue diminished. As of January 2004, the New York City Office of the Chief Medical Examiner (OCME) confirmed the deaths of 2,749 individuals. Nearly 20,000 human remains have been recovered to date, some of which have not been identified. The unidentified remains have been preserved by the OCME. There are more than 1,200 victims for whom no remains have been identified.

Following September 11, 2001, the City of New York maintained primary responsibility for the recovery efforts and coordinated its efforts with other private and governmental entities until June 30, 2002, when recovery efforts concluded and DDC returned the WTC Site to Port Authority control. Approximately 1.8 million tons of damaged structures and materials were removed through the fall, winter, and spring of 2001-2002. Damaged portions of the lower facades of the Twin Towers that were still intact in the aftermath were cut and removed to allow the recovery of human remains. On the east side of the WTC Site, the standing portions of 4 WTC and 5 WTC were demolished with wrecking balls and removed. Removal of the material from building structures above and below ground exposed the 70 foot deep bathtub within the western portion of the WTC Site which had contained the bases of the Twin Towers, the hotel (3 WTC) and the U.S. Customs House (6 WTC) as well as the PATH Terminal and supporting facilities including the parking garage where the explosives were detonated in the 1993 terrorist attack on the WTC.

As material was removed from areas near the WTC and the near-term stability of standing structures was verified, workers and residents were generally allowed to return to the surrounding area. By the beginning of 2002, the restricted area was pushed back west of Broadway and south of Barclay Street and a public viewing platform was constructed on Fulton Street just east of Church Street. The platform remained in place until Church Street was opened and a wide sidewalk/viewing area on the west side of the street (on the eastern edge of the WTC Site) was created. While Liberty, Vesey, and Barclay Streets surrounding the WTC Site remain closed to vehicular traffic, pedestrian paths have been created across Vesey and Liberty Streets from Church Street to Route 9A. Route 9A was re-opened on March 29, 2002, after construction

of an interim roadway allowing the re-opening of the Brooklyn Battery Tunnel. However, some buildings to both the south and the north of the WTC Site remain unoccupied. Most are being repaired or reconstructed. The fate of Fiterman Hall, a building on the north side of Barclay Street being renovated for use by the Borough of Manhattan Community College before September 11, is uncertain.

In order to stabilize and conserve what remained of the WTC Site as well as to protect the health and safety of rescue workers, necessary infrastructure repairs were undertaken concurrently with the recovery efforts, including the temporary stabilization of the slurry wall with over a thousand steel cable tiebacks and flood-proofing portions of the WTC Site primarily along the south, east and west portions of the WTC bathtub. Structural slabs in the northern portion of the bathtub (underneath 6 WTC) were left for interim stabilization of the northern slurry wall. Recovery efforts concluded as of June 30, 2002 when the WTC Site was returned to Port Authority control. MTA/NYCT completed reconstruction of the No. 1/9 subway tunnel in September 2002 and service resumed on that subway line to Lower Manhattan. The Cortlandt Street station within the WTC Site remains closed.

In order to restore service to a major regional transit hub, construction of a temporary WTC PATH station by the Port Authority began in July 2002 upon conclusion of the recovery operations. The station opened for service in November 2003. The temporary WTC PATH station was constructed in substantially the same configuration that existed on the morning of September 11, except that the tracks and platforms are not fully enclosed, and were built to an eight-car length (and not the original 10-car length), and the station is not heated or air-conditioned, has fewer pedestrian and transit connections, and has only one entrance/exit located on Church Street near Vesey Street.

South of the WTC Site, 130 Liberty Street remains vacant and shrouded in black netting. Its plaza and the supporting structure for the plaza were removed, leaving a deep hole in the ground. To the west, the block formerly occupied by St. Nicholas Church and the parking lot was repaved and has been used for site access and construction staging.

Most of the structural steel from the WTC was removed and distributed for recycling under recovery contracts let by DDC. Major pieces of steel from the towers and 7 WTC were taken to the National Institute of Standards and Technology in Gaithersburg, Maryland for analysis. In addition, selected building remnants (structural steel, building materials, and building components including portions of the structural tridents at the lobby level of the North Tower) and artifacts (including crushed emergency and private vehicles, trackage from the PATH and No. 1/9 lines, and a bicycle rack,) were salvaged for possible memorial and museum use and stored by the Port Authority in Hangar 17 at John F. Kennedy International Airport. In October 2002, the Port Authority Board formally acted to approve a program and funding to protect, catalog and store these artifacts. Other artifacts were salvaged by the New York State Museum and are stored at their facility in Albany. The New York State Museum also gave salvaged artifacts to other museums and institutions in New York and New Jersey. (Appendix A discusses artifacts that were removed from the WTC Site, including those stored at the New York State Museum in Albany, NY and at Hangar 17.)

On March 11, 2002, six months after the attacks on WTC, LMDC, the Port Authority, and the City of New York, established an Interim Memorial in Battery Park. The centerpiece of the memorial is the damaged *Sphere*, a bronze sculpture that had stood in the center of the WTC plaza and made available as a result of a donation by the AXA Art Insurance Corporation. Also on March 11, 2002, Governor Pataki and Mayor Bloomberg dedicated the *Tribute in Light*, two banks of 44 spotlights which projected light almost one mile into the night sky near the location of the Twin Towers. The *Tribute in Light* was the result of collaboration between civic organizations and artists from a broad range of disciplines, and could be seen from up to 25 miles around Lower Manhattan. The lighting of the *Tribute in Light* was one of many ceremonies held across the United States that day and continued to illuminate the night sky for 32 days.

Government programs aimed at providing assistance to individuals affected by the events of September 11 were also established in the months following. The Victim Compensation Fund provides economic compensation to families and dependents of victims in lieu of pursuing a civil court case for damages; the Small Business Administration offered low-interest loans to eligible individuals to repair or replace damaged property and personal belongings not covered by insurance; FEMA's Disaster Housing Program made funds and services available to individuals whose homes were uninhabitable, while FEMA and New York State also provided cash grants to those who did not qualify for the Small Business Administration loans; Department of Labor also made funds available for extension of unemployment assistance. Financial assistance provided by individuals and nonprofit organizations such as the American Red Cross, September 11th Fund, Twin Towers Fund, and New York State World Trade Center Relief Fund also proved invaluable in the recovery efforts.

Following July 1, 2002, the Port Authority continued site stabilization measures including necessary slurry wall repairs, structural shoring, de-watering systems, and other work and structural monitoring. The Port Authority also constructed perimeter walkways and a perimeter fence with information panels describing the history of the WTC Site and the area for the thousands of daily visitors to the WTC Site.

In August 2002, Congress appropriated $4.55 billion in federal funding to be provided through FEMA and the FTA for transportation projects in Lower Manhattan. FTA, the lead federal agency, continues to work with the governor of New York and state and local agencies to identify and develop projects using this federal aid.

III. RESOURCE DESCRIPTION

The WTC Site is located on the west side of Lower Manhattan. Occupying approximately 16 acres, the WTC Site is bounded by Vesey Street on the north, Liberty Street on the south, Route 9A/West Street on the west and Church Street on the east. The IRT No. 1/9 subway divides the WTC Site into two parts—a western portion and an eastern portion (see Photo 2). The west portion of the WTC Site contains approximately 11 acres. It is delineated by reinforced concrete walls approximately three feet thick and approximately 70 feet high. Within these walls, the ground was excavated to bedrock for construction of this portion of the WTC and the below-ground PATH Terminal. This foundation structure was early on named the bathtub, the concrete walls serving to seal the basement of this part of the WTC against water seeping from the nearby Hudson River. With removal of the ruined structures and debris following the attacks, the bathtub has been exposed to nearly full view for the first time since it was constructed (see Photos 3 and 4). The slurry walls constructed around the bathtub area are visible in this portion of the WTC Site except where a portion of the substructure of 6 WTC has been left in place to support those walls. The east portion of the WTC Site was not so deeply excavated (and it has a typical basement structure). Along Church Street the east portion is at grade with three below-grade levels.

The following inventory is divided as the WTC Site is divided into west and east portions. Surviving elements of the WTC observed during site visits in November 2003 are listed below. Elements constructed or installed in association with the recovery and stabilization efforts following September 11, as well as elements associated with the temporary PATH station, are also included to provide a complete picture of the WTC Site today.

West Portion of the WTC Site—Bathtub

After the removal of approximately 1.8 million tons of material from the site, the only standing and remaining structure in this portion of the WTC Site was a remnant of the below-grade (basement) levels of 6 WTC, located along Route 9A and Vesey Street. The most visible remnants of the WTC are the slurry walls which surrounded the bathtub.

1. West wall (constructed pre-September 11): This wall was under the roadbed of Route 9A and adjacent to Tower One, the hotel (3 WTC) and 6 WTC. The north end of the wall is partially covered and obscured from view by remnants of the below-grade structure of 6 WTC (see Photo

5). Damage to the wall from September 11 is apparent as is the new concrete used to repair the damage and increase the height of the wall to prevent flooding. Water damage is also apparent on the wall and sections of reinforcement have been exposed. A number of features are visible, including:

a. Vehicular entrance ramps (constructed pre-September 11): Two sets of rectangular openings are located in the west wall. They were the vehicular entrances/exits for the WTC parking garage from ramps formerly in the median of Route 9A—now beneath the northbound lanes of the temporary roadway. They were located at the B2 basement level and are approximately 42 feet above the bathtub floor. The north pair is located just south of the surviving sections of 6 WTC (see Photo 5). The south pair flanks the southern set of cooling water pipes (see Photos 6 and 7). The north ramp of this southern pair (to the right in Photos 6 and 7) was used by the terrorists to drive the vehicle with explosives into the garage in the 1993 attack on the WTC.

b. Cooling Water Pipes (constructed pre-September 11): Openings for two pairs of cooling water intake and outflow pipes are located in the west wall. The pipes painted green are the 60-inch pipes installed with the original construction (see Photos 6 and 7). These two pipelines ran under West Street between the WTC Site and a subterranean Hudson River Water Pump House facility in BPC. Pipes painted blue are the 66-inch pipes installed in the 1990s. These pipes were routed underneath subgrade entrance ramps under West Street/Route 9A and entered the WTC Site underneath Tower One.

c. Tiebacks (installed post-September 11/temporary): Nearly 1,000 temporary tiebacks were installed during the recovery to hold the wall in place when the debris and damaged below-grade structures were removed. Some tiebacks extend as much as 40 feet long and are anchored to bedrock around the bathtub area. All the tiebacks visible on this wall have been capped to protect them.

d. Southern Projection (constructed pre-September 11): This is the largest apparent opening in the wall that is visible (see Photo 8). It is near the southern end of the wall. The structure was used for emergency PATH tunnel egress and ventilation, and also as part of the venting system for the garage, as well as emergency diesel generators, and connected to vent structures that were located in the median of Route 9A. Note there is also a similar projection behind the remnants of the 6 WTC substructure.

e. PATH tunnel access (constructed pre-September 11): This is located in the southern projection for the southern tunnel (see Photo 8). The restored tracks, covered and partially walled, emerge from the southern projection at the bottom of the bathtub. Note the second PATH tunnel is in the northern projection and not visible due to the remnants of the 6 WTC substructure.

f. Egress stairs (constructed post-September 11/temporary): Steel egress stairs for the emergency egress from the PATH Tunnels "E" and "F" are located in the bathtub in the middle of the wall with a emergency walkway access from each tunnel to grade level along Route 9A.

2. South wall (constructed pre-September 11): The south wall was located under the middle of Liberty Street (see Photo 9). It was adjacent to Tower Two. Damage to this wall is also apparent, as are the new concrete repairs and the vertical extension of the wall to prevent flooding.

   a. PATH tracks (constructed post-September 11): The PATH tracks are adjacent to the base of this wall in the same location that they ran prior to September 11, 2001.

   b. PATH substation (constructed post-September 11): This is the new blank-walled structure above the PATH tracks providing the traction power for train operations.

c. Recovery and Construction ramp (constructed post-September 11/temporary): This ramp provides temporary primary construction access for pedestrians and vehicles from street level to the floor of the bathtub, installed in March 2002 during the recovery effort. This is also among the emergency egress routes for the temporary WTC PATH station.

d. Tiebacks (constructed post-September 11/temporary): Tiebacks were installed during the recovery to hold the wall in place when the debris and damaged below-grade structures were removed.

3. East wall (constructed pre-September 11): This wall is visible above the temporary PATH tracks and on either side of the portion of the temporary WTC PATH station in the bathtub (see Photos 9 and 10). September 11 damage as well as new concrete in repaired sections of the wall are distinguishable.

   a. Hudson Tubes (constructed pre-September 11): Two cast-iron ring tubes are located in the east wall. Only the south tube is visible (see Photo 11).

   b. Vehicular access ramp (constructed pre-September 11): A former vehicular ramp into the below-grade service areas on the WTC Site is just west of the east wall (see Photo 12). Inside the WTC Site (at approximately Fulton Street) the ramp connects to and runs through a portion of the one of the original Hudson Tubes. It connected to the outside world on Barclay Street under 7 WTC where trucks entered and exited the WTC.

   c. Temporary WTC PATH station (constructed post-September 11/temporary): The new structure of the temporary WTC PATH station is visible, and is adjacent to the eastern wall of the bathtub (see Photos 13 and 14). The structures are at the same location and elevations as the pre-September 11 station facility. PATH trains enter and exit the station on the track/platform level. Above that is the mezzanine level (also within the bathtub) where the turnstiles are located. Along the west wall of the mezzanine and overlooking the bathtub, the open structure has screen panels that are translucent; they allow light into the mezzanine level but do not obscure most views out to the WTC Site. Printed panels are also located along the walls and have quotes of famous New Yorkers. Four temporary emergency exit staircases lead from the PATH mezzanine to the floor of the bathtub.

4. North wall (constructed pre-September 11): This wall is largely obscured by the remnants of the substructure of 6 WTC.

   a. 6 WTC (constructed pre-September 11): Remnants of the grade level slab, an egress staircase, and six below-grade floors of 6 WTC (Levels B1-B6) are remaining at the north end of the bathtub (see Photo 15). Smoke scars from the September 11 terrorist attacks are visible at levels B1-B5 from the exterior. These areas were used as below-grade parking (see Photos 16 and 17) and have been temporarily stabilized and shored as part of the site recovery following September 11, 2001.

   b. Tiebacks (constructed post-September 11/temporary): Some tiebacks have been installed where slabs have been demolished (see Photo 18). A few tiebacks near the truck access ramp have cables that have not been cut back and capped.

   c. Vehicular access ramp (constructed pre-September 11): This heavily damaged ramp once connected the WTC Site to Barclay Street (under 7 WTC) and is visible in this area.

5. Area within Bathtub: This is the area that was generally excavated to the concrete floor of the bathtub. It is within the slurry walls (see Photos 2-4). Tower One, Tower Two, 3 WTC (the hotel) and 6 WTC all stood above the bathtub. The concrete floor of the bathtub lies over a layer of gravel which varies in thickness depending upon the geology of a particular location within the bathtub. In addition to the portions of 6 WTC and the temporary WTC PATH station, and

operations and maintenance facilities and its elements identified above, other features or structures now present in the bathtub include:

a. Tower perimeter column bases (constructed pre-September 11): The original subgrade column grid for the Twin Towers was configured in the bathtub to span above the former H&M tunnels traversing the bathtub as well as the new PATH tracks. During the recovery and site clean-up, the perimeter column bases that outline the space where the Twin Towers stood (sometimes referred to as footprints) were cut off just at or above the concrete floor of the bathtub, but remnants remain (see Photos 19 and 20). The perimeter outlines of the north tower and south tower are delineated by column bases forming squares. Prior to September 11, 2001, the PATH facility occupied approximately the east half of the south tower's footprint. There were 84 perimeter columns extending into the concrete floor of the bathtub that would outline the north tower and, due to the configuration and crossing of PATH tracks, 73 perimeter columns extending into the concrete floor of the bathtub that outline the south tower. Of the 73 perimeter columns outlining the south tower, 34 of them were in the PATH facility.

b. Other column bases (constructed pre-September 11): These column bases supported other structures or infrastructure that once existed in the bathtub. They include column bases inside the perimeter of the Twin Towers. Most of the columns were arranged in a 30-foot by 30-foot grid pattern, with notable exceptions and an irregular grid pattern occurring in the areas of the PATH tracks at the north and south ends of the WTC bathtub.

c. Other infrastructure (constructed pre-September 11): Other infrastructure including elevator pits, sump pumps, ejector pumps and drainage lines are located within the bathtub area.

East Portion of the WTC Site

This is the portion of the WTC Site outside of the bathtub area. This area is located east of the alignment of Greenwich Street and the restored No. 1/9 subway line which permits service to the Rector and South Ferry Stations. The new temporary WTC PATH station concourse level and street entrance is located in the north half of this area. There are no surviving remnants of buildings 4 WTC and 5 WTC in this area. Features identified in the eastern portion of the WTC Site include the following:

1. Temporary WTC PATH station main entrance (constructed post-September 11): This new structure is entered from Church Street at Fulton Street. The station has a sculptural form, with two wings rising from a central truss supported on two vertical trusses.

2. Temporary WTC PATH station concourse (constructed post-September 11): This is located one level below-grade (see Photo 21). It connects to the pre-existing downtown platform of the NYCT N/R/W line running under Church Street and at the northeast corner of the WTC Site to the NYCT E line.

3. WTC PATH Terminal underpass (constructed pre-September 11): This is a pedestrian underpass connecting the mezzanine level to the concourse level, located under the No. 1/9 subway line, just as it did in the former WTC. This underpass structure itself remained intact despite the destruction and damage of September 11. New escalators were installed post-September 11.

4. Restored NYCT No. 1/9 subway line (constructed post-September 11): A concrete box enclosing the subway tracks, as well as portions of the former Cortlandt Street station, runs north-south across the WTC Site, just east of the slurry wall. The tracks and enclosure were completely rebuilt after September 11.

5. Plaza and subway access from Vesey Street (constructed pre-September 11): The heavily damaged stair and escalator structure on Vesey Street lead up to the WTC plaza and the bridge to 7 WTC (see Photo 22). It also provided access to the No. 1/9 Cortlandt Street subway station which was under the WTC.

6. Remnants of the Hudson Terminal and the H&M Railroad (constructed pre-September 11): These are found below grade in the middle of the WTC Site along Church Street between Fulton and Cortlandt Streets. When the new WTC PATH Terminal opened in 1971, unused portions of the Hudson Tubes were converted to truck ramps. Sections of these unused portions of the cast-iron tubes exist on site. Below-grade portions of the former terminal that were used for truck loading, parking, and commercial storage also exist on site. All components of the former H&M Terminal substation have been removed (during construction of the WTC), and only large openings in the ground where these features were located survive.
7. Sidewalks and fencing (constructed post-September 11): These sidewalks and fencing are located around the perimeter of the WTC Site.
8. Passageway to the NYCT WTC subway station (constructed pre-September 11): Remnants of the WTC passageway to the E subway line are located below-grade and include steps, a ramp, doors and flooring (see Photos 23 and 24). This passageway has been reopened and connects with the temporary WTC PATH station.
9. Steel cross (erected post-September 11): A section of two connected beams forming a steel cross was found near 6 WTC and erected by recovery workers on the WTC Site.

IV. NATIONAL REGISTER ELIGIBILITY EVALUATION

The WTC Site meets National Register Criterion A for its association with the September 11, 2001 attacks on the two 110-story towers of the WTC which on local, state and national levels constitute "historic events that have made a significant contribution to the broad patterns of our history." In connection with the events of September 11, the WTC Site is significant in the areas of political and government issues, social history and economic history. The WTC Site is exceptionally significant in the history of the United States as the location of events that immediately and profoundly influenced the lives of millions of American citizens and for its role in symbolizing and commemorating those events for survivors, families of victims, New Yorkers, Americans and visitors from all over the world. The WTC Site is defined as the approximately 16-acre property bounded by Route 9A (West Street), and Vesey, Liberty, and Church Streets.

Although the events of September 11 occurred just over two years ago, the WTC Site meets the requirement of National Register Criteria Consideration G that a property achieving significance within the last 50 years must be of exceptional importance. The flying of two large commercial jetliners into the WTC's Twin Towers were the acts that precipitated numerous events of great magnitude, among them the deaths of an unprecedented number of individuals in a single location resulting from foreign attacks on American soil, and also actions, still unfolding, taken by the United States both at home and abroad in response to the attacks themselves and to the issues of global terrorism of which they were a part. The ultimate historical importance of the various events and actions resulting from the attacks has yet to be fully determined, since they are still underway and additional actions are likely to be initiated in the foreseeable future. However, there exists more than sufficient information at this time to document the exceptional importance of the attacks on the WTC to the history of the United States in the 21st century.

The attacks on the Twin Towers on September 11 caused the death of what is currently estimated to have been nearly 2,800 people and when taken together with the attack on the Pentagon and the crash of hijacked Flight 93 in Shanksville, PA, the total rises to more than 3,000. An immediate result of the attacks was a profound transformation in both local and national security. Shortly after the attacks, the FAA grounded all flights then within United States airspace and turned back all flights then coming into the country—something that it had never done before and that continued for several days after September 11. The United States Office of Homeland Security (which later became the Department of Homeland Security) was established on October 8, 2001. In early October 2001, the United States and other members of the international community attacked and then invaded Afghanistan, where the governing

Taliban regime harbored terrorist leaders and training camps. The comprehensive federal response to the events of September 11 also included Congressional enactment of major legislation such as the Aviation and Transportation Security Act, National Construction Safety Team Act, Air Transportation Safety and System Stabilization Act, the United States Patriot Act, and the Terrorism Risk Insurance Act of 2002, as well as major changes in foreign policy.

The significance of the WTC Site is enhanced by the fact that the collapses of the Twin Towers was captured on film, witnessed on television by millions of people as it occurred, and has been replayed countless times all over the world. As such, the image has been indelibly burned into our collective memory, and the WTC Site is a compelling reminder of the tragic events of that terrible day.

In addition to its direct association with the events of September 11, the WTC Site has already acquired significance as the primary place for commemorating the events that transpired there. Almost from the day of the attacks, crowds of people from all over the world, representing diverse cultures, nationalities, and classes, have journeyed to the WTC Site to pay their respects to the victims and bear witness to the significance of the events. It has been the location of countless memorials, ceremonial events, and private pilgrimages by the families of the victims, survivors, rescue workers, government officials, world leaders, and citizens of New York, the nation, and the world. On each of the two subsequent anniversaries of the attacks, the name of each of the victims has been read aloud at the WTC Site, thus publicly proclaiming the collective grief of a nation.

The period of significance begins on September 11, 2001, the day on which the attacks occurred, and continues to June 30, 2002, the date on which DDC concluded the recovery efforts and returned the WTC Site to Port Authority control. Absent the events of September 11, the Twin Towers would not have collapsed, thousands of people would not have lost their lives, the WTC and several adjacent buildings would not have been destroyed or extensively damaged, the massive search, rescue and recovery efforts would not have taken place, the PATH system and the No. 1/9 subway line and station below the towers would have remained in operation, and the numerous actions taken by the United States at home and abroad in the name of national security and war on terrorism would not have taken place (or, with regard to the latter, not in the manner they have to date).

The WTC Site was the locus of the events of September 11 and the significance of those events and their aftermath to American history makes the WTC Site eligible for National Register listing, even at this early date. Although the existing elements on the site do not fully express the scale or catastrophic nature of the events of the day, various remnants of the WTC's Twin Towers and other structures help convey in different ways the events of September 11 and their aftermath and, therefore contribute to the WTC Site's historic significance.

Foremost among these items are the truncated box-beam column bases that help define the perimeter or "footprints" of the former Twin Towers and the slurry walls that form the sides of the underground bathtub for the Twin Towers. The truncated box-beam column bases serve to poignantly delineate the areas where so many lives were lost that day. As revealed by the recovery efforts, the west wall in particular helps to convey the scale of both the bathtub and the destruction wrought on September 11.

Other items also contribute to the understanding of the events in a different way. The remnants of the parking garage contain slabs and interior columns charred with smoke from the fires that burned for months. The beams forming a cross erected by recovery workers reflect the faith and dedication of thousands of rescue and recovery workers both on September 11 and in the months following.

Other remnants, such as the portion of the concrete steps and escalator ramp from Vesey Street to the subway and the remaining portion of the passageway to the E subway line, serve as reminders that the WTC Site was not limited to the Twin Towers and included both pedestrian and transit connections to the surrounding communities.

The significance of the WTC Site is reflected by its integrity of location, setting, feeling, association, and materials. Physical remnants on the WTC Site possess integrity of materials that convey the catastrophic

events of September 11. The WTC Site retains integrity of location, as it is the location of the now-destroyed complex where the September 11 attacks occurred. It also retains integrity of setting. Although buildings and infrastructure within the WTC were destroyed and their ruins removed, the physical environment surrounding the WTC Site remains essentially as it was on September 11, for example its relationship to other buildings in the neighborhood and its location near the Hudson River in Lower Manhattan (a location that necessitated the construction of the slurry walls and bathtub visible today). The WTC Site retains integrity of feeling—the surviving physical features at the site, including the large bathtub, slurry walls, and the bases of steel columns, as they have been revealed by the rescue and recovery efforts, convey the destruction that took place on September 11. The WTC Site also retains integrity of association, which is the direct link between an important historic event and a historic property. The Twin Towers were the targets of these September 11 attacks, and physical features surviving on this site that have material integrity retain their quality of association with the profound events of that day, as well as the post September 11 recovery effort.

The WTC Site is significant due to the extraordinary and catastrophic events of September 11, 2001. These events are important at the local, state and national levels due to the people who died and who gave their lives trying to help others, the physical destruction of the WTC and the unprecedented recovery effort. During the recovery, surviving elements of the WTC were disassembled and removed as part of the search and rescue operations; these actions also contribute to the site's significance. Some of these artifacts (as described in Appendix A) could also contribute to the site's significance if returned to the WTC Site to convey aspects of the events that give rise to the site's eligibility. The individual project sponsors will consider the reuse and interpretative value of artifacts as they further develop their undertakings.

BOUNDARY DESCRIPTION AND JUSTIFICATION FOR THE NATIONAL REGISTER-ELIGIBLE WTC SITE

The boundaries of the eligible property are contiguous with the boundaries of the WTC Site. The WTC Site was the immediate setting in terms of historical development, design and function for the 110-story Twin Towers, which were the specific objectives of the terrorist attacks, and is the primary area onto which they collapsed on September 11. The targets of the attacks, the area that suffered the most catastrophic loss of lives and buildings, and the location most widely recognized for its association with the attacks, is the 16 acres once occupied by the WTC. This area most directly and outstandingly represents the events of September 11. The WTC Site is also associated with the extensive recovery effort that continued on the WTC Site until June 30, 2002.

- Shinnecock Nation Cultural Center and Museum, Winonah Warren
- Voices of September 11th, Mary Fetchet, President

APPENDIX A—ARTIFACTS

During the rescue and recovery operations, a number of artifacts were removed from the WTC Site. Artifacts are the materials that were identified, secured, and preserved. This section deals with those artifacts that were taken from the WTC Site during the recovery efforts. A structure or pieces of a structure or a site removed from their historic location would not usually be considered for National Register eligibility because they have lost their integrity of location. However, based on consultation between the State Historic Preservation Office and the National Park Service, it has been determined that if artifacts are returned to the WTC Site, then they could be considered to contribute to the historic significance of the property.

Of the artifacts removed from the WTC Site one of the most famous is the Sphere, an artwork by Fritz Koenig originally located on the fountain at the center of the Tobin Plaza. The Sphere was damaged in the September 11 attacks and was donated by AXA Insurance Company to the Interim Memorial created on March 11, 2002, in Battery Park by LMDC, the Port Authority, and the City of New York. The Interim Memorial is dedicated "to all whose lives were taken, and the many who gave their lives trying to save them at the World Trade Center in the attacks of September 11, 2001." On the first anniversary of the attacks, Mayor Michael Bloomberg dedicated an eternal flame at the Interim Memorial.

During the rescue and recovery period when New York City's Department of Design and Construction controlled the WTC Site, the materials were taken to Fresh Kills landfill and steel was taken to a steel recycling plant in New Jersey. The National Institute of Standards and Technology selected certain pieces of steel for testing to study factors leading to the collapse of the Towers.

A note on the cover of the Steel Data Collection Spreadsheet attached to FEMA's World Trade Center Building Performance Study indicates that: "As of May 2002, of the 156 steel pieces listed in the spread sheet, 41 are at the National Institute of Standards [and Technology], 19 were discarded after [samples] were taken, 45 are at the salvage yards, and the rest either were discarded after they were documented or were accidentally processed in the salvage operation before or after being documented."

During the recovery efforts numerous requests were made by museums and other organizations for materials from the WTC Site. These requests were directed to the New York City Office of Emergency Management (OEM) and OEM allowed some organizations to take some materials. It has been reported that artifacts are in the possession of the Smithsonian Institution, the Federal Bureau of Investigation (FBI), the New York City Police Department (NYPD), the Fire Department of New York (FDNY), the Museum of the City of New York, the New York City Police Museum, the New York City Fire Museum, the Staten Island Historical Society, the New York Historical Society and the New Jersey Historical Society. One round planter containing a living yew tree was salvaged from the WTC Site and is now located at the Governor's mansion in a nursery behind the house. A 60-ton piece of steel was given to the United States Navy and was melted down for the SS New York. At one point the Mayor's office was giving away two-foot sections of steel and some of this steel is at Mt. Manresa—a retreat house in Staten Island that housed out-of-town workers involved in the recovery efforts at Fresh Kills. In addition, a traveling exhibition from the NYSM titled "Recovery: The World Trade Center Recovery Operation at Fresh Kills" has about 50 rare photographs and 40 objects and is touring the country.

The New York State Museum in Albany has a number of artifacts from the WTC Site including the heavily damaged Engine 6 pumper, recovered NYPD and FDNY objects, architectural remains, several battered flags, a large steel column from floors 7-9 of Tower Two, a damaged 20-foot high, 10-ton steel column from floors 71-73 of Tower One, the steering wheel from a car, observation deck souvenirs, melted floppy discs, keys, a crushed payphone, a large collection of firearms from the U.S. Customs House (Six World Trade Center), destroyed street lampposts, fire hydrants, a destroyed elevator door, pieces of the airplanes that crashed into the Twin Towers including a portion of the wheel assembly from one of the planes, a piece of fuselage, and a steel beam with an embedded airplane piece.

The Port Authority has a large number of artifacts catalogued and stored in Hangar 17 at John F. Kennedy (JFK) Airport. They were retrieved from Fresh Kills landfill and the steel recycling yard in New Jersey, as well as the WTC Site. One of the objects is a 36-foot-by-4-foot steel column that was the last large piece of steel carried off the WTC Site. It was removed in the ceremony on May 30, 2002, marking the day following the recovery of the last human remains at the site. Hangar 17 also contains pieces of a 100-foot-tall by 100-foot-wide section of the lower facade of Tower One with its Gothic arches. The collection also includes a portion of the Tower One antenna, a turnstile from the WTC PATH Terminal, a motor from one of the Twin Towers giant elevators, a bicycle rack with seven abandoned bikes and a silver and blue helmet, and six crushed ladder trucks and fire engines.

WORLD TRADE CENTER TRANSPORTATION HUB
(WTC PATH TERMINAL AND PEDESTRIAN CONNECTIONS)
IN NEW YORK CITY, NEW YORK

WHEREAS, the Port Authority of New York and New Jersey ("PANYNJ") proposes to construct a World Trade Center Transportation Hub, consisting of a permanent WTC PATH Terminal and pedestrian connections ("the Project") at the World Trade Center ("WTC") Site, currently bounded by Church, Liberty, West, and Vesey Streets in Manhattan; and

WHEREAS, the previous WTC PATH Terminal facility was destroyed as the result of the terrorist attacks on September 11, 2001, and re-establishment and enhancement of the WTC PATH transportation facility is critical to the long term economic revitalization and growth of Lower Manhattan; and

WHEREAS, a temporary WTC PATH station was constructed by PANYNJ and has been operating since November 23, 2003; and

WHEREAS, PANYNJ is proposing to use funding assistance from the Federal Transit Administration ("FTA") to implement the Project, assistance that renders the Project a Federal undertaking subject to Section 106 of the National Historic Preservation Act ("Section 106"), 16 USC § 470; and

WHEREAS, FTA, as lead agency, in cooperation with PANYNJ, has prepared an Environmental Impact Statement ("EIS") in accordance with the National Environmental Policy Act ("NEPA") to evaluate the Project's potential environmental impacts and consider various project alternatives; and

WHEREAS, FTA has consulted with the New York State Historic Preservation Office ("SHPO") and the Advisory Council on Historic Preservation ("ACHP") about the Project in accordance with the Section 106 regulations (codified at 36 CFR Part 800); and

WHEREAS, FTA, in consultation with SHPO, has determined the Area of Potential Effect ("APE") for the Project as defined in 36 CFR 800.16(d), to be as depicted on the map presented as Exhibit A hereto, and have identified the properties listed in or eligible for inclusion in the National Register of Historic Places ("Historic Properties" and/or "Historic Resources") within that APE (pursuant to 36 CFR 800.4[b]-[d]), and has determined the effects of the Project on the identified Historic Properties in accordance with 36 CFR 800.5; and

WHEREAS, FTA has applied the Criteria of Adverse Effect (36 CFR 800.5[a][1]), in consultation with SHPO, and has determined that implementation of the Project will have an adverse effect on the following Historic Properties within the APE:

a. WTC Site (Tower Perimeter Column Remnants outlining the footprints of the North Tower and the South Tower and the footprints with Other Column Bases and Infrastructure, E Subway Entrance, East and West Slurry Walls, Steel Beams in Cross Form and Remnants of the Hudson Terminal and the H&M Railroad); and
b. Hudson River Bulkhead; and

WHEREAS, FTA has applied the Criteria of Adverse Effect (36 CFR 800.5[a][1]), in consultation with SHPO, and has determined that implementation of the Project may have an adverse effect on the following Historic Properties within the APE:

a. WTC Site: Vehicular Entrance Ramps, Cooling Water Pipes, Southern Projection, Tiebacks, PATH Tunnel Access, South Slurry Wall, Recovery and Construction Ramp, Hudson Tubes, Vehicular Access Ramp (connecting Barclay Street with 7 WTC), North Slurry Wall, 6 WTC, Vehicular Access Ramp to Barclay Street (under 7 WTC), and Restored NYCT No. 1/9 Subway Line;
b. Barclay-Vesey Building, 140 West Street;
c. Former East River Savings Bank, 26 Cortlandt Street;
d. Beard Building, 125 Cedar Street;
e. 114-118 Liberty Street; and
f. St. Paul's Chapel and Graveyard, Broadway and Fulton Street; and

WHEREAS, FTA finds, in consultation with SHPO and PANYNJ, that the Project may have adverse effects on archaeological resources yet to be identified within the APE in areas depicted in Exhibit B attached hereto; and

WHEREAS, FTA has applied the Criteria of Adverse Effect (36 CFR 800.5[a][1]), in consultation with SHPO, and has determined that implementation of the Project will result in no adverse effect on the following Historic Properties within the APE:

a. WTC Site (any elements not included in the foregoing two Whereas clauses);
b. Federal Office Building/U.S. Post Office, 90 Church Street;
c. St. Peter's Roman Catholic Church, 22 Barclay Street;
d. Former St. Peter's School;
e. 30 Vesey Street;
f. Old New York Evening Post Building, 20 Vesey Street;
g. New York County Lawyers' Association, 14 Vesey Street;
h. Astor Building, 217 Broadway;
i. Transportation Building, 225 Broadway;
j. African Burial Ground and the Commons Historic District, bounded by Duane Street, Park Row, Broadway and Center Street;

k. Former AT&T Company Building, 195 Broadway;
l. 21-23 Thames Street;
m. 90 West Street;
n. Fulton Street IRT Station;
o. Plaza and subway access from Vesey Street; and
p. United States Realty Building, 115 Broadway; and

WHEREAS, since early 2002, PANYNJ and the Lower Manhattan Development Corporation ("LMDC") have coordinated with New York State Department of Transportation ("NYSDOT"), FTA, the U.S. Department of Housing and Urban Development ("HUD"), and the Federal Highway Administration ("FHWA") with respect to historic and environmental analyses including Environmental Performance Commitments ("EPC's") (attached hereto as Exhibit C), coordinated Section 106 meetings prior to the execution of a Coordinated Determination of Eligibility ("DOE"), and the execution of a Coordinated DOE itself; and

WHEREAS, PANYNJ, LMDC, NYSDOT and New York Metropolitan Transportation Authority ("MTA") concurred to adhere to certain common commitments set forth in the EPC's, as part of the Environmental Analysis Framework ("EAF") (attached hereto as Exhibit D), that commit to the coordinated analysis of cumulative environmental impacts including Air Quality, Noise and Vibration, Cultural and Historic Resources, Access and Circulation, and Economic Effects; and

WHEREAS, coordinated Section 106 meetings occurred among PANYNJ, LMDC, NYSDOT, FTA, HUD, FHWA and SHPO, which, in addition to soliciting input from the Project's Consulting Parties, developed the framework for a Coordinated DOE; and

WHEREAS, a Coordinated DOE, in consultation with the Project's Consulting Parties, was finalized on March 31, 2004, and concluded that the WTC Site is eligible for inclusion in the National Register of Historic Places; and

WHEREAS, the Coordinated DOE of the WTC Site for the National Register identified elements that contribute to the WTC Site's historic significance; and

WHEREAS, based on the findings in the Coordinated DOE, the federal agencies proceeded with the planning and development of their separate projects under their jurisdiction. Where the Permanent WTC PATH Terminal Project and another project (the WTC Memorial and Redevelopment Plan, Fulton Street Transit Center, or the Route 9A Project) affect a particular element as identified in the DOE, PANYNJ and the appropriate sponsoring agency(s) will coordinate their respective projects such that the effects of the Project on these elements are fully addressed in consultation with SHPO and the Project's Consulting Parties; and

WHEREAS, PANYNJ, during project design, construction, system testing, and the first six months of full operation of the Project, will review and consider all construction plans for redevelopment of the WTC Site that may result in long-term or unanticipated adverse effects on the WTC Historic Property in order to avoid, minimize, or mitigate such effects on historic

properties that may result from multiple projects and their incremental cumulative impacts on the WTC Site as defined in 40 CFR 1508.7; and

WHEREAS, the United States Department of Transportation ("DOT") is evaluating project alternatives for the reconstruction of a half-mile section of Route 9A (West Street) along the west side of the WTC Site through FHWA; and is proposing construction of the Fulton Street Transit Center, which will have pedestrian connections to the Project through FTA; and has executed a Section 106 Amendment to the 1994 Programmatic Agreement dated October 13, 2004 and attached hereto in Exhibit E; and executed a Section 106 Programmatic Agreement dated September 24, 2004, respectively; and

WHEREAS, LMDC, as a recipient of community development block grant assistance from HUD, is responsible for the planning and execution of the WTC Memorial and Redevelopment Plan, that is the subject of a Programmatic Agreement among LMDC, SHPO and ACHP executed on April 22, 2004 and attached hereto as Exhibit F hereto; and

WHEREAS, these other projects associated with the WTC Site are subject to certain executed Section 106 Agreement documents(s) referenced above and this Memorandum of Agreement ("Agreement") is not intended to amend, modify and/or create additional requirements for those projects under their respective executed Section 106 Agreement document(s); and

WHEREAS, pursuant to that certain Programmatic Agreement, LMDC, in cooperation with PANYNJ, has prepared documentation ("Proposed Removal of Remnants from the Northwest Corner of the World Trade Center Site") of the Northwest Slab remnants located in the WTC Site and has identified the following resources to be removed from the WTC Site to Hangar 17 at John F. Kennedy International Airport ("Hangar 17"):

a. smoke-scarred column;
b. column with blistered paint;
c. wall section from Level B2 with locational sign;
d. day-glow handrails; and

WHEREAS, SHPO, on May 24, 2004, has concurred with the "Proposed Removal of Remnants from the Northwest Corner of the World Trade Center Site"; and

WHEREAS, LMDC and PANYNJ, recognized that certain other items were relevant to the WTC Site and shall preserve the wall section with heart and cross graffiti and two steel beams with the name "Levinson" stamped on them, from the Northwest Slab remnants from the WTC Site; and

WHEREAS, PANYNJ is the interim custodian of certain structural materials and other items (hereafter referred to as "off-site artifacts") removed from the WTC Site and the immediately surrounding area during the post-September 11, 2001 recovery effort and now located in Hangar 17 and other PANYNJ locations; and

WHEREAS, the Project's key goals and objectives include the following: Create a World-Class, Transportation Facility; Support the Redevelopment of Lower Manhattan; Provide for Improved

Pedestrian Connections; Provide for Advanced Security; Enhance Pre-September 11, 2001 PATH Operations; Support 10-Car PATH Trains in Order to Support Ridership Growth; Minimize Impacts to Temporary PATH Service during Construction; Minimize Impacts to the Local Environment during Construction; and Minimize Construction Cost and Duration; and

WHEREAS, of the different alternatives further evaluated and identified in the EIS, FTA and PANYNJ determined that one alternative is the optimal configuration; and

WHEREAS, FTA and PANYNJ evaluated three alternatives to be carried forward for further study in the Draft EIS, identified as a No Action Alternative, and two alternatives of the optimal configuration: a Terminal with Liberty Plaza Connection Alternative and a Terminal without Liberty Plaza Connection Alternative; and determined that the selected alternative for transit service between New Jersey and Lower Manhattan is the Terminal without Liberty Plaza Connection; and

WHEREAS, this Agreement was developed with appropriate public involvement (pursuant to 36 CFR 800.2[d] and 800.6[a]) both coordinated with the scoping, public review and public hearings conducted to comply with NEPA and its implementing regulations and through public meetings specifically conducted to comply with NHPA and its implementing regulations; and in consultation with the SHPO, ACHP and (pursuant to 36 CFR 800.2[d] and 800.6[a]) more than 70 invited Consulting Parties (identified in Exhibit G hereto); and

WHEREAS, National Park Service ("NPS") may have an ongoing interest in the WTC Site and will be recognized as a Consulting Party in the implementation of this Agreement, and will be provided appropriate documentation to assist in any subsequent evaluation of the WTC Site; and

WHEREAS, the public was provided the opportunity to comment on the Project and the following Project documents, and the public will hereafter be provided with further opportunities to comment on the Project as stipulated further in this Agreement:

1. Scoping document for the preparation of an EIS for the Project pursuant to NEPA and its implementing regulations;
2. Draft EIS for the Project, dated May 2004, prepared pursuant to NEPA;
3. Draft Finding of Effects, distributed June 3, 2004, prepared pursuant to NHPA; and

WHEREAS, on June 4, 2004, by copy of the Draft EIS, the following Native American Tribes have been invited, through the NEPA process, to comment on the Project: the Shinnecock Nation; the Cayuga Nation; the Tuscarora Nation; the Saint Regis Band of Mohawk Indians; the Delaware Nation; the Poospatuck Nation; the Onondaga Indian Nation; the Oneida Indian Nation; the Tonawanda Band of Seneca; and the Stockbridge-Munsee Band of Mohicans. To date, FTA and PANYNJ have received comment from the Shinnecock Nation. An opportunity for further comment will continue as per provisions stated in Stipulation X; and

WHEREAS, the following Native American Tribes have been invited to participate in the Section 106 review: Cayuga Nation, Delaware Nation, Shinnecock Nation Cultural Center and Museum, St. Regis Band of Mohawk Indians, Stockbridge-Munsee Band of Mohicans. To date,

FTA and PANYNJ have received comments from the Shinnecock Nation. An opportunity for further comment will continue as per provisions stated in Stipulation X; and

WHEREAS, in response to Executive Order 133 for the State of New York signed on November 22, 2004, the Lower Manhattan Construction Command Center ("LMCCC") was established to ensure that adverse effects at Lower Manhattan Recovery Projects are minimized, coordinate the work of the participants, institute and implement construction coordination protocols and requirements, and mediate conflicts in schedules.

NOW, THEREFORE, FTA, SHPO, ACHP and PANYNJ, as the signatory parties to this agreement, agree that the Project will be implemented in accordance with the following stipulations to ensure that the effects of the Project on Historic Properties are taken into account.

STIPULATIONS

FTA, as the Federal lead agency, remains responsible for the implementation of the terms of this Agreement and will require, as a condition of any approval of Federal funding for the Project, adherence to the stipulations set forth herein. PANYNJ, the project sponsor, will have the lead in the implementation of each stipulation unless otherwise noted in the stipulation.

I. WORLD TRADE CENTER SITE

Because the WTC Site is located in the APE of the WTC Memorial and Redevelopment Plan as well as in the APE for the Project, PANYNJ shall coordinate treatment of the WTC Site with LMDC.

A. DOCUMENTATION

1. As a measure to address adverse effects to the WTC Site, PANYNJ, prior to removal or alteration of any historic features of the WTC Site in connection with this Project, shall ensure that the WTC Site and its historic features are documented to Level II standards of the Historic American Buildings Survey/Historic American Engineering Record ("HABS/HAER"). This documentation shall consist of large format black-and-white photographs of the Site and historic features, as they currently exist.

   The construction fill on the footprints was temporarily removed for the purposes of documentation stipulated by this Agreement, and will be replaced with clean rounded gravel after the documentation in order to protect the footprints and column remnants from ongoing construction. Large-format photographic reproduction of selected drawings of current conditions and of pre-9/11 conditions, and a written history will be prepared and a description of the Site and historic features utilizing information previously generated for the Coordinated DOE for the WTC Site and the Project's EIS. HABS/HAER documentation generated by PANYNJ will be presented as a single submission to SHPO.

2. PANYNJ shall consult with SHPO and HABS/HAER to determine whether particular features warrant measured drawings; any such drawings shall be prepared by an individual

with demonstrated expertise in the preparation of measured drawings to HABS/HAER standards.

3. PANYNJ shall deposit the completed documentation in the following repositories unless otherwise determined by SHPO: (a) New York Historical Society; (b) New York City Public Library; (c) HABS/HAER; and (d) two copies to SHPO with one set to be forwarded to the New York State Archives. The large-format photographs prepared to HABS/HAER standards shall consist of the views itemized on the Schedule of Photographs appended hereto as Exhibit H. One set of the completed documentation will be presented to the WTC Memorial Center.

B. PERIMETER COLUMN REMNANTS OUTLINING NORTH TOWER AND SOUTH TOWER FOOTPRINTS AND THE TOWER FOOTPRINT AREAS AFFECTED

1. In the design and construction of the Project, PANYNJ shall to the maximum extent feasible, preserve in place 84 column base remnants in the North Tower and 39 column base remnants in the South Tower at the existing floor at elevation 242 (58 feet below Sea Level) that outline the footprints of the former Twin Towers at the WTC Site and are not located in the PATH right-of-way.

2. While striving to preserve in place the 84 column base remnants in the North Tower and the 39 column base remnants in the South Tower, up to a total of 16 column bases in the North Tower and up to a total of 3 column bases in the South Tower have the potential to be temporarily or permanently removed. If they are to be removed, they are to be removed as follows:

   a. *Platform D.* Every effort will be made to avoid removing any column bases, however, up to 5 column bases in the North Tower and up to 3 column bases in the South Tower could be temporarily or permanently removed to construct Platform D. The design of Platform D in the northeast corner area of the North Tower has been modified to move the vertical circulation element to the north and west on the Platform allowing the corner of the North Tower to be symbolically represented in the finish materials on the Platform. A minimum of 5 to a maximum of 7 column bases of the east column line of the North Tower will be visible from Platform D. The viewing area will consist of a glass wall tilted inward from the Platform combined with a mirrored wall along the west wall enabling viewing of the column bases from this area of the Platform. Appropriate signage, graphics, and lighting will complete the viewing area.

   b. *Platforms B, C, and D.* The locations of column remnants of the South Tower that may be removed or permanently obscured by the Project platforms shall be symbolically represented on these platforms through architectural treatments that will define and differentiate the portions of the infrastructure that are within the Tower footprint areas. These treatments may include color differentiation, texture differentiation, symbolic representation of Tower perimeter column remnants and/or an emblematic marker designating the location of the Historic Resource.

c. *Project Foundation.* Up to 4 column bases in the North Tower could be temporarily removed by work to install other Project structures and infrastructure. Of the 4 column bases that could be affected by the Project foundation, those column bases that remain in situ undisturbed or are temporarily removed and returned to their original locations will be accessible following the completion of these foundations.

3. Removing column bases, on either a temporary or permanent basis, will be considered only after practical engineering design options pursuant to Stipulations I. B. 2a and 2b, to preserve column bases in place have been exhausted. Column bases that are removed will be returned to their original locations if practical engineering design permits. Permanent removal of column bases will only take place as a last resort, and these column bases will be removed to Hangar 17 pursuant to Stipulation I. H.

4. The proposed east-west pedestrian corridor shall be designed and built in a manner that avoids the column remnants projecting above the concrete slab that outline the north perimeter of the North Tower and place this corridor at least 5 feet outside the North Tower footprint as measured from the center line of each projecting column base to the face of the nearest structural support wall.

5. The temporary PATH track (in addition to the existing 5 tracks) and associated ballast that will be installed on a temporary basis during construction of the Project tracks and platforms shall be removed upon completion of the permanent tracks and platforms to re-expose the North Tower and South Tower perimeter column remnants and portions of the North Tower and South Tower footprints that may be covered by the temporary track and ballast.

6. The total extent of the North Tower footprint at the lowest level, at approximately elevation 242 (58 feet below Sea Level) to be permanently occupied by any portion of the Project will be approximately 1,600 square feet and will not exceed 4% of the North Tower footprint area. The total extent of the South Tower footprint at the lowest level, at approximately elevation 242 (58 feet below Sea Level) to be permanently occupied by any portion of the Project will be approximately 21,615 square feet currently occupied by the WTC PATH facility, plus an additional 2,000 square feet required by the Project, and will not exceed 53% of the South Tower footprint area.

7. The construction fill on the footprints has been temporarily removed for the purposes of documentation of the footprints pursuant to Stipulation I.A. of this Agreement, and will be replaced with clean rounded gravel as required after the documentation in order to protect the footprints and column remnants from ongoing construction. Further treatments may be specified in the Resource Protection Plan.

8. Where treatments are set forth in this Stipulation under I. B. 2, PANYNJ shall follow this process:

   a. Design plans for the treatments will be developed in consultation with the SHPO and submitted at the preliminary (35%) and pre-final (75%) completion stages for SHPO comment. NPS and Consulting Parties will be given the opportunity to comment on the treatment design plans.

b. Design plans will be made available, subject to Stipulation IX.D., to the Consulting Parties and the public via the PANYNJ website at www.PANYNJ.gov/pathrestoration (Project website). The Consulting Parties will be informed of the availability of the plans by electronic notification as the plans are posted on the Project website and the Consulting Parties shall have 21 calendar days to comment on the plans. PANYNJ will provide paper copies of such plans to Consulting Parties upon request.

c. The review of the plans shall focus on the architectural treatments defining and differentiating the portions of the Project within the Tower footprint areas.

d. If SHPO makes substantive comments during the pre-final design review, SHPO may request the opportunity to concur on the final design.

e. SHPO will respond within 30 calendar days or earlier to the design plans at each stage of completion as described above.

f. Prior to approval of submitted plans and specifications, PANYNJ will consider and respond to all comments received from SHPO and Consulting Parties within the specified comments period. If SHPO does not respond within the comment period, PANYNJ may assume that SHPO concurs with the submitted plans and specifications.

C. E SUBWAY ENTRANCE

1. The new pedestrian connection between the Terminal and the MTA/NYCT E Subway shall be designed to incorporate the existing E Subway entrance, in its current location, in a manner that retains existing materials and features of this entrance, including, but not limited to, the handrails, travertine flooring, including the existing steps and doors separating the E train from the pedestrian connection, and overhead signage, to the extent possible and consistent with current building codes and Americans with Disabilities Act requirements. This design will include, at a minimum, a plaque identifying the historic features of the E subway entrance.

a. Design plans for treatments will be developed in consultation with the SHPO and submitted at the preliminary (35%) and pre-final (75%) completion stages for SHPO comment. NPS and Consulting Parties will be given the opportunity to comment on the treatment design plans.

b. Design plans will be made available to the Consulting Parties and the public via the Project website. The Consulting Parties will be informed of the availability of the plans by electronic notification as the plans are posted on the Project website and the Consulting Parties shall have 21 calendar days to comment on the plans. PANYNJ will provide paper copies of such design plans to Consulting Parties upon request.

c. The review of the plans shall focus on the treatment of the existing E Subway entrance.

d. If SHPO makes substantive comments during the pre-final design review, SHPO may request the opportunity to concur on the final design.

e. SHPO will respond within 30 calendar days or earlier to the design plans at each stage of completion as described above.

f. Prior to approval of submitted plans and specifications, PANYNJ will consider and respond to all comments received from SHPO and Consulting Parties within the specified comments period. If SHPO does not respond within the comment period, PANYNJ may assume that SHPO concurs with the submitted plans and specifications.

2. If during construction of the new pedestrian connection between the Terminal and the E Subway, it is determined that the existing E Subway entrance doors need to be removed, then they will be removed in accordance with Stipulation VI below.

D. PENETRATION OF EAST AND WEST SLURRY WALLS FOR THE PROJECT

1. The design for the Project shall provide visibility from within the Terminal to a portion of the East or West Slurry Wall if the following criteria are met: the condition of the slurry wall evokes the image now understood to represent the historic nature of the wall (e.g. Tiebacks are part of the area to be exposed, Tiebacks project beyond the re-stabilized slurry wall); the exposure provided would enable a view of the slurry wall which is clear, recognizable, and respectful of the slurry wall; and the exposure would not pose a safety hazard to the public from exposed finishes of the wall or its components. The design for the East-West Pedestrian Connector shall include a location from which the members of the public using the Connector may, at a minimum, view a plaque and photograph of the West Slurry Wall.

a. Design plans for treatments will be developed in consultation with the SHPO and submitted at the preliminary (35%) and pre-final (75%) completion stages for SHPO comment. NPS and Consulting Parties will be given the opportunity to comment on the treatment design plans.

b. Design plans will be made available to the Consulting Parties and public via the Project website. The Consulting Parties will be informed of the availability of the plans by electronic notification as the plans are posted on the Project website and the Consulting Parties shall have 21 calendar days to comment on the plans. PANYNJ will provide paper copies of such design plans to Consulting Parties upon request.

c. The review of the plans shall focus on the slurry wall mitigation.

d. If SHPO makes substantive comments during the pre-final design review, SHPO may request the opportunity to concur on the final design.

e. SHPO will respond within 30 calendar days or earlier to the design plans at each stage of completion as described above.

f. Prior to approval of submitted plans and specifications, PANYNJ will consider and respond to all comments received from SHPO and Consulting Parties within the specified comments period. If SHPO does not respond within the comment period, PANYNJ may assume that SHPO concurs with the submitted plans and specifications.

E. STEEL BEAMS IN CROSS FORM

PANYNJ shall relocate the steel column and crossbeam mounted on a concrete pedestal and currently situated within the WTC Site near Church Street to Hangar 17 or an alternate location in accordance with Stipulation VI below, where the object will remain in the custody and control of PANYNJ as are other off-site artifacts in Hangar 17 from the WTC Site, pending final disposition of these artifacts in accordance with the rights of the respective owners thereof.

F. RESOURCE PROTECTION PLAN FOR CONSTRUCTION AT WTC SITE

1. To protect historic elements of the WTC Site that are to remain in situ from inadvertent damage during construction activities of this Project within the WTC Site, PANYNJ, in consultation with SHPO and in coordination with LMDC and with (as appropriate) those with certain property interests in the WTC Site, shall develop a WTC Resource Protection Plan ("WTCRPP") for the Project after the Record of Decision for the Project.

2. The WTCRPP will describe in detail the construction procedures of the Project related to Historic Properties and the construction procedures associated with other projects under construction in the vicinity of those Historic Properties. It will also provide, with respect to the Project, for the inspecting and reporting of existing conditions at these historic elements; establish protection procedures; establish a monitoring program; establish and monitor construction methods; and establish methods and materials to be used for any repairs. A historic architect who meets the Secretary of the Interior's professional qualifications standards (48 F.R. 44716) in historic preservation will be part of the design/construction team for the Project and will have the opportunity to review design drawings and specifications for the Project prior to construction in order to prevent damage to Historic Resources.

3. The WTCRPP will empower the historic architect, in consultation with the Chief Engineer of PANYNJ ("Engineer") or the Engineer's designee, to issue "stop work" orders with respect to this Project to prevent any unanticipated damage to Historic Properties, and any recommencement of work shall only be permitted at such time that the Engineer and historic architect determine that the appropriate modifications have been made to the construction technique to assure that no damage will occur to Historic Properties.

4. PANYNJ shall furnish copies of the WTCRPP to SHPO, ACHP, NPS and Consulting Parties for review and comment on the WTCRPP with respect to the Project. NPS and Consulting Parties shall have 21 calendar days in which to comment on the WTCRPP with respect to the Project. SHPO and ACHP shall have 30 calendar days in which to review and comment on the WTCRPP with respect to the Project. Should SHPO and ACHP fail to respond within the 30 calendar day period, PANYNJ may assume

concurrence with the WTCRPP. PANYNJ shall consider all comments on the WTCRPP with respect to the Project received within this review period in preparing the final WTCRPP. The WTCRPP for the Project shall be in place prior to the commencement of construction of the WTC PATH Terminal.

G. CUMULATIVE EFFECTS

1. PANYNJ shall follow the process described below to address previously unanticipated cumulative adverse effects on the Historic Resources on the WTC Site during Project design, implementation, and testing, and the first six months of full operation of the Project that are caused in part by the permanent WTC PATH Terminal project together with other WTC Site project activities that, when considered along with existing conditions as well as reasonably foreseeable future conditions may cause irreversible or long-term adverse effects on qualifying characteristics of the WTC Site that were to be preserved or protected based upon the terms of this Agreement or other executed Section 106 Agreement document(s) associated with the WTC Site.

2. PANYNJ shall request all agencies that are constructing projects within the WTC Site to submit preliminary and pre-final documents to the PANYNJ to allow coordination of the Project activities with such other work and to permit the PANYNJ's assessment of the Project to include the potential for cumulative adverse effects on the WTC Site per I.G.1.

3. PANYNJ and its historic preservation consultant, will consult with SHPO and Lower Manhattan Emergency Preservation Fund (consisting of the following coalition of five preservation groups: Municipal Art Society, National Trust for Historic Preservation, New York Landmarks Conservancy, Preservation League of New York State, and the World Monuments Fund) in assessing whether there is a potential for cumulative adverse effects of the Project and other WTC Site projects per I.G.1.

4. If PANYNJ and SHPO agree that Project plans or completed activities have resulted in or are likely to result in cumulative adverse effects on the WTC Site per I.G.1 of this Agreement, then PANYNJ shall consider measures with respect to the Project to mitigate or minimize such effects, including technical or financial measures for the protection, rehabilitation, or repair and Project design modifications. Disagreements between the PANYNJ and SHPO, including those related to effects findings, will be resolved pursuant to Stipulation X.

5. PANYNJ shall make all appropriate PANYNJ-generated and prepared documentation related to the Project for Section 106 purposes and utilized in consideration of cumulative adverse effects in I.G.4 available to the Consulting Parties and NPS via the Project website. Consulting Parties will be notified of the documentation posting to the Project website via electronic notification. The Consulting Parties and NPS shall have 21 calendar days to comment on the documentation. PANYNJ will provide paper copies of such documentation to Consulting Parties upon request. SHPO, ACHP, and WTC project agencies will respond within 30 calendar days of receipt of all required documentation. Should SHPO, ACHP, or any project agency, fail to respond within 30 calendar days

after receipt of all documentation, it shall be assumed that they have no comments on the proposed action, if any, to minimize or mitigate cumulative adverse effects.

6. The review of the documentation by all parties per I.G.5 shall focus on the historic elements of the WTC Site Historic Property that may be affected by the Project relative to the potential for cumulative adverse effects.

7. PANYNJ, in coordination with other project agencies as appropriate, and SHPO will consider and respond to comments on the Project and its potential for cumulative adverse effects on the WTC Site Historic Property from Consulting Parties and attempt to resolve any concerns about how PANYNJ intends to address cumulative adverse effects per I.G.1 of this Agreement. If PANYNJ, in consultation with SHPO are unable to reach a resolution with the Consulting Parties who have commented pursuant to I.G.5. regarding an adverse effect with respect to the Project and its potential for cumulative adverse effects on the WTC Site Historic Property, the PANYNJ will notify the FTA, and as appropriate, consult with the ACHP, in accordance with Stipulation X.

8. PANYNJ shall comply with other agreement documents referenced in this Agreement and the EIS related to archaeological resource treatment, noise and vibration in the WTC Construction Protection Plan for the Barclay-Vesey Building, Former East River Savings Bank, Beard Building, 114-118 Liberty Street, and St. Paul's Chapel and Graveyard and the WTCRPP when considering cumulative adverse effects on the Historic Properties both on and off of the WTC Site that may result from the Project and other related, approved project undertakings.

H. OFF-SITE ARTIFACTS

PANYNJ shall safeguard all artifacts from the WTC Site that are now or may come to be in its custody and control, pending final disposition of such artifacts in accordance with the rights of the respective owners thereof. This obligation will be fulfilled in consultation with LMDC as specified in Stipulation 4(a)(3) and Stipulation 4(b) of the April 22, 2004 Programmatic Agreement among the ACHP, LMDC and SHPO for the WTC Memorial and Redevelopment Plan. A complete inventory listing of all off-site WTC artifacts in PANYNJ's custody and control as of August 2004 shall be available to the Consulting Parties upon written request to PANYNJ. Additional artifacts may come into the custody and control of PANYNJ, and the listing of these artifacts will be incorporated into the semiannual report to be distributed to the signatory parties and Consulting Parties.

II. HUDSON RIVER BULKHEAD

A. COORDINATION

Because the Hudson River Bulkhead is located in the APE of the proposed reconstruction of West Street (Route 9A) as well as in the APE for the Project, PANYNJ shall coordinate treatment of this Historic Property with FHWA and NYSDOT.

B. LOCATION AND IDENTIFICATION

In consultation with the SHPO, and, as appropriate with NYSDOT, PANYNJ shall develop and implement a plan to locate and identify intact portions of the Hudson River Bulkhead that will be affected by construction of the East-West Pedestrian Connector.

C. TREATMENT

In the event that intact portions of the Hudson River Bulkhead are identified as a result of execution of Stipulation II.B, PANYNJ shall, in consultation with the SHPO and NYSDOT, prepare a treatment plan for those portions of the Hudson River Bulkhead to be affected by the Project.

D. TREATMENT PLAN

1. Design plans for treatments will be developed in consultation with the SHPO and submitted for SHPO comment at the preliminary (35%) and pre-final (75%) completion stages. NPS and Consulting Parties will also be given the opportunity to comment.

2. Design plans will be made available to the Consulting Parties and the public via the Project website. The Consulting Parties will be informed of the availability of the plans by electronic notification as the plans are posted on the Project website and the Consulting Parties shall have 21 calendar days to comment on the plans. PANYNJ will provide paper copies of such design plans to Consulting Parties upon request.

3. The review of the plans shall focus on the Hudson River Bulkhead mitigation.

4. If SHPO makes substantive comments during the pre-final design review, SHPO may request the opportunity to concur on the final design.

5. SHPO will respond within 30 calendar days or earlier to the design plans at each stage of completion as described above. If SHPO does not respond within the comment period, PANYNJ may assume that SHPO concurs with the submitted plan.

6. PANYNJ will consider and respond to all comments received from SHPO within the specified comment period and Consulting Parties prior to approval of submitted plans and specifications.

III. BARCLAY-VESEY BUILDING, FORMER EAST RIVER SAVINGS BANK, BEARD BUILDING, 114-118 LIBERTY STREET, AND ST. PAUL'S CHAPEL AND GRAVEYARD

A. COORDINATION

Because the Historic Properties listed in the title of this Stipulation are located in the APE of the WTC Memorial and Redevelopment Plan as well as in the APE for the Project, PANYNJ shall coordinate treatment of them with LMDC.

The Former East River Savings Bank and St. Paul's Chapel and Graveyard are also located within the APE of the Fulton Street Transit Center. PANYNJ shall therefore coordinate treatment of these Historic Properties with MTA/NYCT.

B. CONSTRUCTION PROTECTION PLAN FOR THE BARCLAY-VESEY BUILDING, FORMER EAST RIVER SAVINGS BANK, BEARD BUILDING, 114-118 LIBERTY STREET, AND ST. PAUL'S CHAPEL AND GRAVEYARD

1. To protect these buildings from project-generated construction vibration from the Project, PANYNJ, in consultation with SHPO and in coordination with LMDC and, as appropriate, with MTA/NYCT, shall develop a Construction Protection Plan ("CPP") for the Project. The CPP will set forth measures for protection and avoidance of structural and architectural damage from the Project for these Historic Properties.

2. The CPP will be based on the requirements laid out in the "New York City Department of Buildings Technical Policy and Procedure Notice ("PPN") #10/88" regarding procedures for the avoidance of damage to historic structures resulting from adjacent construction. The PPN defines an adjacent historic structure as being contiguous to or within a lateral distance of 90 feet from a lot under development or alteration.

3. The CPP will describe in detail the construction procedures of the Project related to Historic Properties and the construction procedures associated with other projects under construction in the vicinity of each of these Historic Properties. With respect to the Project, the CPP will also provide for the inspecting and reporting of existing conditions at these properties; establishing protection procedures; establishing a monitoring program to measure vertical and lateral movement and vibration; establishing and monitoring construction methods to limit vibrations; and establishing methods and materials to be used for any repairs. The CPP shall also specify the implementation of special vibration protection measures to protect these Historic Properties from increased vibration levels associated with construction activities of the Project. For these extremely fragile buildings, these vibration protection measures for the Project shall reduce vibration levels to levels below FTA's vibration damage threshold criterion of 0.12 in/sec (approx 95 VdB). The CPP will provide for a historic architect meeting the Secretary of the Interior's professional qualifications standards (48 F.R. 44716) to work with an engineer with demonstrated comparable expertise in working with historic buildings to supervise implementation of the CPP.

4. The CPP will empower the historic architect, in consultation with the Chief Engineer of PANYNJ ("Engineer") or the Engineer's designee, to issue "stop work" orders with respect to this Project to prevent any unanticipated damage to Historic Properties, and any recommencement of work shall only be permitted at such time that the Engineer and historic architect determine that the appropriate modifications have been made to the construction technique to assure that no damage will occur to Historic Properties.

5. PANYNJ shall furnish copies of the CPP to SHPO, ACHP and Consulting Parties for review and comment with respect to the Project. The Consulting Parties will have 21 calendar days in which to comment on the CPP with respect to the Project. SHPO and ACHP shall respond

within 30 calendar days of the request for review and comment on the CPP with respect to the Project. Should SHPO and ACHP fail to respond within the 30 calendar day period, the PANYNJ may assume concurrence with the CPP. PANYNJ shall consider all comments received with respect to the Project within this review period in preparing the final CPP. The CPP for the Project shall be in place prior to the commencement of construction of the WTC PATH Terminal that could affect fragile buildings in the APE.

IV. ARCHAEOLOGICAL RESOURCES

A. COORDINATION

The areas of potential historic archaeological sensitivity in the Project's APE are former Lots 8-17 on former Block 85 (south side of Vesey Street between Greenwich and Church Streets) and former Lots 5, 6 and 10 on former Block 60 (north side of Liberty Street between Greenwich and Church Streets). Because these areas of potential historic archaeological sensitivity are located in the APE of the WTC Memorial and Redevelopment Plan as well as in the APE for the Project, PANYNJ shall coordinate fulfillment of this Stipulation with SHPO and LMDC. The locations of these archaeologically sensitive areas are shown on the map appended hereto as Exhibit B.

B. LOCATION, IDENTIFICATION, AND EVALUATION

Prior to any Project-related subsurface disturbance at any of the locations that have been determined to be sensitive for historic archaeological resources, PANYNJ shall, in consultation with the SHPO, and LMDC as appropriate, locate, identify, and evaluate the National Register eligibility of any archaeological resources at these locations in accordance with 36 CFR 800.4.

C. TREATMENT PLAN FOR ARCHAEOLOGICAL RESOURCES

1. In the event that FTA, in consultation with SHPO, determines that National Register-eligible archaeological resources will be adversely affected by construction of the Project, PANYNJ shall, in consultation with FTA, SHPO, and LMDC as appropriate, and the Consulting Parties, develop and implement a Treatment Plan for the Project. The Treatment Plan will balance Project (engineering, environmental and economic) and historic preservation concerns while addressing specific research questions. The Treatment Plan and documentation will adhere to the standards established by the Secretary of the Interior's Standards and Guidelines for Archaeology and Historic Preservation (48 FR 44716), including the standards therein for professional qualifications

2. The Treatment Plan will be made available to the Consulting Parties via the Project website. The Consulting Parties will be informed of the availability of the plan by electronic notification as the plan is posted on the Project website and the Consulting Parties shall have 21 calendar days to comment on the plans.

3. SHPO shall have 30 calendar days in which to comment on the Treatment Plan. If SHPO does not respond within the comment period, PANYNJ may assume that SHPO concurs with the Treatment Plan.

4. The Treatment Plan described above will be posted on the Project website. PANYNJ will provide paper copies of the Treatment Plan to the Consulting Parties upon request.

V. UNANTICIPATED DISCOVERIES OF ARCHAEOLOGICAL RESOURCES AND UNANTICIPATED EFFECTS ON HISTORIC RESOURCES

A. UNANTICIPATED DISCOVERY OF ARCHAEOLOGICAL RESOURCES

In the event that unanticipated archaeological deposits or features are encountered during the construction of the Project, PANYNJ shall immediately implement the procedures described in Exhibit I hereto.

B. UNANTICIPATED EFFECTS ON HISTORIC RESOURCES

In the event that PANYNJ determines that construction of the Project will affect or has affected a Historic Resource in an unanticipated manner other than those identified in Stipulation I.F., PANYNJ shall stop Project construction in the vicinity of the affected resource and shall take reasonable measures with respect to the Project, to avoid harm to the resource until it has consulted with the SHPO to develop a treatment or mitigation plan with respect to the Project. PANYNJ may perform additional measures to secure the job site if it determines that unfinished work in the vicinity of the affected resource will cause major safety or security concerns. Upon notification, SHPO will have 14 calendar days to review and comment on the treatment or mitigation plans. Should SHPO fail to respond within the 14 calendar day period, the PANYNJ may assume concurrence with the treatment plan or mitigation plans. If PANYNJ and SHPO cannot agree on a treatment or mitigation plan, the dispute resolution process set forth in Stipulation X below will be followed.

VI. TEMPORARY RELOCATION OF HISTORIC ELEMENTS OF THE WTC SITE

TEMPORARY RELOCATION OF HISTORIC ELEMENTS

If PANYNJ determines that historic elements (potentially anticipated to be Tower Perimeter Column Remnants and E Subway Entrance of the WTC Site) must be temporarily relocated in order to protect them from damage during construction of the Project, PANYNJ shall:

1. Prior to relocation, notify SHPO and Consulting Parties of the elements requiring temporary relocation.

2. Prior to relocation, consult with their design/construction team historic architect who meets the Secretary of the Interior's professional qualifications standards (48 FR 44716) and in consultation with SHPO, develop a plan for (a) removing the elements in a manner that maintains their integrity of materials and workmanship; (b) safeguarding the removed elements while relocated to Hangar 17 or any other agreed upon location; (c) returning the elements to the WTC Site, based on criteria to be developed by PANYNJ and reviewed by ACHP and SHPO. Elements not returned to the WTC Site will remain in the control and custody of PANYNJ in Hangar 17 or other PANYNJ sites until the final disposition of all

artifacts in PANYNJ's custody has been determined. This determination of custody will take place outside the parameters of this Project.

3. Prior to relocation, SHPO will respond within 30 calendar days or earlier to the plan for temporary relocation and safeguarding of the element or elements. Should SHPO fail to respond within the 30 calendar day period, PANYNJ may assume concurrence with the relocation plan.

4. Prior to the relocation, PANYNJ will consider those comments provided within the specified time frame in finalizing the plans. PANYNJ shall implement the final plan.

5. PANYNJ shall notify SHPO and Consulting Parties in writing when temporarily removed elements have been returned to the WTC Site.

6. The Consulting Parties will be provided updates regarding the above 5 items through electronic notification and the Project website.

VII. MONITORING

SHPO may monitor activities carried out pursuant to this Agreement at its discretion. PANYNJ will cooperate with SHPO with respect to such monitoring activities.

VIII. ADDITIONAL COORDINATION REGARDING NEWLY AFFECTED HISTORIC PROPERTIES

1. If construction activities associated with the Project may affect Historic Properties other than those whose treatments will be coordinated with other agencies as set forth in Stipulations I, II and III of this Agreement, PANYNJ shall determine whether the newly affected Historic Property is within the APE of the WTC Memorial and Redevelopment Plan, the reconstruction of West Street, and/or the Fulton Street Transit Center. If the newly affected Historic Property is not also within the APE of one or more of these projects, PANYNJ will proceed as set forth in Stipulation V.B.

2. If PANYNJ determines that the newly affected Historic Property is also within the APE of one or more of these projects, PANYNJ shall include this information in any notification to the SHPO under Stipulation V.B and shall invite the relevant project sponsor(s) and respective lead agency to participate in consultation with SHPO to determine the appropriate course of action.

IX. ADMINISTRATION OF THIS AGREEMENT

A. COOPERATION

During implementation of this Agreement, each signatory party agrees to cooperate with the other signatory parties to facilitate the satisfaction of their respective obligations under this Agreement. The signatory parties each agree to work in good faith with the other signatory parties to meet their respective obligations in a timely manner.

B. SUBMITTALS TO SHPO

Unless otherwise specified in this Agreement, PANYNJ shall submit to SHPO all documents, drawings or other materials for which PANYNJ requests review, comment or concurrence.

C. SEMIANNUAL STATUS REPORTING

On or before January 31st and June 30th of each year and commencing on January 31, 2006, until the terms of this Agreement have been fulfilled, PANYNJ shall prepare and provide a semiannual report addressing the following topics:

- Progress in completing Stipulations I through V;
- Any unexpected issues encountered during the preceding six months; and
- Any changes that PANYNJ believes should be made in implementation of this Agreement.

PANYNJ shall make this report available to the signatory parties and Consulting Parties, and will invite Consulting Parties to provide comments to PANYNJ. PANYNJ will respond to comments received and, as appropriate, will provide the signatory parties with how PANYNJ responded to comments and notify the signatory parties if they need to further consider any comments. Any signatory party may request a meeting on the report. The report will also be posted on the Project website.

D. DOCUMENTATION

Notwithstanding any other provision in this Agreement, all documentation to be provided to the signatory parties, Consulting Parties, and the Public shall relate to the historic aspects of the Project as set forth in this Agreement subject to appropriate considerations, such as security concerns.

X. DISPUTE RESOLUTION

A. OBJECTIONS TO PLANS OR REPORTS BY SIGNATORY PARTIES

In the event any signatory party to this Agreement objects to any plan or report presented for the Project pursuant to this Agreement within 30 calendar days of its receipt, or within such other time frame specified in this Agreement, PANYNJ will consult further with the objecting signatory party to seek resolution. If PANYNJ is unable to reach resolution with respect to the Project, it will notify FTA, which in turn will consult with the objecting party to seek resolution with respect to the Project. If FTA determines that the objection cannot be resolved, FTA will invite the ACHP to review all Project documentation relevant to the dispute, including FTA's proposed resolution to an objection. ACHP will provide its comments to FTA within 30 calendar days. FTA will take these comments into account in reaching a final decision concerning the dispute.

Any recommendation or comment by the ACHP will pertain only to the subject of the dispute. The responsibility of the signatory parties to implement all actions pursuant to this Agreement that are not subject to the dispute will remain unchanged.

B. CONSULTING PARTY COMMENTS AND DISPUTE RESOLUTION

1. If PANYNJ receives written objections from any Consulting Party with respect to the Project regarding the treatment of Historic Properties, or on the design of the new structure or measures taken to implement the terms of this Agreement within 30 days of electronic notification of posting of plans, designs, or measures on the Project website, PANYNJ will consult with the objector regarding such objections.

2. PANYNJ shall consult with the objecting Consulting Party within 30 calendar days after receipt of written comments. If PANYNJ and the Consulting Party cannot resolve the matter with respect to the Project, PANYNJ shall notify SHPO and provide copies of the objection. SHPO, as appropriate, shall advise PANYNJ of measures, if any, that could resolve the matter.

3. If PANYNJ in consultation with SHPO cannot resolve the matter with respect to the Project, and PANYNJ and SHPO consider the issue of sufficient importance, PANYNJ and SHPO shall proceed as set forth in Stipulation X.A. above.

XI. AMENDMENT AND TERMINATION

A. AMENDMENT

Notwithstanding any other provision in this Agreement, any signatory party to this Agreement may request that it be amended, whereupon the signatory parties will consult to consider such amendment. PANYNJ will facilitate such consultation within 30 calendar days of such request. Any amendment must be in writing and signed by FTA, ACHP, SHPO and PANYNJ to be effective. The appropriate contacts for the signatory parties are provided in Exhibit J hereto.

B. TERMINATION

This agreement will terminate upon full completion of Project construction and after the first six months of full operation of the Project, or at such time as PANYNJ notifies the other parties in writing that the Project has been terminated.

This agreement may be terminated at the request of any of the signatory parties to this Agreement within 30 calendar days of written notification to the other signatory parties. In the event the Agreement is terminated, FTA, in consultation with SHPO, shall comply with 36 CFR Part 800 on a case-by-case basis for each proposed project activity.

Execution of this Agreement by FTA, SHPO, PANYNJ and ACHP and implementation of its terms will be evidence that FTA has taken into account the effect of the Project on Historic Properties, has afforded the ACHP and Consulting Parties an opportunity to comment on the Project and its effects on Historic Properties, and has completed all processes in accordance with Section 106 of the National Historic Preservation Act.

WTC Transportation Hub Section 106 Memorandum of Agreement

Execution and implementation of this Memorandum of Agreement evidences that FTA has satisfied its Section 106 responsibilities for the Project, has taken into account the effects of the Project on historic resource, and has afforded the ACHP an opportunity to comment.

LOWER MANHATTAN FEDERAL TRANSPORTATION RECOVERY PROJECTS
COMMON ENVIRONMENTAL PERFORMANCE COMMITMENTS

These common environmental performance commitments are made by the Project Sponsors accepting the Environmental Analysis Framework for Federal Transportation Recovery Projects in Lower Manhattan. As noted in the Environmental Analysis Framework, actual requirements and specifications implementing the commitments will be set forth in each Project Sponsor's public involvement and governmental entities coordination plan, construction environmental protection plan, design documents and contracts.

Air Quality:

Proposed Commitments
Use ultra low sulfur diesel fuel in off-road construction equipment with engine horsepower (HP) rating of 60 HP and above.
Where practicable, use diesel engine retrofit technology in off-road equipment to further reduce emissions. Such technology may include Diesel Oxidation Catalyst / Diesel Particulate Filters, engine upgrades, engine replacements, or combinations of these strategies.
Limit unnecessary idling times on diesel powered engines to 3 minutes.
Locate diesel powered exhausts away from fresh air intakes.
Control dust related to construction site through a Soil Erosion Sediment Control Plan that includes, among other things: a. spraying of a suppressing agent on dust pile (non-hazardous, biodegradable); b. containment of fugitive dust; and c. adjustment for meteorological conditions as appropriate.

Noise and Vibration:

Proposed Commitments
Where practicable, schedule individual project construction activities to avoid or minimize adverse impacts.
Coordinate construction activities with projects under construction in adjacent and nearby locations to avoid or minimize impacts.
Consider condition of surrounding buildings, structures, infrastructure, and utilities where appropriate.
Prepare contingency measures in the event established limits are exceeded.

Cultural and Historic Resources:

Proposed Commitments
Establish coordination among projects to avoid or minimize interruption in access to cultural and historic sites.
Initiate public information and involvement outreach with sensitivity to local cultural resources.
Identify public information outlets that will receive and provide current information about access during construction.
Consult with the New York State Office of Historic Preservation and the New York City Landmarks Preservation Commission regarding potentially impacted, culturally significant sites. Monitor noise and vibration during construction at such sites as appropriate.

Access and Circulation:

Proposed Commitments
Establish a project-specific pedestrian and vehicular maintenance and protection plan.
Promote public awareness through mechanisms such as: a. signage; b. telephone hotline; and c. Web site updates.
Ensure sufficient alternate street, building, and station access during construction period.
Regular communication with New York City Department of Transportation and participation in its construction coordination efforts.

Economic Effects:

Proposed Commitments
Coordinate with LMDC, Downtown Alliance or other entities to minimize residential and retail impacts as required through: a. relocation assistance, as applicable, to persons or businesses physically displaced by the project; and b. focus on essential businesses and amenities to remain in Lower Manhattan.
Add appropriate signage for affected businesses and amenities.

Design for the Environment:

Proposed Commitments
Energy Efficiency/Renewable Energy
Enhanced Indoor Environmental Quality (IEQ)
Conserving Materials and Resources
Environmentally-friendly Operations & Maintenance
Water Conservation and Site Management
Waste Management and Recycling (including during construction)

EXHIBIT D

ENVIRONMENTAL ANALYSIS FRAMEWORK FOR FEDERAL TRANSPORTATION RECOVERY PROJECTS IN LOWER MANHATTAN

In the aftermath of the September 11, 2001 attacks, a common framework of environmental analysis for reconstruction and redevelopment projects in Lower Manhattan can produce substantial benefits for each project, including the avoidance or minimization of environmental impacts and an increase in public understanding. The initiation of transportation recovery projects that are to be undertaken with the $4.55 billion in federal funding to restore and enhance functionality of the infrastructure and support the recovery of the area ("Federal Transportation Recovery Projects") will likely precede non-infrastructure projects. These projects therefore present an early opportunity for implementing a framework for evaluating and minimizing potentially adverse environmental effects, particularly cumulative effects, from other projects in Lower Manhattan that are constructed and put into operation during similar time frames and may affect the same resources (the "Framework"). As such, this Framework, which features a coordinated cumulative effects analysis approach, is offered to assist sponsors of Federal Transportation Recovery Projects ("Project Sponsors") in their environmental analyses.

The Framework for the Federal Transportation Recovery Projects was developed by a group of governmental entities involved with recovery in Lower Manhattan: the Metropolitan Transportation Authority ("MTA"), the Port Authority of New York and New Jersey ("Port Authority"), the New York State Department of Transportation ("NYSDOT"), and the Lower Manhattan Development Corporation ("LMDC"), in cooperation with the Federal Transit Administration ("FTA") and interested federal agencies. It is anticipated that at a minimum, this Framework, as applicable and where appropriate, will be used by the MTA, the Port Authority, and NYSDOT in connection with each of their proposed Federal Transportation Recovery Projects. This Framework will be introduced to additional local Project Sponsors, as appropriate, as additional Federal Transportation Recovery Projects are identified and prioritized. It is intended that, when completed, each Federal Transportation Recovery Project will result in an overall positive impact on the environment.

The temporary waiver of most transportation conformity requirements provided by Public Law 107-230 allows for these projects to proceed with out the need for a full conformity determination. To meet obligations set forth with the conformity waiver, the framework recognizes the need and value of interagency consultation and is consistent with the enhanced interagency consultation procedures during the transportation conformity waiver period.

In light of other reasonably foreseeable transportation and non-transportation actions in Lower Manhattan, this Framework for analyzing Federal Transportation Recovery Projects will establish a consistent set of information and commitments to be fulfilled in each Project Sponsor's project-specific environmental review and documentation. The Framework considers the regulations set forth by the Council on Environmental Quality ("CEQ") and takes into account the guidance in State Environmental Quality Review Act ("SEQRA") regulations, the City Environmental Quality Review ("CEQR") Technical Manual, industry best practices, and public input.

This *Environmental Analysis Framework* consists of the following components:

1. *Green Design, Green Construction, and Sustainability Principles;*
2. *Construction Environmental Protection Plan;*
3. *Public Involvement and Governmental Entities Coordination Plan; and*
4. *Baseline Assessment of Resources & Coordinated Cumulative Effects Analysis Approach*

1. Green Design, Green Construction, and Sustainability Principles

Each Project Sponsor cooperating with the FTA, and other interested federal agencies, recognizes the importance of avoiding and minimizing adverse impacts. Project Sponsors will address their advance commitment to undertake such avoidance efforts. In this regard, Project Sponsors have agreed to develop a common set of Environmental Performance Commitments ("EPCs") that they will each undertake. EPCs are items such as design elements, construction techniques, or operating procedures that will be implemented to lower the potential for adverse environmental impacts. This proactive approach is incorporated into this Framework and will diminish the likelihood of adverse cumulative effects. In addition, each Project Sponsor will undertake additional EPCs appropriate to its project based on the project's particular nature, timing, and scope.

Each Project Sponsor will describe the green practices that will be followed during construction for the following resources/areas of potential impact:

- Air Quality
- Pedestrian and Vehicular Access and Circulation
- Historic and Cultural Resources
- Noise and Vibration
- Business/Economic Interests

Project Sponsors will also set forth the green practices, high performance, and sustainable design features to be evaluated during design of the structures and facilities that will avoid or minimize adverse impacts and enhance overall environmental performance during operation.

2. Construction Environmental Protection Plan

Each Project Sponsor will provide a detailed outline of the EPCs and any other procedures to be implemented during the construction phase to protect sensitive resources that may be affected during construction. This plan will discuss how the initial condition of the resource will be assessed, where applicable; how the construction work will actually be implemented to avoid or minimize impacts; and how the environmental performance of the project will be monitored during construction. This plan will be based on the best available information and the ongoing construction coordination process in Lower Manhattan and a shared Lower Manhattan projects inventory being developed by LMDC. The plan will also provide an effective means for disseminating appropriate current information to the public and other developers.

3. Public Involvement and Governmental Entities Coordination Plan

Each Project Sponsor will describe how the environmental community, relevant governmental entities, and the general public will be involved as the Project Sponsor proceeds with its Federal

Transportation Recovery Project. Each Project Sponsor will develop a public and governmental entity involvement plan that will be coordinated with the public and governmental entity involvement plans for other Lower Manhattan projects. A key goal of the coordination will be to avoid or at least minimize adverse effects on the environment, particularly during construction. In addition, this plan will identify a protocol by which comments received during the construction phase will be addressed; appropriate current information will be provided to the public, including Project Sponsors' project implementation schedules; and coordination with other projects will occur. The process will build on an existing construction coordination protocol among parties already involved in rebuilding Lower Manhattan.

4. ***Baseline Assessment & Coordinated Cumulative Effects Analysis Approach.***
The components of the baseline assessment and coordinated cumulative effects analysis approach to be used by the Project Sponsors in Federal Transportation Recovery Projects are as follows:

- Each Project Sponsor will address cumulative effects, as applicable, as part of its independent project-specific environmental review process.
- The "baseline" to be used for the "No Build" comparison required under NEPA will be pre-September 11, 2001 conditions.
- The "baseline" for environmental review of construction-related impacts for each project will be adjusted to reflect, where appropriate, conditions anticipated to be in effect at the time of construction.
- Project Sponsors will share appropriate information, databases and documentation of the baseline and forecasted conditions.
- Each Project Sponsor will apply a consistent approach for the evaluation of cumulative effects focused on the five following "resources":
  - Air Quality (including the Enhanced Procedures during the Transportation Conformity Waiver Period);
  - Pedestrian and Vehicular Access and Circulation;
  - Historic and Cultural Resources
  - Noise and Vibration; and
  - Business/Economic interests
- The geographic area for analysis will be the area of Lower Manhattan south of Canal Street, but where appropriate, the geographic area may be adjusted for the specific resources.
- Each Project Sponsor will adhere, at a minimum, to the attached set of common EPCs to lower the potential for adverse environmental impacts as listed in Section 1 and above, thereby lessening the potential for each project to contribute to overall adverse cumulative effects.
- As each project matures through the NEPA process, the findings of the project will be incorporated into the cumulative effects analyses for the projects that follow it. As such, the project on which findings have been issued will constitute an "existing condition" for the cumulative effects analysis of the next project.

REGARDING THE ROUTE 9A PROJECT
NEW YORK CITY, NEW YORK

WHEREAS, a Programmatic Agreement for the Reconstruction of Route 9A (Attachment A), executed in 1994 by the Federal Highway Administration (FHWA), New York State Historic Preservation Officer (SHPO), and Advisory Council for Historic Preservation (ACHP), with concurrence by the New York State Department of Transportation (NYSDOT), established procedures for implementation pursuant to Sections 106 and 110(f) of the National Historic Preservation Act (16 USC 470f); and

WHEREAS, the reconstruction of Route 9A (Battery Place to 59th Street) implemented pursuant to the 1994 FEIS was nearly complete at the time of the September 11, 2001 terrorist attacks, however those attacks destroyed an approximately half-mile section of Route 9A in the vicinity of the World Trade Center (WTC); and

WHEREAS, the New York State Department of Transportation (NYSDOT), in coordination with the FHWA, currently proposes reconstruction of the half-mile section of Route 9A in the vicinity of the WTC and lying between Chambers and West Thames Streets that was destroyed or damaged by the attacks on September 11, 2001, and subsequent WTC site cleanup and/or recovery activities; and

WHEREAS, the FHWA, the Lower Manhattan Development Corporation (LMDC), and the Federal Transit Administration (FTA) coordinated the Section 106 determination of National Register eligibility for the WTC Site due to the proximity to the Site of their respective proposed undertakings; and

WHEREAS, the Area of Potential Effect (APE) for the proposed reconstruction of Route 9A has been modified since 1994 and includes, as shown in Figure C-1:

(1) the right-of-way for the Route 9A roadway alignment between West Thames Street and Chambers Street; and
(2) areas along intersecting streets east of Route 9A between West Thames Street and Chambers Street, including locations where construction may occur outside of the Route 9A right-of-way (e.g. foundations of potential pedestrian bridges); and

WHEREAS, historic properties within the modified APE include, as shown in Figure C-1:

(1) the WTC Site, which was determined eligible for the National Register of Historic Places, and documented in the *Coordinated Determination of National Register Eligibility for the WTC Site,* dated March 31, 2004 (Attachment B); and
(2) additional resources listed in or eligible for listing in the National Register of Historic Places, identified in Attachment C; and
(3) the New York City Hudson River Bulkhead as a potential archaeological site.

WHEREAS, it is intended that the 1994 Programmatic Agreement be amended to address: 1) the potential effects of the proposed undertaking to the World Trade Center Site; 2) the identification of additional historic resources located within the Area of Potential Effect (APE); 3) inclusion of the treatment and documentation of the bulkhead; and 4) the increased role of consulting parties so as to fully consider the views of the consulting parties and ensure that FHWA/NYSDOT have the information needed to make a reasoned assessment of how the proposed undertaking affects historic properties; and

WHEREAS, the proposed undertaking is part of the overall restoration of the transportation system of Lower Manhattan, and is an independent undertaking from those undertakings mentioned above and proposed by LMDC and FTA for projects at or adjacent to the WTC site; and

WHEREAS, during the course of consultation to identify additional historic properties within the modified APE an expansive list of consulting parties (Attachment D) participated in the identification process and are hereby recognized under the terms of this agreement; and

WHEREAS, consulting parties under this agreement shall have all opportunities for review and comment stipulated for interested parties under the original 1994 agreement, and accorded to consulting parties under revised Section 106 regulations effective August 5, 2004; and

WHEREAS, in accordance with comprehensive efforts for redevelopment under the Coordinated Construction Act for Lower Manhattan (11700 and 11716-A), signed August 10, 2004, the development and implementation of mitigation measures will be coordinated with other agencies involved in the Lower Manhattan Redevelopment projects; and

NOW, THEREFORE, FHWA, NYSDOT, SHPO and ACHP agree that the proposed undertaking covered by this Agreement shall be administered in accordance with the terms of the 1994 Programmatic Agreement for the Reconstruction of Route 9A and the following stipulations to satisfy FHWA's Section 106 responsibilities.

STIPULATIONS

FHWA, in coordination with NYSDOT, will ensure that the following stipulations are implemented as part of the subsequent planning, design and construction of the selected project alternative:

1. If FHWA proposes a finding of no adverse effect, it shall notify all consulting parties of the finding and provide them with the Analysis of Effect documentation. If within the 30-day review period the SHPO or any consulting party notifies FHWA in writing that it disagrees with the finding and specifies the reasons for disagreement, FHWA shall either consult with the party to resolve the disagreement, or request the Council to review the finding pursuant to 36 CFR 800.5(c)(2)(i) or (c)(2)(ii).

2. If the project is found to have an adverse effect, the FHWA shall so notify the SHPO and the consulting parties accompanied by documentation consistent with that required pursuant to 36 CFR 800.11(e) of the revised regulations. FHWA and NYSDOT shall consult further to develop monitoring and treatment plans and mitigation measures in coordination with the SHPO pursuant to Stipulation II of the 1994 Programmatic Agreement and taking into account the views presented by any consulting parties.

3. Monitoring, treatment and mitigation of the Hudson River Bulkhead:

   (a) Archaeological monitoring will be conducted during construction in the location of the Hudson River Bulkhead in order to identify and document the condition, integrity, depth, and extent of any existing subsurface remains of the Hudson River Bulkhead. Monitoring will be conducted in accordance with a monitoring plan prepared by an archaeologist qualified under National Park Service standards (36 CFR 61). The monitoring plan shall include standard plans for treatment of any anticipated adverse effects to contributing features of the bulkhead. The monitoring plan will be developed and approved in accordance with Stipulation I.E.6 of the original agreement prior to implementation of any ground disturbing activity in the vicinity of the bulkhead.

   (b) Consulting parties will be afforded a 30-day period to review and comment on the monitoring and treatment plan. The standard treatment plan will be implemented if the project is found to have an adverse effect on contributing features of the Hudson River bulkhead. Unless unanticipated effects to contributing features are discovered, implementation of the standard treatment plan shall conclude the

requirements for mitigation of effects to this resource. Unanticipated effects shall be addressed in accordance with 36 CFR 800.13(b)(3) of the revised regulations implementing Section 106.

4. Provisions of the 1994 Programmatic Agreement for the Reconstruction of Route 9A shall be implemented for all other historic properties within the revised APE.

5. In accordance with the revised regulations implementing Section 106 (36 CFR Part 800), consulting parties shall be entitled to share their views, receive and review pertinent documentation, offer ideas, and consider possible solutions together with the Federal agency and other consulting parties. Consulting parties will receive copies of the analysis of effects and proposed treatment plans for each of the additional historic properties identified within the modified APE. Consulting parties shall have 30 days following the receipt of any documentation in which to provide their comments to FHWA and NYSDOT. FHWA/NYSDOT will fully consider any comments from consulting parties submitted within the 30-day review period in finalizing determinations of effect and in developing and evaluating measures to minimize or mitigate adverse effects.

6. Impacts to historic buildings and structures, due to vibrations associated with construction operations, will be minimized through coordination of construction activities associated with other Lower Manhattan projects, the Department's Standard Specifications, and Special Notes to be included in the Contract Documents.
    a. Special Notes to address potential vibration impacts will be developed in consultation with the SHPO. The SHPO will be afforded a 10-day period to review and comment on these Notes.
    b. Measures to avoid and minimize vibration impact will include:
        i. The examination of the conditions of structures and buildings by a NYS licensed Professional Engineer. These reviews will be conducted prior to the commencement of work, at locations and times during construction as determined by NYSDOT, and after the completion of work under this contract.
